Of another salt of lime, the phosphate, notice has been taken when treating of bones as a manure. It will not be amiss, however, to state here, that when any substance is invariably found in any part of a plant or plants, it is right to infer that the perfection of that part of the plant is impossible, unless the substance required is within reach of the plant while growing. Thus the stems of the grasses abound in silex; some of them, the cane for instance, to such a degree as to strike fire with steel, and unless this substance, in the form of silicates, was presented to the plants, they would not be perfect. So it is right to infer that unless soils contain the phosphates, or a supply is furnished for the use of plants, that the cereal grains could never be perfected, as the seeds of these invariably contain large quantities of the phosphates. Phosphates are found more or less in all soils, and when these are deficient, bones form an abundant and accessible source for their supply. It is also found in considerable quantities in all animal and farm yard manures, particularly in the liquid part.

GYPSUM OR PLASTER.

Gypsum is the third principal salt of lime which exerts a powerful influence on plants, and is one of the most valuable of all our mineral fertilizers. Much variety of opinion has been entertained respecting the manner in which it exerts its influence or produces its effects on plants; and these opinions can scarcely be said to be harmonized, even at the present time.—Davy was inclined to consider it a direct food for the plant, as it is found, to some extent, in those plants on which it exerts the most power. Chaptal referred its power to its stimulating agency on plants, produced by its action when dissolved in water. Liebig ascribes its value to its giving a fixed condition to the nitrogen or ammonia which is brought into the soil, and which is indispensable for the nutrition of plants. Dana, to the action of the lime and acid of which the gypsum is composed on the organic matter and silicates of the soil. He says—"It seems almost incredible that so minute a portion of a mineral can act at all; yet how beautifully is the result explained by the principle that plants decompose first this salt; the lime, for plaster is a sulphate of lime, then acts on geine, which is thus rendered soluble; while the acid, the oil of vitriol or sulphuric acid, immediately acts on silicates." It seems very probable that no single one of these suppositions will be found able to account in full for the action of plaster. That of Dr. Dana appears to approach as nearly to a solution as any of them, if we extend his term silicates so as to embrace those combinations formed by the union of the acid of the gypsum with ammonia, after its separation from the lime. If the action of plaster was due to its fixing ammonia alone, then it ought to be equally efficient at all times and places, which it certainly is not; or if it acted directly as nutriment, then its action would be as constant as that of rotted manure or compost, which farmers well know is not the case. Plaster does not act as usefully in the vicinity of the sea, as in the interior; and on heavy wet soils, is scarcely felt at all. Light sandy soils, or loamy ones, are those on which plaster acts the most sensibly; and clover, lucerne, potatoes, cabbages, and the leguminous plants, such as peas, vetches, &c., are the vegetables on which it exerts the most powerful influence. It is much valued as a dress for wheat, not so much, perhaps, for its direct action on that plant, although that is not trifling, as for its effect in securing and promoting the growth of the clover and other grass seeds, usually, in wheat countries, sown with this crop. So marked is the influence it exerts in this respect, that plaster, clover, and wheat, are always associated in the mind of the most successful wheat growers; and its use is the most extensive in the best wheat growing districts of our country. In the minds of many, a senseless prejudice has existed against plaster, on the ground that it the more speedily exhausts the soil, and that the heavy crops at first obtained were the price of ruined farms. It is doubtless true that the man who uses plaster on his farm, who takes from his soils all he can get, and returns nothing to them, will soon find his soils worthless enough. He

who intends to farm it in this way, should avoid plaster; but let any farmer alternate wheat and clover; husband and apply his manures; feed off his clover in his fields, or to his stock in their stalls; let him not spare his grass seeds in seeding, or his plaster in dressing, and his farm will never run down. Such men need not fear plaster.

SALT.

Common salt is an active and valuable manure, and has been used successfully as such, in all parts of the world where it can readily be obtained. In England, the pickings or impure salt is used for this purpose; and many experiments are on record to show that the effect is most marked and decisive. The following is one of a series of experiments instituted by Mr. Sinclair, to test the value of salt as a manure. The soil was light and gravelly.

No. 1. Soil without any manure for four years. Product per acre..... .....13 bush. 26 lbs.
No. 2. Soil manured with stable dung to the previous crop, (potatoes,).....26 " 52 "
No. 3. Soil with 5 bush of salt per acre, and no other manure for 4 years....26 " 12 "

In the opinion of Mr. Sinclair, the effect of salt as a manure was to lessen the produce of straw as compared with other manures, and to increase the weight of the grain.

Prof. Johnston has done more than any other person to extend the use of salt as a manure, by giving to the world his excellent Essay on salt used on soils, and the mass of experiments he has recorded. It appears that salt, in small proportions, promotes the decomposition of animal and vegetable substances; that it destroys vermin and kills weeds; that it is a direct constituent of some plants, and therefore necessary to their perfection; that all cultivated plants of marine origin contain it, asparagus for instance; and that all such succeed better when watered with salt water, than when deprived of it; that salt preserves vegetables from injury by sudden transitions in temperature, salted soils not freezing as readily as those to which salt has not been applied; and that it renders the earth more capable of absorbing the moisture of the atmosphere. When salt is applied as a manure, it may be used in quantities from six to fifteen bushels per acre; although some have gone as high as 50 bushels. Farmers, however, should be cautious how they venture on excessive doses, as an extravagant one could scarcely fail of being atal to any crop. Legrand, in his experiments with salt, found that it gradually improved the crop of barley until sixteen bushels per acre was reached, when it gradually diminished until the amount of forty bushels per acre was reached, when vegetation was destroyed. Salt combined with manure, has proved very efficient; and in the Woburn experiment, the wheat so treated exceeded all others. The most favorable proportions were found to be 45 tons of dung, and five and a half bushels of salt per acre; the manure plowed in, the salt sown with the seed. The experiments that have been made, would seem to indicate that a preferable mode of using salt, in most cases, would be to sow it on the land some weeks before the seed is to be put in. In this case, where lime exists in the soil, a chemical change takes place, at least partially, and muriate of lime and soda is the result. Such a change would seem to be most favorable to vegetation.

SALT AND LIME.

Salt and lime, artificially mixed as a manure, promises to be a valuable aid to the farmer in those positions where the soil abounds with insoluble silicates or geine, and where other manures necessary to produce decomposition or fermentation are not at hand. Prof. Johnston recommends a mixture of two parts of lime and one part of salt, the mixture to remain incorporated in a shady place, or covered with sods two or three months before using. Salt and lime should not be used immediately after mixing, as bad results are apt to ensue; but after being well mixed in a dry state and lying as directed, it may be applied at the rate of from thirty to sixty bushels per acre, either before or at the time of sowing. Mixed with soot, salt acts with great power on roots. Mr. Sinclair mixed six and a half bushels of soot with the same quantity of salt, and used the mixture on lands sowed to carrots. The result was, that unmanured land gave twenty-three tons of roots per acre, and the manured yielded forty tons per acre; and Mr. Cartwright found that where unmanured soil gave 157 bushels of potatoes per acre, 30 bushels of soot and six of salt, made it produce 240 pushels per acre. Dr. Dana furnishes so beautiful an explanation of the manner in which this manure acts, that it deserves a place entire: "By mixing quicklime with common salt, its soda is let loose, the acid combines with the lime, forming a soluble salt of lime, and so long as the soda remains caustic, it has no effect on the muriate of lime, but as soon as the soda becomes mild or carbonate, decomposition of the muriate of lime is produced, and the common salt regenerated. Commencing then with quicklime and salt, we pass to a soluble salt of lime and caustic soda, and from that to mild soda, and to carbonate of lime and the original salt. If these various changes take place in the midst of peat or geine, it is evident that the caustic soda acts upon the geine, and also evolves ammonia from that substance; secondly, that the muriate of lime, in its finely soluble state, insinuates itself among the particles of the geine; that the soda is also equally diffused, and that when the soda becomes carbonated, it produces an almost impalpable carbonate of lime throughout the whole mass, which, by its equal diffusion through the soil with the geine, acts upon the silicates, as has been heretofore explained." To produce these effects, Dr. D. directs to take one bushel of salt and two bushels of lime; to make the salt into strong brine, and with it slack the lime. Mix both well together, and let them remain ten days; then let them be well mixed with three cords of peat, shoveled well over for about six weeks, when it may be used. A quantity of salt sufficient to destroy all vegetation, may be applied to a soil with safety when a few months are to elapse before the crop is to be put on; as the chemical changes which take place, partially neutralize its effect during this time. A small quantity mixed with the soil in each hill of corn, has been found to protect it from the wire worm and the cut worm; indeed there is no substance that insects of all kinds more dread than salt.—It is probable, therefore, that further experiments will show that not the least value of salt is to be found in its preventive properties against these depredators

CHARCOAL.

Charcoal is a valuable manure, and applied directly to the soil in a pulverized state, produces excellent effects. It acts by rendering the soil more permeable to atmospheric air, by absorbing and retaining for the use of plants the ammonia of the atmosphere, or such as falls in showers; by rendering soils with which it is incorporated warmer; and by furnishing a constant supply of carbonic gas to growing plants. The great productiveness of what are called coal hearths, or those places on which charcoal has been burned, has long been a common remark, but this has been commonly attributed to the ashes, burned earth, &c. on such spots, rather than the coal. The use of coal alone, however, shows that though these other matters are not without their value, the great additional fertility of these places is mostly owing to the coal. Immense quantities of this substance are wasted in the vicinity of forges, furnaces, smith's shops, &c. which would be of great value, were farmers to collect such refuse or dust coal, and apply them to their farms. On heavy soils in Europe, it has long been customary to pare the surface, and burn the turf so collected, taking care to incorporate as much of the clay soil as will consist with the ignition of the turf. This burnt mass of clay and ashes is scattered over the ground, and is found to make a valuable dressing on such soils.

OTHER MANURES.

It is impossible to particularize all substances that may be used as manure. It is evident, from the definition first given, that they would embrace all animal matters without exception; all excrementitious secretions of animals, and all vegetable ingredients in one form or another, together with a few of the mineral salts, such as the alkalies, silicates, &c. Thus, oil-cake, bran, yeast, brewers' grains, putrid meat, in short any substance that can be classed under the above divisions of matter, may be useful as manures, and this fact should induce great caution in their preservation and application.—Whatever may be the present condition of a particle of matter, if it has ever formed a part of an organic body, it can again become such under circumstances favorable to such a condition.

In the preceding rapid sketch of the principal substances valuable as manures, the best methods of preparation and use have also, to a considerable extent, been given. All then that would now seem necessary for the purpose of this Essay, is a condensed view of the principles laid down, with such incidental topics as have been passed over, but of which a notice appears necessary.

PREPARATION AND USE OF STABLE MANURES.

As the common farmer must always rely on stable or farmyard manure, as his principal means of fertilization and renovation of his soils, it is to these, to their preparation and use, that his attention must be principally directed. It is an important question for him to decide, whether he should apply his manure in a long state, that is, apply it fresh from his stables and yards before undergoing decomposition, or let it remain until the litter and straw has fermented and become rotten, before using it. Some remarks on this topic have been made in the preceding pages, when treating of such manures, but its importance will justify their extension in this place. It has been said that rotted manure contains more geine or humus, weight for weight, than unrotted or fresh manure. This is probable, but to make this test decisive, equal weights of dung should be taken while fresh, one analyzed at the time, and the other when fermented and rotted. This course, it is believed, would show a result in favor of the unrotted. There can be no doubt, however, that straw, stable litter, &c. should be partially fermented before using, and the moisture necessary for the process should, if possible, be the urine of the animals or the drainings of the yards. Straw, in dung intended for a particular crop, is of little use unless the fermentation has far progressed; and a distinguished German farmer has asserted that he considered straw as of no consequence in manure, except as acting the part of a sponge to retain the fluid parts of the animal manures. There are some exceptions to this remark, as when straw is applied to heavy clay grounds before rotting. In this case, when plowed under, it gives a degree of porosity to the soil, absorbs part of the moisture, and acts the part of a valuable amender, while it is eventually converted into a manure, or a source of carbonic gas. Where the unfermented dung of the yard or stable is applied to the soil, it should be covered at once by the plow, that the gases liberated in fermentation may not be lost, and that the moisture necessary for fermentation may be secured. When rotted or fermented, the covering is not of so much consequence, and it may, without loss, be scattered on the surface and mixed with it. If used without fermenting, it should be applied to hoed or summer crops, such as corn or roots, as these are in that state while the manure is at the height of its fermentation, when forcing manures are the most useful; but if applied to the smaller grains, they are most active when matter for the perfection

of the seed, not the enlargement of the straw, is most needed, and the last is increased at the expense of the first. Taking all these circumstances into consideration, there can be little question that the most economical way of making and using manures, is to convert the stable and barnyard manure into compost, by the addition of peat, swamp muck, cleansing of ditches, wash of roads, leached ashes, or even common loam or earth, taking care, when the manure is wanted for heavy soils, that the earth used in the compost should be as light or sandy as may be; and where the soil is light, that the compost earth should be marly clay. Into such a compost heap, all weeds, straw, litter, animal matter of all kinds, night soil, &c. &c., may be thrown, and upon it all the wash of the yards and urine of the stables may be poured; and if the animal and vegetable matters as they accumulate, are kept covered and moist, the fermentation will go on successfully; the alkalies and salts of the animal matters will act on the vegetable part and saturate the earths used, and the whole will be converted into manure of the most valuable quality.

PREPARATION AND USE OF COMPOST.

The labor of preparing compost, it is true, is much greater than merely drawing it from the yard, but the quantity is so much increased, and the quality so much improved, that it is the most economical in the end. The only method that can compare with it, is to place these matters over the yard, and let them be composted or fermented in that place; but there will always be a great waste in this way; and where turf or vegetable mold is used for composting with the animal manure, the compost heaps can frequently be made where they are to be used, and the labor of drawing materials greatly lessened.—Bommer's patent manure is only compost made in a scientific and accurate manner, every part of the process so managed as to produce a perfect fermentation, without the loss of any of the valuable parts of the constituents used. From a knowledge of the process employed by him, we are able to say that where his directions are followed, a powerful and valuable manure cannot fail to be produced. The fundamental principle upon which composts have been made, is that of impregnating the earths used in the process with the soluble salts and the gases, which, in the ordinary methods of rotting, are wholly or partially lost to the farmer. The discussions which have been carried on, as to the propriety or impropriety of burying manures in the soil, have arisen from not stating the kind of manure to be used. The solid and soluble parts of manures have a tendency to sink into the soil; the gases evolved in fermentation a tendency to rise. The true principle, then, is to bury the unfermented matters no deeper than is necessary to secure the moisture required for fermentation, while the fermented or decomposed dung, having no fertilizing gases to lose, may be mixed at once with the surface earth. Some of the greatest crops of Indian corn ever grown in the United States, have been produced by placing a heavy dressing of unfermented manure on turf land, and turning it under with the plow. The surface is then rolled to press the sod close upon the manure, and afterwards harrowed, to loosen the earth for the reception of the seed. Into each hill, a small portion of fully rotted manure or compost is put at planting. This promotes germination, gives the young plant a vigorous start, and by the time the roots have penetrated beyond this, active fermentation has commenced in the long manure, and thus fertilizing matters are furnished in the greatest abundance when most wanted by the plant.

USE OF LIME.

Of the mineral manures used, lime, as has been already stated, is the most important, and under all its forms, is extensively used in Europe and in this country. The German farmers of Lancaster, Chester, and the adjoining counties of Pennsylvania, use lime more extensively than in any other part of this country. Considerable discussion has been had at different times as to the comparative value of limes that contain magnesia, or such as are free from it; but the value of lime as a dressing for soils, seems to be every where conceded in those districts where it has been used. It appears as the result of experience, that lime produces the best effect on what are called stiff loams, or loams inclining to clay, and in which a good proportion of decayed organic matter is found. It is found, too, that it operates more favorably on soils natural to oak and its kindred trees, such as walnut, poplar, &c. than on those where the beech, elm and maple constitute the principal timber. It is singular that the richest limestone lands, as they are called from being based on this rock, are frequently those on which heavy dressings of lime operate like a charm. If used as a top dressing, lime is usually applied to the sod in the fall; but the practice most approved, is to lime the corn ground in the spring, on the inverted sod. Manure is applied to the wheat crop after lime. The quantity of lime used varies much. There is no doubt it has sometimes been used in excessive quantities; and when used on soils nearly destitute of vegetable matter, can produce no good effect. On a medium soil, fifty bushels per acre may be considered an abundant dressing; but three or four times that quantity is sometimes used. The best method of using lime, is to take it from the kiln, unslacked, and deposit it in heaps in the field where it is to be used, not more than three or four bushels in a place; and either slack it by pouring water over it, or, which is better, by covering each pile with earth, and letting them slack by the moisture thus furnished. When sufficiently fine, the earth and the lime are mixed by shovelling over, and the mass is then scattered over the land to be dressed. The soil should be well harrowed after the application of lime, to incorporate it with the surface earth.

NECESSITY OF MANURING.

It is obvious that the manuring of a farm should only be limited by the ability of the owner. On a plentiful supply of manures, is depending the fertility of his soils, the amount of his crops, and consequently the extent to which his labor is rewarded. There is no expenditure on a farm so safe as that for manure; and the labor required to increase it, is never labor lost; at least, if directed by an ordinary share of agricultural knowledge and skill. Every source of supply should be made available; nothing capable of fertilizing should be lost. The farmer who takes from his soil more than he returns to it, is surely impoverishing it; and if he escapes such a calamity himself, he leaves to his successors a worn out farm. If he returns as much as he receives, his farm will retain its original fertility only; but the true farmer will scarcely be content with this. To increase its fertility, and the amount and quality of the crop taken from the soil, should be the aim of the husbandman. This done, his labor is lessened, his profits are greater, his farm is worth more; nor must the pleasure arising from beautiful fields, golden harvests, fine animals, accumulating prosperity, be omitted in making up our estimate of the advantages of successful culture. Manure may be a homely subject, but on its preparation and use every thing is depending. Without it, the deep green of our pastures, the golden yellow of our corn fields, and the fine beef and white loaf of our tables could not exist. To the farmer, manure must be the first thing, and it must be the last thing; with it he can do every thing; without it, nothing.

"Honor and fame from no condition rise."

There is but one way of securing universal equality to man—that is, to regard every honest employment as honorable, and then for every man to learn, in whatsoever state he may be, therewith to be content, and to fulfil with strict fidelity the duties of his station, and to make every condition a post of honor.—*S. W. Farm.*

FARMERS' CLUBS.

Of the various methods that have been adopted to awaken inquiry among farmers, promote investigation, furnish the means of interchange of thought, and create social harmony and good feeling, few have been more successful than the associations known by the name of farmer's clubs. What the agricultural society is to the county, these are in many respects to the neighborhood; and the good results, wherever they have been instituted and sustained, are not less apparent. The effect of such associations does not so much depend on the numbers, as on the spirit, zeal and intelligence of the members, although where the right feeling prevails, the more that combine the better. There are few agricultural neighborhoods where a dozen men cannot be found willing to meet once a month to compare opinions, and communicate the results of their experience and observations.—Even half a dozen, if they are men of the right stamp, will make the meetings of such a club most interesting and instructive. Such meetings are the places to discuss and settle all points of a practical character in agriculture; soils, their qualities, and the crops best adapted to each kind; agricultural implements and their improvement; new theories, and their rationality or practical bearing; questions connected with agricultural reading or education; in short every thing belonging to the farm, the orchard or the garden, will be found a suitable and fruitful topic of remark. Such a club should possess an agricultural library, supported by the contributions of each associate, and open to every member, the books and periodicals to be subject to such regulations as to afford security against loss. The best foreign as well as domestic works on agriculture and its kindred sciences might always be found, and all the most valuable of our periodicals useful to the farmer placed on file for reading or for reference. To each individual the expense would be far less than if his labors for information were alone and unaided, and the mutual advantages greater. Another of the benefits resulting from such an association would, or it might, be the formation of an agricultural museum, embracing specimens of the various soils cultivated by the members, or any of those remarkable for their fertility or otherwise; specimens to illustrate the geological character of the district, and show the bearing this science has on agriculture; specimens of the various kinds of grain and cultivated plants, whether remarkable for size, novelty, or their valuable qualities; fruits, roots, &c. according to the season; together with all such matters as are calculated to interest and instruct a body of men; the whole, as far as possible, to be preserved for the benefit of all. We have merely thrown out these few hints, in the hope that some of our spirited farming neighborhoods may be induced to further develop them and reduce them to practice. Wherever, in Europe or in this country, this or kindred plans have been adopted, the results have been most happy, and the cause of agriculture has received a decided impulse.—*Cultivator.*

CORN COBS.—The most economical method of disposing of corn cobs, is doubtless to pound them up and grind them with corn, for stock.—But as this is often neglected, another excellent mode of disposal is to soak them in pickle and feed them to cows or other cattle in the yard.—A large tub, formed by sawing a hogshead in two, near the middle, should be placed in a convenient place, near the yard, and being filled with cobs, a sufficiency of warm water, strongly impregnated with common salt, should be poured over them to render them soft and palateable to the stock.

Most animals devour them greedily in this state, but when it is not too much trouble, grinding into meal is much preferable. There is but little difference in the value of pure corn meal, and that made of corn and cobs, for feeding most animals. The meal of the cob also makes excellent puddings.—*Maine Cultivator.*

MANAGEMENT OF FARMS.

There are far too many in our community who, relying solely on the present returns of their farms, plant nothing but cotton and corn, and plant with the belief that it is cheaper to buy and clear new lands, than to improve or keep in good heart their present cleared lands. In making our remarks on this subject, we write not from theory, nor from our limited practice, but could make a reference, known to many of our readers, that is as strong in proof of the grounds we take as any thing could be. We hold, what we have oft times repeated, that the farmer who can show a clear gain in a series of 10 or 20 years the greatest, when especially if there be much of it in his real estate, is the best farmer. We furthermore believe it is a subject more important to our friends than any other we could call to their attention, as it includes the whole subject of good farming—excepting due economy in his expenses, and the proper education of his family. This subject not only includes fair crops, good plowing, clean and perfect cultivation, rest of land, rotation of crops, manuring, but the proper care of stock, as to feeding and preparing an abundance of food for every thing, and making quantities of manure. We cannot give the hundredth part of all the minutiæ of plowing and hoeing, planting and gathering, &c. &c.; but will touch on the outlines of a system, *that is acted on*, which is perfectly compatible with a cotton farm, and the only feasible one that we can think of, and we do profess to have given the matter our thoughts in every possible bearing. There is one thing we beg to say, with the wish that our interest should be so construed in our favor, as that our readers will give it their thoughts at least. We read no political work of any description, and seldom talk on politics. Our friends, knowing we are "Berkshire mad," indulge us with conversing on this subject, and we read every day more or less on agriculture, and think on it all the time.

We will take a farm of any dimensions, supposing it be well cleared, with good fences, having enough stock of every description, with tools, &c., and plow horses for one half the hands, which is about usual. Suppose the farm to be 100 acres of cleared land, it being in round numbers and easily divisible. This 100 acres will require 7 hands to cultivate it as is frequently done—9 acres in cotton and 4 in corn, which gives a crop of 6 to 7 bales, and about 125 bushels of corn per hand—4 or 5 horses on the farm. We would advise that the farm be divided into 4 fields of 25 acres each—one planted in cotton, one in corn, one in grain—the fourth to be at almost perfect rest, which will be better explained after awhile.

Three hands, with a horse each, can cultivate this land, and will make the same per hand crop of cotton, with nearly double of corn, and a large per hand crop of grain—place the other hands to clearing, which will enable the farmer to bring into his field one or two more of his hands the second year, and so on until he gets all seven in the field. In the mean time he will necessarily lose a portion of his crop; but as his provision department is so much more ample, he will make more than his crop calls for, as he has been accustomed to. The second year he will plant his rested land in cotton—cotton land in corn, corn land in oats, and his oats land will rest, and so on through the rotation.

By feeding his stock so much better, as his provision will enable him so to do, he will be enabled to manure his corn yearly, at least in the hill. Thus in four years he will have added a little to his permanent improvement. By planting peas in his corn, there will be another addition to his farm every four years; the peas will come up in the spring on his oats field.—This, with the stubble and grass, will be another addition: the rest, together with grass and weeds on this last quarter, will be another addition. Thus we have three-fourths of the farm well manured yearly.

We would, after gathering our corn, turn stock into pea field—say October 1st; herd them nightly in lots, and feed with cotton seed and shucks. They would thus do well until say middle of December—then use the better food at night, and give them access to grain field until 1st of March, by which time the field in rest might, if a favorable season, be used for two months, always removing them in time, that a growth of grass and weeds sufficient to protect the land should be on it before the heats of summer injure the land. The stock may soon be turned into the grain field, or it might be preferable to turn into range, if good, or if not, to feed for a month or so—then, in August and September, back on the rested land. We would thus have dropped in the fields or in the lots all the manure, thereby returning to the land nearly every thing taken off; and if we consider the agency of the atmosphere and gases, carried into the earth by the rains and plowing, we do absolutely give to the land more than we take away. If an individual be out of debt, we hold that before the fourth rotation comes round, he will have made more dollars and cents out of the land, besides having improved his land and stock in value, full 50 to 100 per cent.

We could name a farmer who, in following in the main this system, made last year 130 bales of cotton, and 1500 bushels of corn that he has not been able to consume with twelve hands.—Can this be beaten in the length and breadth of our land? He sells pork, and has the finest and fattest cows we have seen in many a day. Bear this in mind, he has a work horse to every hand, and in a push turns out his cook and follows the fourteenth plow himself. He has more implements than some of our friends who may work twenty-five to thirty hands. Is this not true economy? He, making many of his tools at home, not only feeds double the number of horses, but has as much corn to sell as many make with the same number of hands, and with all this turns his stock into an hundred and fifty acre field of grain, not having cut more than will give him seed, gathers peas enough to plant not only his corn field, but to sow down 40 or 50 acres of pasture land, with ½ bushel per acre. We rejoice more in ferreting out this *brother* of ours, than we have for a length of time at any thing—as we have a living witness that we are not half so "Berkshire mad" as many of our shovel-plow, hoe-working good folks of the "ancient regime" would have us be. We know full well that were we to give all we saw and heard in spending at that place a few hours, that many cross masters would lay down their rod of dignity, and begin to learn. We have thought this matter to be so plain, "that the wayfaring man, though a fool, shall not err therein;" it appears to us to carry a demonstration with it, as self-evident as that a straight line is the shortest distance between two given points, or that two sides of any triangle is greater than the third. But as evident as this appears to us, there are those who believe to the contrary, and are putting good farms into the very condition of those they left in their native land—which farms are now being improved at a cost far exceeding the value of ours. Will they not learn a lesson ere it be too late. Will they continue to rob their children, and drive them to distant lands, as they have been driven by their forefathers, who had not the same lights that we all have now? We trust not, we hope not, we believe not. 'Tis for this that we now labor, while many, probably all, of our industrious readers are in bed.—*Southwestern Farmer.*

HEAVES—Do you know of any effectual remedy for heaves in horses? If not, perhaps you may consider what follows as worth nothing. I have a valuable horse—one of a pair—which threatened, more than a year ago, to become utterly useless in consequence of this complaint. At the expiration of the last grass season, I was induced to try top-stalks instead of hay, and the result has been that the animal is entirely relieved, nor have I the least expectation that the disease will recur to any extent, so long as this diet is adhered to. Permit me to add, that I have for years been in the practice of giving my horses each an ounce of fine salt every other day; and that I have good reasons for believing that their health is greatly promoted by it. In reference to stalk fodder for horses, I should like to inquire through your paper, of southern gentlemen, whether in that part of the country where hay is not made, they ever have heaves among their horses. If they do not, I shall consider my experiment conclusive.—*Albany Cult.*

TRANSPLANTING TREES.

Success in transplanting trees depends much on the treatment they receive in that operation. On removing the trees from the nursery, care should be taken to prevent the roots from drying previously to planting them, otherwise they may receive considerable injury; and when they are to be transported to a distance, particular care should be taken to preserve them from drying winds before packing. Immediately on their receipt the bundles should be unpacked, the roots well watered and "laid in" until the ground in which they are to be planted be ready to receive them. By laying in, is to be understood the making of a trench sufficiently large to admit the roots, into which they are placed; the earth having been previously made fine is then filled in around them and a gentle watering given, in which situation they may remain with safety until planted.

The holes in which it is intended to plant them, should, for an ordinary sized nursery tree, be from 2½ to 3 feet in diameter, and about the same depth; the earth from the bottom should be thrown aside, the place filled up with good compost or black mould, (no fresh stable manure should be used in the compost.) The tree should be planted one or two inches deeper than it stood in the nursery, the roots and fibres being spread out horizontally, and during the process of filling in the earth, the tree should be shaken several times to admit the soil between the roots, and also to fill up any cavities that might otherwise remain. The earth should then be trodden down and gently watered; in a short time it will have settled, and any hollows that may have formed, should be filled up—finishing by forming a basin around the trench to receive the rain or watering which it may be necessary to give it, if the ensuing season should prove dry; to prevent the winds from loosening the earth around the roots, the tree should be secured to a stake by bands of straw.

The proper season for transplanting trees in this latitude, is from the middle of October to the first or middle of May. Trees transplanted in autumn should have the roots a little protected during the first and most trying winter. This protection may consist of a few inches of litter from the stable, placed around their trunks and over their roots. Moss from the meadows or evergreen boughs are, however, preferable for delicate plants, as these substances, being almost incorruptible, never injure what they were designed to protect.

"We have observed," says the Genesee Farmer, "in regard to transplanting fruit trees, that we have rarely lost one that stood in cultivated ground, where the hoe was introduced several times in the course of the summer; but on the contrary, where the trees were set in grassy land, or where the cultivation was neglected, our losses have been considerable. We therefore advise, in order to secure the safety of such as have been planted out, either in the last autumn or spring, to have the ground well hoed round them once a month; and if it be done every fortnight, it will be still better. The labor will not differ very materially from hoeing a hill of corn. It is worthy of notice, however, that the oftener it is done the easier it is to do—because the soil will be kept loose and mellow.

"To water trees in that condition may sometimes be useful; but we are not free to recommend it very highly. A loamy soil that is much watered soon becomes hard; the surface is glazed, rendered in a great measure impermeable to the air, and is consequently no longer

capable of affording, in dry weather, the necessary nourishment to the plant. The sources of its fertility are obstructed. This may be better understood by some of our readers, when we state on the authority of Sir Humphrey Davy, that a soil in the greatest degree absorbent, exposed to the atmosphere till it becomes dry to the touch, still contains moisture equal to one-eighth part of its whole weight. This is discoverable by subjecting it to a heat indicated by 300 degrees of Farenheit's thermometer. Now all water not chemically combined, but only *adhering* to parts of the soil, is in constant use in vegetation: and the one-eighth part referred to is of this kind. If we estimate common fertile soils, however, as containing only one-twelfth part, then in 400 pounds of soil, even when it is dry to the touch, we shall have 33 pounds of water in store for the use of vegetation; and it is particularly worthy of notice, that such soils, when deprived of a portion of this by plants, procure a fresh supply *by constantly absorbing water from the atmosphere*, where it exists in the state of vapor. In effect a good soil is a perpetual fountain, even in dry weather.

"From these statements it must be evident, that unless the ground is frequently cultivated and kept mellow, so that between its particles the air can pass in, the latter cannot impart the moisture which it holds in solution; but when the soil is freshly broken, minutely divided, and prevented from conglomerating, these invisible springs are preserved in order, and plants that drink from them will long resist the drought.—Let the hoe, then, be freely and frequently used.

Mississippi Valley Farmer.

WHAT IS THE BEST MODE OF HARNESSING OXEN?

Mr. Breck—In your paper of last week, there is an article taken from the "Miss ssippi Valley Farmer," on the "Value of Oxen," which I have read with great pleasure. I find in that article the following paragraph:

"The value of the ox for labor is much increased by substituting the collar and traces for the common wooden yoke and bows. The horse collar *reversed*, or turned the bottom up, makes an exact fit for the neck of the ox, if it be made of a suitable size. We have been assured by those who have adopted this method of gearing, that it has with them a decided preference over the common method. The following are some of the advantages: Whether the oxen be geared singly or in pairs, they travel with more ease to themselves; and there is consequently an increase of speed in travelling; there is less liability to chafe and gall, and what many would consider the most important advantage, there is an addition to the strength of draft of at least ten per cent."

I have often wondered when seeing the patient ox with his head bowed down, and his neck overloaded with a heavy yoke, why this barbarous and inconvenient mode of gearing him was kept up—the most awkward and ungainly mode of tackling, if it may be so called, in the whole economy of farming.

It seems that gearing with a collar has the advantages mentioned by the intelligent editor of the Farmer, and it strikes me there are others that he has not mentioned: they are, that the collar allows more perfect freedom for the head, and therefore there must be greater ease in travelling. The collar, too, spreads the draft over a greater surface, and brings the draft in the right place; and if the gearing has also breeching straps behind, the load is prevented from coming on the heels of the cattle in going down hill.

I wish some one of your intelligent and observing correspondents would enlighten us on this subject, and, if possible, give us the results of their experiments. I believe a better, safer, more comfortable, more convenient, and in the long run, cheaper mode, could be devised, for tackling this useful animal. Many a time when he is goaded along and vexed with vituperation, he is suffering from a chafed neck, rendered callous almost by the constant action of the heavy yoke, but not so callous as not to be galling and oppressive to his neck.

If this mode, too, will allow of working him single, and his gait can be improved, so that he will walk faster, and release his head from the pounds of wood he carries, (and I think such improvement can be made,) why not adopt it?

Why will not some agriculturist who has a yoke or two of oxen, try the experiment? Why will not others start in this matter? What are the objections to the collar for oxen? What are the advantages of the old mode, or rather present mode of attaching him to his load? Why should it be persisted in? Will some of your correspondents, I ask again, enlighten us on this subject? Yours, truly,

A Cultivator.

Remarks by the Editor.—The customs and usages of our fathers, in relation to the modes of operation in farming, have been followed by the children with as much obstinacy as though their usages and opinions were infallible and could not be improved upon, and to doubt the soundness of their views, would be denounced almost as heresy; but it is gratifying to know that a spirit of inquiry is abroad, and that not only the children but the fathers, are beginning to look around and inquire, how can we improve upon the past and the present mode of cultivation? How can we add to the comfort, and increase the profit and improve the beauty of our animals? &c. "A Cultivator" has made some interesting inquiries, which we hope some one who has experience in the management of oxen will answer. We have often been inclined to believe that an easier mode of drawing than by the wooden yoke, might be adopted, but as we have had but little experience in this matter, it does not become us to suggest the improvement. It would be rather hard, we think, to bring into general use any other fashion than the yoke, even though it should be proved that the collar was the best; but will not some one make the experiment of the collar, as well as answer the inquiries of "A Cultivator."

New England Farmer.

SMALL FARMS.

We are glad that the farmers throughout the country are discussing this subject with so much interest and earnestness.

For a long time we have indulged in extravagant fancies in every thing. Large possessions and large wealth—these are counted essential, and few were the men who could toil contentedly on small farms, and be satisfied with a limited business; but the experience of the last few years has taught us all that money, beyond that point which secures us independence, is not an element of happiness or progress. When sought for, for its own sake, it is ever a means of evil. Nor can it be otherwise if grasped at to gratify a low, sordid ambition. These truths have made slow, but sure, progress among all classes; yet among none more than the agricultural interests of the land.

We may mention the growing disposition on the part of farmers to possess only as much land as they can cultivate well, as proof of these remarks. And we cannot but rejoice at it.—For, if rightly directed, their influence will ever be exerted for the substantial good of all—since it possesses, from a variety of causes, that admixture of wisdom and prudence, which is unwilling to run foolish risks, or try hazardous experiment in governments, or the policy of government, yet which is never backward in making changes whenever, in reason, they are called for, or urging reforms when existing evils demand them. Just views at home insure just views generally, with regard to every thing else. And when the farming interests practise on their own soil whatever a wise economy, comfort and real independence may demand, we may feel assured, not only that their influence will be rightly directed, but that they will see to it that those virtues are practised in our public affairs.

And as a general rule, the possession of as much land as may be well cultivated will help to establish these virtues. First, the farmer who is so situated can apply his industry better; second, he can employ all his capital, he can do no more, and obtain a surer and steadier return from both; third, he can secure more of those comforts which tend so much to improve and civilize all of us—a good dwelling, good outhouses, good fences, good cattle, greater fertility of soil, and better knowledge of his business. Nor is this all. When men measure themselves thus, by what they can do, and are zealous to do it, they are not so apt to be led astray by speculation, by avarice, by social display, or any of that class of evils which so much disturb and distress society. They love the earth they till, they are content to till it, being proud of the labor of their hands; they find and feel under these circumstances, that they can do more good to others, and enjoy themselves better, because necessarily they will look more to what is *in* a man than what is *around* him, to character, rather than to the number of acres he may own, or the wealth he may possess.

It is a national blessing, in every way, to multiply small farms. Show us a state that has the most of them, and we will guarantee to find there the greatest amount of substantial wealth and real happiness. Economy, it is said, is a mine of wealth. Energy is the means to supply this mine; and as the truest economy and the stoutest energy are employed on them, the more small farmers we have, the greater will be the strength and wealth of the nation.—*Ex. paper.*

Great Yield of Wheat.—The following note from from Mr. Dickinson, of Onodaga Hollow, will show the course adopted by him in producing his crop of 52½ bushels of wheat per acre, the present season. There can be little doubt that much more labor is expended in producing the wheat crop generally, than would be necessary if the grounds were properly prepared once for all, made clean, and kept clean, so as not to require fallowing as cleaning process. We have as yet heard of no yield this year that has exceeded this.

W. Gaylord, Esq.—I send you a hasty account of the preparatory treatment, nature of the soil, &c., in the case of the wheat crop to which allusion has been made. Two years since, this month, I purchased the farm on which I reside, and commenced working it the next spring. There had been no clover seed used on the place by the occupant before me, except on the lot where the wheat was grown by me. The field had a crop off oats taken off, and was then seeded to clover. In the spring when I came on the farm, the clover was small and thin, and I sowed on it 1½ bushels of plaster per acre. The second week in July, I mowed off the clover for hay. The last of August, I plowed in a large growth of clover, and harrowed it thoroughly. On the 6th and 7th of September, I sowed on one bushel and three pecks of Canada flint wheat to the acre, and harrowed it in. The soil is a friable black slate or loam. The wheat in the whole field was remarkably equal, and the crop per acre as stated.

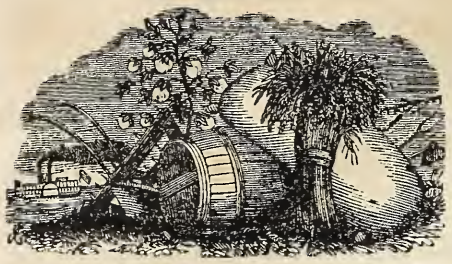
Yours, truly, O. Dickinson.

Onondaga, September 12, 1843.

Albany Cultivator.

We have always thought that the product of wheat, per acre, was susceptible of being brought up to from 40 to 50 bushels, and the occasional yields which we hear of above that standard, serves but to confirm us in our opinion; and we are sure that by proper care in the pulverization and preparation of the soil, and a liberal sowing of seed, that that amount of product can be attained.—*American Farmer.*

Hardened round us, encasing wholly every notion we form, is a wrappage of traditions, hearsays, mere words: we call that fire of the black thunder-cloud electricity, and lecture learnedly about it, and grind the like of it out of glass and silk; but what is it? Whence comes it? Where goes it?—*Carlyle.*



WEDNESDAY, NOVEMBER 22, 1843.

BACK NUMBERS.—All new subscribers to the "Southern Cultivator" can be supplied with the back numbers.

OUR SECOND VOLUME.

The first volume of the "SOUTHERN CULTIVATOR" is drawing rapidly to a close—only two more numbers will be required to complete it—when we shall enter upon the second. It is, therefore, a fit and appropriate occasion for us to make an appeal to the Agriculturists of the South, to stand by, and aid and sustain us in the enterprise. We do not appeal alone to the agriculturists, but we appeal to every friend of agriculture, to lend his aid in sustaining the work. Prompted by an earnest solicitude for the improvement of the system of agriculture in our native State, as well as the entire South, we entered upon the publication of the work, hoping rather to make it an acceptable medium of communication for the planters of the South, than the vehicle for diffusing our own crude ideas upon the subject of agriculture. We had long felt the necessity for such a work—a work adapted and devoted to the promotion and improvement of Southern agriculture, while it should be afforded so cheap as to place it within the reach of every planter—and feeling rather mortified at the reflection that the entire South furnished no such work, we determined to embark in the enterprise—to make the experiment—and see whether the planters and friends of agriculture, for whose immediate benefit it was designed, would sustain us in our efforts. Thus far, although the patronage extended to the present volume has quite equalled, if not surpassed, our expectations, it has been barely sufficient to defray the actual cost of publication—affording us no remuneration for our own labor and attention. It remains, therefore, with the planters to determine whether this state of things shall continue; to determine, in short, whether "*the laborer is worthy of his hire*," and, if so, to mete out to him even handed justice. It has been aptly and truly said, that "it is the reward, or the hope thereof, which sweetens labor," and as we are not yet enabled to gather together and count the fruits of our labors in this behalf, we invoke the friends of agriculture to extend to us such aid in the circulation of our paper, as they may deem it worthy to receive at their hands. We have every disposition, and are entirely willing, to toil on in behalf of the interests, and for the improvement of the condition, both morally and physically, of our own native South; but, as the well tempered steel cannot resist too much tension, we, too, must yield when too great a burthen is imposed. We cannot, therefore, prosecute a labor which holds out to us no inducement in the shape of reward; and we are quite sure the generous and noble hearted planters do not desire such a sacrifice of time and labor at our hands, but rather that they desire to see us amply, yea, abundantly and liberally, rewarded. With a perfect conviction that this is the feeling of every friend who has read or seen the "SOUTHERN CULTIVATOR," we shall enter upon the publication of the second volume, indulging the sanguine hope that our efforts in behalf of the great agricultural interest of the South will not go unrewarded, but that our friends will lend their efforts to extend its circulation and increase its usefulness. Satisfied that this is the feeling among the planters who have read the work, we feel no delicacy in asking each of our present patrons, to imagine us before them in person, with hat in hand, and, after having made our best bow, soliciting them to call and see their neighbors, and ascertain if they, too, will not become subscribers to the "Southern Cultivator." And allow us to assure you, if each of you succeed in obtaining only one subscriber, you will afford us such relief as will make our heart leap for joy. Some of you can get two, some ten, and others twenty, if you will only make a little exertion. Will you not, then, unite your energies in behalf of the Cultivator, the cause of agriculture, and your own interests? We hope you will; indeed, we had almost said we know you will. The price of subscription is only ONE DOLLAR per year, as you all know—a price which every planter can afford to pay; and as every planter who studies his own interest, ought, in justice to that interest, to take an agricultural paper, we hope that all such planters will have their names enrolled on our subscription list. We need not trespass upon the consideration and indulgence of our friends, the Agricultural Clubs of the State, for we feel quite assured that they will not neglect us in this hour of need.

CLUBS.

We remark, in conclusion, that in order to offer every inducement to clubs to subscribe, the following terms will, in future, be adopted:

6	copies	for	$5 00
25	"	"	20 00
100	"	"	75 00

These terms, certainly, should meet the approbation of every friend of the work, and, we trust, will excite an increased zeal in its behalf.—With these remarks, we commit the work to the hands of its friends.

☞ We hope that those papers with which we exchange, will copy the foregoing, with such comments as they may deem proper.

FOURTH CROP OF APPLES.—The Alabama Monitor says, "We have seen a lot of apples from the plantation of Mrs. Colter, of Pickens county, of the fourth crop this season. Since the first bearing in June, three other crops of blossoms have matured into fruit. We noticed a little branch on which was a cluster of six apples, from the size of a guinea egg to that of a plum, all perfectly ripe.

Last year our fellow citizen, Capt. Dearing, produced a third crop of apples from the same tree, a circumstance generally noticed in the public prints as very rare; but it seems a Lady-horticulturist has done still better, and no doubt attained the utmost limit in apple crops.

BOMMER'S MANURE.

We have just received a letter from Mr. CHARLES BAER, an agent for vending the paten for making manure by this system, who informs us that he will be in this city in the course of ten days, for the purpose of selling rights, when he will, for a slight additional compensation, go on to the plantation of any gentleman who may purchase a right, and instruct him, or his overseer, how to make the manure. Gentlemen desirous to purchase rights, or to avail themselves of his instructions, will please leave notices at this office.

WHITE PLAINS, Greene County, November 19, 1843.

To the Editors of the Southern Cultivator:

Gentlemen:—I some time since addressed you a letter in which I promised shortly to give you an account of my hogs, &c. I have been long waiting for the portrait of my boar Rip Van Winkle, to head said publication with. I have lately heard it was shipped from New York, and if not lost on the way, you will shortly hear from me again.

Not long since I saw an inquiry in your paper from a gentleman in Athens, relative to the barrenness of sows, &c., and asking your correspondents what to do with one to make her breed.

I was similarly situated with himself, and had adopted your recommendation, to wit: reducing her, but without any effect. Mine was an exceedingly fine Berkshire sow, purchased of Mr. C. N Bement, with a thorough knowledge that she did not or had not produced pigs, nor *been in pig*, although nearly three years old. She was regularly in season for the boars every 18 to 21 days, from November 6, 1842, to June, 1843, and was as *regularly* served by *different* boars, but to no *use* or *effect*. By the latter time I had reduced her quite poor; I then concluded to try experiments on her, and about 10th June, half spayed her, or, in other words, took out one of her prides. In July afterwards, (about 25th) I found her again in season for the boar, and put her in the pen to my imported boar Ontario, and I am pleased to say, she not only proved in pig, but on the 13th instant, produced me six fine pigs. I would also state that her condition was about the same it had been for several months, and the management the same, and she had on *former occasions* been served by the same boar. I would advise your correspondent to make the experiment, and hope he will meet with the same success. While writing, I will remark, that I am selling all the Berkshire pigs *I can raise* from *twenty sows*, and that I last Saturday sold to Mr. James M. Crook, of Benton county, Alabama, a lot of ten fine pigs. They consist of three boars and seven sows, and are of choice selections. Persons in that vicinity wishing to see *genuine Berkshires* can *now do so* by calling on Mr. Crook. Hoping that your subscription list for another year may receive

that encouragement which *it deserves*, and that every planter in Georgia will do his duty and remit you *his dollar*,

I remain, as ever, truly yours,

JOHN BONNER.

AN EXPERIMENT.—We had, says the Charleston Rambler, the gratification of being present on Friday, the 20th ult., at the breaking in and measuring of an acre of corn at "Geddes' Hall," the plantation of Capt. G. C. Geddes, of St. Andrews. It was cultivated as an experiment, as follows, on land exceedingly poor, and which would not, in the ordinary culture, produce more than 7 bushels per acre. The acre alluded to, was laid out in beds 5 feet apart, the seed planted in double rows, 20 inches apart diagonally—no manure was used before the seed was in the ground. When the corn was 5 or 6 inches out of the ground, it was manured with *live cotton seed*. As soon as the cotton seed began to sprout, it was hoed and turned under.—When the corn was a foot high, it was again fed on the surface with well-rotted manure, from the lower layer of the cow-pen, well saturated with ammonia. The basis of the manure used, was salt marsh and sedge. The single acre treated as above, produced 68 bushels.

In the Southern Transcript, published at Alexandria, La., we find an account of a pumpkin, raised by Smith W. Gordon, Esq., of the parish of Rapides, weighing 186 pounds.

EXPLANATION OF TERMS.

We give, says the Mississippi Valley Farmer, the following explanation of terms, for the benefit of our junior readers, and those young and inexperienced farmers who have not made themselves familiar with the technical terms in use among agricultural writers.

1. *Broadcast Husbandry*—is that in which the grain or seed is sown by a cast of the hand, so as to be strewed equally as possible over the whole ground.

2. *Drill Husbandry*—is that in which the grain or seed is sown in rows, by means of machines contrived for that purpose, and the ground afterwards kept stirred and cleared of weeds by a kind of plow called the horse-hoe, hence sometimes called the *horse-hoeing husbandry*.

3. *Convertible Husbandry*—is when the ground is cultivated alternately in tillage and grass.

This is much practised in some parts of the country, with wheat and clover. A field in clover, soon after haying, is turned up and sowed with wheat and clover seed. After the wheat is taken off, it is once mowed, when it is again plowed up and sowed as before; thus the ground carries wheat every other year, and the intermediate years clover. The term applies also to a succession of any kind of crops in which grass is comprehended as one.

4. *Trench Plowing*—is running the plow twice in the same furrow.

In doing this the top soil, with all its foul seeds, is cast to the bottom of the trench, and a new soil is thrown up, upon which the sun had never before shed its rays. It is done sometimes at one operation, by a plow constructed for the purpose, called a *trench plow*.

5. *Horizontal Plowing*—is so conducted, by the use of an instrument called "rafter level," as to lay the sides of hills in horizontal *beds*, about six feet wide, with deep hollows or water furrows between, for the purpose of retaining the rains.

6. *Indigenous Plants*—are such as are natives of the country in which they are found, or grow.

Thus, maize, the potatoe, and tobacco, are called indigenous to America, having first been found here, and from America introduced into Europe.

7. *Exotic Plants*—are such as are natives of foreign countries.

Such as the lemon tree, and many others, when introduced into the New England States, and cultivated in hot houses.

8. *Annual Plants*—are such as are of but one year's duration.

Such are most of our garden plants and all others growing from seed sown in the spring, which arrive at maturity in the summer or autumn following, producing flowers and ripe seed, and which afterwards perish both in their *top and roots*.

9. *Biennial Plants*—are such as, in their roots at least, are of two years duration.

Many of these plants perish in the *top* the first year, but live in their root through the winter, and the second year shoot up stalks, flower, produce seed, and afterwards perish both in root and branch. Such are the parsnep, carrot, &c.

10. *Perennial Plants*—are of many years duration.

Such are all plants, whether the leaves and stalks perish annually or not, provided the *roots are of many years duration*, as the horse-radish, burdock, &c.

11. *Herbaceous Plants*—are those whose herb, that is, whose stem and branches are of but one year's duration, whether the root be annual, biennial, or perennial.

12. *Esculent Plants*—are such as are replete with nutritious matter, consequently, proper for being eaten as food.

Such as parsneps, carrots, cabbage, beets, and various others of a similar nature.

13. *Umbelliferous Plants*—are all such as produce their flowers on the ends of numerous little flower stalks or rays, nearly equal in length, spreading from a common point or centre, forming a level, usually convex or globose surface, somewhat like a spread umbrella, as the parsnep, carrot, &c.

14. *Leguminous Plants*—are those of the pulse kind, which, producing their seed in pods, may be gathered by the hand, as peas, beans, &c.

15. *Culmiferous Plants*—are all such as have smooth pointed stems, and whose seeds are enclosed in chaffy husks or coverings.

All the grains, and most of the grasses, as well as many other plants, are of this kind.

16. *Deciduous Plants*—are all such plants, whether of the tree or shrub kind, as shed or loose their leaves in the autumnal or winter seasons.

17. *Tuberos Roots*—are such as consist of one or more knobbed tubes, of a solid, fleshy substance, as the potatoe, artichoke, &c.

18. *Bulbous Roots*—are such as have a roundish, swelling, bulbous form, composed of numerous scales or coats, as the onion, garlic, &c.

19. *Tap Roots*—are such as in the form of a tap descend down into the ground in a perpendicular direction, as the carrot, parsnep, red clover, &c.

20. *Fibrous Roots*—are such as are wholly composed of numerous thready or fibrous parts, such as the roots of all kinds of grain.

21. *Radicals* or *Radicles*—in botany, are the small fibrous roots, which extend themselves in every direction in the earth for the purpose of collecting nourishment for the support of the plant.

22. *Green Crops*—are such as continue green while ripening their seed, or till taken off the ground; such as beans, peas, cabbage, carrots, turneps, &c.

23. *White Crops*—are such as become bleached, or turn white and dry while ripening their seed; such are all the various kinds of grain.

All plants, while their leaves continue green, and especially such as have large leaves, draw much of their nourishment from the atmosphere. The *green crops*, therefore, exhaust the soil much less than the *white crops*, whose leaves becoming dry receive nothing from the atmosphere, but draw all their support from the soil while ripening their seed.

MODEL FARM.

The British Farmers' Magazine for January, 1843, contains the following account of a model farm, cultivated chiefly by boys who are pursuing a course of education in scientific agriculture:

"Perhaps the most successful example of the capabilities of land, under proper management, in Ireland, and of the immense crops which can be raised, may be seen on the National Model Farm, under the Board of Education, at Glansuevin, near Dublin. This farm, strictly conducted on the improved system of green cropping and house feeding, contains 52 statute acres, and there were on it, during the year, 22 head of cattle and three horses. It supplies on an average, ninety persons during the year with farm produce, such as milk, butter, potatoes and vegetables of various kinds! and furnishes the farming establishment with pork, besides a number of private families with the above articles. A considerable quantity of vegetables is carried to market, and all kinds of grain, which is abundant. There is at present a crop of oats upon the farm, the produce of 14½ British acres. It is secured in eight stacks, and is estimated by the best judges to be equal to the average produce of 50 acres. It stood pertectly close upon the ground, averaged 6 to 7½ feet in height, the head and ear corresponding; the other crops, potatoes, turneps, Italian rye grass, &c. of the like quality.

The manager conducts the farm on his own account; pays £256 7s. 8d. per annum for rent, besides other expenses, amounting in all to upwards of £400 per year; and we are informed, and believe, that he realizes a very handsome annual sum from it besides. He labors and manages it almost exclusively by a number of boys, agricultural pupils, and teachers, who are there in training in the science and practice of agriculture. As a test of what land is capable of producing, when brought to its highest point, there are few examples so appropriate as we have in this particular instance; more cattle kept and fed, more human beings supplied with the common necessaries of life, more manure accumulated, more employment given, and, in fact, more money made on this spot of land, than on any other farm of the same extent (conducted on a proper scientific rotation of grain and green crop,) in any part of the empire, or the world. Did the average land of Ireland produce only one half of the value, according to quantity, that is on this model farm, we should hear no more of corn laws, tariffs, or want of employment among the people.

EIGHT THINGS THAT DO NOT LOOK WELL.

It does not look well to let the garden grow up to weeds, and then say that a garden is good for nothing.

It does not look well to have the gate without hinges, held up in the gateway by a prop in a "slantindicular" position, leaving at the bottom an aperture through which some hog with a convenient nose can rub, and so slip around into the garden.

It does not look well for a man to thump and abuse his horses or oxen, just to try his whip; or to suffer his boys to do so.

It does not look well to keep the horse in a stable not cleaned, till his hind feet are 45 degrees higher than his fore feet, so that he is obliged to rear up to get himself on a level every time he wishes to swallow a little hay or oats.

It does not look well to have the woman hang out the clothes on rough and thorny bushes, and tear them in getting them off, when a neat line would save that trouble.

It does not look well for a man to keep six lank, hungry grey-hounds, when he can keep no cow or pig; and for no purpose but to worry the neighbors' cattle, and annoy the neighborhood with continual barking.

It does not look well for farmers' daughters to be always talking about piano playing and the trillings of Signor Cantanini; while they do not

know of what butter is made, and pretend to suppose a cow a rhinoceros.

It does not look well for any body's daughters to walk the streets in kid slippers in December, and lace themselves so cruelly that their voices waste away, and their cheeks turn to the color of moonlight.—*Prairie Farmer.*

ACID IN SOILS.—It has become mooted questions of late, whether there be acid in the soil? and if there be, whether lime will so neutralize it as to destroy *sorrel* and other sour vegetables? Some have affirmed that the doctrine which ascribes vegetable acid, or, as it is chemically termed, oxalic acid, as the cause of the growth of sorrel, is unsound; others, that sorrel cannot be destroyed by the application of lime. Now, for ourself, from our own experience, we are forced to believe, that there is truth both in the fact of the existence of the acid, and in the competency of lime, as a neutralizer, to remove it. Our reason for this opinion is a plain one and soon told. We had some years ago a lot of about two acres of sandy land, resting upon a clay bottom, so infested with sorrel as to destroy two successive crops of clover. The land had never been limed, and believing that the presence of the sorrel was owing to a superabundant supply of acid in the soil, we determined to try the effect in neutralizing it, and it so turned out that we had some *freshly burned, unslacked oyster shell lime on hand*, two hundred bushels of which we spread over the two acres of ground, on the top of the lay of sorrel, for it was several inches high; plowed both the lime and the sorrel in on the 20th of July, and on the 15th of August following, we gave the ground another plowing, returning the lime to the surface, which had become tolerably well slacked. We let the lot remain until the following spring, when we sowed it in oats and clover, and we were never again troubled with our old enemy the sorrel.—As there has been considerable discussion of late upon this subject, and no little diversity of opinion upon this matter, we have thought that it might be interesting to our readers to know the views entertained by that eminent chemist, Professor Dana, of Lowell, Massachusetts, whose admirable work upon agriculture, shows that *his* opinion is entitled to profound consideration. It has been alleged in support of the position, that lime will not destroy sorrel, that in many instances where lime had been applied to the soil, that the sorrel continued to grow, and even that in some instances it had grown through coatings of marl, which is mainly the carbonate of lime, or, to speak more plainly, lime in a slacked state. This, we think, is very plainly and satisfactorily accounted for by Professor Dana. His views are, that the lime should be plowed in, in an unslacked state, and not be left on the surface to become slacked by the elements; that the vegetable acid of the soil reaches much deeper than the minute portions of the lime which is dissolved by rain can penetrate; that if the slacking takes place by air alone, that, as carbonate of lime is insoluble, none of its active neutralizing principles can enter the soil, and, therefore, cannot effect the sorrel, unless, perhaps, by preparing it, through the vegetable matter which it may have caused to decompose, additional food, by which its capacity for sustaining life is increased rather than diminished. This is our reading of the Dr.'s communication, and as his *theory* corresponds with our own *practice*, we feel justified in commending his views to public notice.—*A. Farm.*

THE PRICE OF GLORY.—A writer in the last number of Blackwood estimates the numbers left dead on Napoleon's fields of battle at one million eight hundred and eleven thousand!

AUGUSTA MARKET.

TUESDAY, NOV. 21—P. M.

Cotton—Our market for the last two days has assumed a very quiet aspect, as both holders and buyers seem disposed to await the receipt of later accounts from Europe, which will be due here by to-morrow's mail. Prices, however, are very firm, and we quote 6 to 7¾c as extremes—principal sales 7 to 7¼c. Square bales are quite in demand, and generally command ¼c more than round of the same quality.

Dry Goods, Groceries, &c.—Our dealers are generally well supplied with heavy and well selected stocks of goods in their respecti e lines, and prices generally range very low for all staple articles.

Exchange—Sight checks are abundant on Savannah, Charleston and New York at par.—Central money is quite firm at 5 to 7 ℘ cent discount. We hear of no transactions in State Bonds, which are very firm and tending upward.

GARDEN AND FIELD SEED.

A GENERAL assortment of fresh and genuine GARDEN and FIELD SEED, among which are the following:

Red and White Clover,
Blue and Green Grass,
Rye and Orchard do.,
Timothy and Herds do.,
Millet and Lucerne do.,
Seed Corn of every valuable variety,
Seed Wheat,
Buckwheat and Potato Oats,

Kept constantly on hand by the subscriber, all of which are offered for sale at very moderate prices. All orders, by mail or otherwise, executed with neatness and despatch.

WM. HAINES, JR.,
No. 232 Broad street, Augusta, Ga.
August 30. 18–tf

TURNEP SEED.

A SUPPLY of the following varieties of fresh TURNEP SEED just received, viz:

Yellow Sweedish or Ruta Baga, very fine for stock,
Large Globe Turnep, } Fine
" White Flat do. } for
" Hanover or White Ruta Baga do } table
" Norfolk do. } use.

For sale in quantities to suit purchasers, by
Aug. 30 18–tf WM. HAINES, JR.

BOMMER'S PATENT MANURE.

THE undersigned is the Agent of Messrs. Abbett & Co., for vending rights to individuals for making and using the above named Manure. By reference to the following advertisement of Messrs. Abbett & Co., the prices may be ascertained. All orders addressed to me, *post paid*, at Sparta, Ga., will receive prompt attention.
Aug. 30. 18–tf R. S. HARDWICK.

THE BOMMER MANURE METHOD,

WHICH teaches how to make vegetable manure without the aid of live stock, in from 15 to 30 days, by a course of humid fermentation set into action at a cost of from 50 cts to $4.

And also to make Compost *in a few days*. And how to make a rich fertilizing liquid called "purin," having all the strength without the acrid qualities of urine.

With the view of graduating the cost to the quantity of land upon which it may be desired to use the method, the following scale of prices has been adopted, viz:

For Gardens of any extent $6
Farms up to 100 acres 10
" from 100 to 200 acres 15
" " 200 to 300 " 18
" " 300 to 400 " 20
" over 400 acres in any one farm 25

By the remittance of the sum here specified, a copy of the method will be sent by mail or in any other mode proposed by the purchaser.

All letters of inquiry must be post paid.
ABBETT & CO., Baltimore,
Proprietors of the patent right for the Southern and Western States. aug 16

THE SOUTHERN CULTIVATOR

IS PUBLISHED BY

J. W. & W. S. JONES,

And will be issued every other Wednesday, at ONE DOLLAR a year, INVARIABLY IN ADVANCE. The CASH SYSTEM will be rigidly adhered to, and in no case will the paper be sent unless the money accompanies the order.

ADVERTISEMENTS pertaining to agriculture will be inserted for ONE DOLLAR for every square of TWELVE lines, or less, for the first insertion, and SEVENTY-FIVE CENTS per square for each continuance.

☞POST MASTERS are authorized to receive and forward money free of postage.

☞ALL COMMUNICATIONS MUST BE POST PAID

SOUTHERN CULTIVATOR.

VOL. I. AUGUSTA, GA., DECEMBER 6, 1843. No. 25.

From the S. C. Temperance Advocate.

RUFFIN'S REMARKS ON THE INDIAN PEA,

And other Manuring Crops and Forage Crops.

To the Farmers' Society of Pendleton:

Gentlemen—When at your called meeting on the 26th inst., you requested me to deliver an address at your approaching annual meeting, I was compelled to decline the honorable service, by several considerations, which it is unnecessary to repeat. But though unwilling to attempt, at such short notice, and amidst other and uncertain calls of duty and business, to undertake so formal a matter as a regular *address*, it has occurred to me that possibly I may in some degree meet your wishes in another mode, in which the absence of all pretension to the dignity of form or manner, will at least serve to prevent that disappointment which would be produced by the performance falling below your too favorable and too high expectations. I will, therefore, hastily as my position and time compel, and in such plain manner as our recent personal conference was conducted, repeat in writing, or enlarge upon, and endeavor to more strongly impress some of the subjects of my then verbal remarks—and also, present some other cursory views which seem applicable to your own agricultural position and circumstances.

Among the great and peculiar blessings of South Carolina, are the two important products, or rather the capacity of climate and soil, for producing them, the sweet potato and the many varieties of the Indian or field pea. And although both these crops are cultvated on almost every plantation in the State, and generally to great extent, and though one or both are used largely every where to furnish food to man and beast—still I venture to assert that the value of these products have not been yet fully appreciated by one of their cultivators. As the sweet potato belongs less to your neighborhood than to the lower country, I will pass it by, with no further remark than that I deem it a far more valuable root crop than any other produced in the United States; and that even on plantations where there is the most use made of this root, its value will not be fully availed of, while there shall exist any scarcity of those dairy and live stock products, which are elsewhere obtained from much less nutritious roots, as turneps, beets, carrots, Irish potatoes, &c.

For the pea crop, the climate and soil of this region may perhaps be also somewhat less propitious than those of the lower country. But no where else have I met with better growths of peas than I have seen recently here; and no where such modes of raising the crop, (though but in few cases,) to serve for hay or for manure to the land—and of which peculiar and as yet very limited practices, I wish to induce your adoption and extensive use.

The almost universal mode of raising the pea crop in South Carolina is by planting among corn. The length of the summer permits this planting to be done after the corn is well advanced in growth, and for the peas to have time to perfect their growth after that of the corn has ceased. Universal experience seems to have confirmed the value and profit of the pea crop thus made. But this mode, however advantageous, seems to me of far less benefit, than either of several other modes. Of one of these I have myself had large and satisfactory experience, under a less favorable climate—and others I have but just seen in this neighborhood, or elsewhere in this State.

Whatever may be the amount of product, or of profit, from raising peas among corn, as a secondary cultivated crop, it is attended with much trouble in the planting, and separate tillage.

Peas, (like red clover, which is also a plant of the pea tribe,) draw sustenance very largely from the atmosphere, by their system of broad leaves, compared to what they draw from the soil. Hence such plants take less from the land, and return more to it, than any others, and therefore are the best of manuring or meliorating crops, to be alternated with the more exhausting grain and tillage crops. In this respect, red clover has stood unrivalled, because in the more northern and improved lands, where its admirable manuring and cleansing qualities have been fully experienced, peas cannot be as well raised. From some trials made here, there is good reason to hope that red clover may be raised to great advantage, even without lime, the application of which would ensure its perfect success. But, even if this were not so, the pea crop sown broadcast is scarcely less valuable than clover as a manuring crop, and superior to it in several other respects. And the great ground of recommendation of the pea crop, is that it may be introduced after either of several different grain crops, and to fill longer or shorter intervals of time, which would otherwise be fruitless for melioration, or serve to fill the land with foul weeds and depredating insects. In this manner, peas may be advantageously used to improve and add to any scheme of rotation of crops—lessening the exhausting operation and destructive effects of the worst rotations—or making one really improving and excellent, which, without the addition of peas, would be more exhausting than meliorating.

The principal experience which I have had of peas as a manuring and cleansing crop in my own practice, was the sowing the field broadcast, upon a good and clean plowing, and harrowing in the seed, (of the cow pea, or some other variety producing much vine and leaf,) about 1½ bushels to the acre. The crop at or near maturity of the more forward pods, should be well plowed under about a month before the time to sow wheat. The wheat should be sown on the same furrow, and covered by the harrow. This is an admirable preparation, serving by the thickly covering and shading and smothering and subsequently killing of the peas, well to cleanse and also to manure the land, and to produce a much better crop of wheat than can possibly follow corn, cotton, and still more wheat itself or other broadcast grain. The sole objection to this preparation is the cost of the plowing for the pea seeding; and this perhaps may be often saved by a new practice of which I have recently learned something elsewhere.—The black pea, and also a dark red pea, will lie upon the ground, or remain covered therein, through winter without rotting, and will germinate and grow in the spring. Availing of this property, these peas have been successfully sown both late in autumn, (or early part of winter,) with wheat, and in spring with oats. The peas grow but little until the grain crop is removed, and then grow rapidly, and soon form a good cover. It is not to be supposed that this plan will always succeed. But it has done well, on a small scale of operations, for three years, as conducted by Wm. R. Davis, Esq., in Fairfield, and for six years on a larger scale, by Maj. J. Littlejohn in Union.

If it be not desired to use the broadcast pea crop to prepare for and manure for wheat—or if it be preferred to save the crop for hay—then the latter may be done, as I had the benefit of seeing but a few days ago, on the neighboring plantation of one of your Society, the Hon. J. C. Calhoun. The crop of peas was mowed by the scythe; and after lying a few hours in the sun, and without being turned, the vines were put up in high and narrow cocks around a stake 5 or 6 feet high, to stand until cured enough to be stored in the house. This plan (which, by the way, with smaller cocks, is the best mode I have ever known of curing all kinds of grass for hay,) saves the trouble of turning the hay with forks, and the loss by such turning, causing the dropping of the leaves and shedding the ripe peas, as well as too much sunning the hay.—The provender thus saved is excellent, and the land is left clean for any succeeding crop. In this case, the cow pea was the variety used, and the sowing was in May, at the rate of two and a half bushels to the acre.*

A still more admirable plan of raising peas I saw on part of the same plantation. The seed had been sown broadcast (one bushel to the acre) in the corn land at the last plowing, which was in July. The crop of corn we suppose may be 25 bushels to the acre; and the peas (as seen on the 26th of Sept.) formed a thick and rank cover of the whole ground.

I will now suggest the application of what appear to be the advantages offered by the pea crop, to the increase of the general improvement to be attained from rotation, or alternate cropping.

The great benefits to be attained from a proper system of rotation of crops, including rest to the land, or of manuring crops alternating with the exhausting, would seem scarcely to be known in South Carolina, as nearly all existing practice is in opposition to, or disregard of, the principles of rotation. In the lower and middle districts, where cotton and corn are the great and all important crops, and where there is scarcely any broadcast crops, there is also scarcely anything like rotation practised. In the upper districts *bordering* on the mountains, and where cotton ceases to be a principal crop, and wheat (or oats) becomes so, there is in use an imper-

*It was not until after this communication had been sent to the President of the Society, that I saw another mode of harvesting pea hay, which is still more safe than that described above, though requiring more labor. Stack poles 12 to 15 feet long, and about 4 inches in diameter at the larger end, are set firmly in the ground, where wanted. At about 4 and also 8 feet from the ground, the pole has an auger hole, 2 inches in diameter, bored through, and a strong, round stick, five feet long, passed through each hole. The pea-vines are pulled up, or cut, when there is no moisture remaining on them from rain or dew, and after lying part of a day, or otherwise immediately after being cut, (according to weather and other circumstances,) the vines are stacked around the pole There ought to be some open rubbish on the ground as a foundation; but even this is rarely provided. The stack ought to be 5 feet in diameter, until near the top, when it is brought to a point, and a slight cap of straw put on, if designed to stand long. The sticks serve to admit air, and to prevent too much of the weight of the stack pressing on the lower part. The provender is thus well cured and entirely saved. This method was first introduced in this neighborhood by Mr. Thomas M. Sloan, who has practised it successfully for eight years.

fect kind of rotation, but which is the result not of reasoning and design, but of necessity. For the wheat, or oats, demanding a preparatory cleansing culture, *must*, if raised here at all, follow corn. And as wheat and oats are taken off the land early in summer, the field *must* have rest from a tillage or exhausting crop the remainder of that growing season. And if the wheat and oat ground be not separate from the other land in tillage, the weeds and natural grass, which rapidly cover the land after the grain has been removed, *must* be left ungraved, and thus be permitted to die upon and manure the land slightly, before the next succeeding year's crop of corn shall begin again the short round of exhaustion. Now whether the practice be this very simple and very scourging two shift rotation—or of three shifts, by adding a third year of rest—or of any longer and still better successions of crops—the pea crop may be added thereto, even without any other change, so as to serve admirably well to mitigate the severity o the most exhausting course, or to increase the manuring effects of the most lenient and meliorating. Thus, in the year of rest, if there be one, a good broadcast pea crop may be substituted for the less rich and less dense growth of weeds and scanty grasses. After reaping the wheat or oat crop, peas may be immediately sown, if not obtained by previous sowing with the grain, as above referred to. And with the last plowing of every corn crop, peas may be again sown broadcast, and (if succeeding as well as this year at Fort Hill,) a fine secondary crop obtained for the single cost of the seed and the labor of casting them. Nor would it be necessary that all these intervening pea crops should be applied as manure. Perhaps one of them given wholly to the land in three or four, or even five years, might suffice for fertilization, and the other pea crop be in part or in whole mowed and cured, for hay or winter forage, or otherwise consumed on the land by fattening cattle and hogs.

In addition to the highly valuable manuring and cleansing qualities of the pea crop, it has another important value in any rotation, presented in the complete *change of condition* which it makes in land previously under either cotton, corn, wheat or oats. In such change of condition consists, in my opinion, the greatest benefit of a system of rotation. On this particular head some remarks and new views will be offered, though I shall not discuss generally the ample subject of the theory of rotation, nor present, either as approving or to oppose, any other and more generally received reasons for the practice of rotation.

I deem that a change and succession, or rotation of several different crops, is beneficial mainly in two modes, as follows:

1st. Because one crop, by its necessary and peculiar tillage and management, serves to prepare the land for the reception of another of different kind, and requiring different tillage.—Thus, corn, cotton or tobacco, all requiring after tillage, are not hurt, but on the contrary are improved, by being grown on land foul with the weeds, &c., or a previous growth, and on which and with no better preparation, wheat or oats could not thrive. And these crops, therefore, require to follow either of the former tillage and cleansing crops. By such following of either corn, cotton or tobacco, by wheat, oats or rye, it is obvious that both must fare better than to reverse the order, or to let any one crop be kept for successive years on the same field, or to be attended only with other crops of similar tillage and similar character and habits.

2d. The many disasters which in so many ways sometimes injure all cultivated crops, I suppose to be mainly caused by insects; of which many kinds of the most injurious may be so minute in size as to escape observation. Now every crop and plant has its particular tribes of parasites, or depredating insects or animalcules, which if not confined by their natural wants to that particular growth, or to its near kindred plants, for sustenance and for shelter, cannot thrive on other different plants, and be sheltered in other very different conditions of the land. Thus, if any one crop, and of course one kind of condition of the ground, be continued through many years—whether of wheat or corn or cotton—it may be safely inferred that the tribes of depredators of which the sustenance and shelter are more favored by such crop and its tillage, will continue to increase generally from year to year, and to become more and more destructive in their ravages. Other circumstances, as of weather, &c., when favorable, will still more favor such increase, and if unfavorable, will obstruct and perhaps conceal the injury, still inflicted however, in a less degree. But with such variations, and on a general average of years, crops of the like kind continued year after year, and the land kept in like condition, must serve to render the crops more and more diseased and unproductive, even though no actual decrease of fertility of the soil be suffered. Now, instead of this, suppose every year, or even sometimes oftener, there shall occur as complete a change of crop and of condition of the land, as the interposition of a broadcast and dense cover of peas, between each two tillage or grain crops. It is scarcely possible to conceive a greater change; and it is very improbable that the myriads of insects which had been sustained and kept increasing on any one crop, whether of corn, cotton or wheat, can thrive or even live after such great change of circumstances.

I shall not presume to propose for this region any particular scheme of rotation as the best. To decide such a question is always extremely difficult for the most experienced and enlightened cultivator, for himself and in the place of all his foregone labors and observations. And far less qualified would any person be to prescribe a precise plan of rotation, in a region and for circumstances very different from those to which he had been accustomed. But if the above general views are sound, they may be easily and beneficially applied to practice, and in various modes. I will merely add, that the power, however, of introducing the pea crop in so many ways, and for the several different products of peas, green food, hay, or manure, offers facilities here for rotations more perfect in operation, or more in conformity with reason and theory, than any known to me in practice elsewhere.

In the use of green crops as a manure, it is a common error of new beginners to make the attempt on poor land. The green (or dry) manure crop for the poorest land, should be merely its own natural growth of weeds, permitted to die and fall and decay on the ground, and this to be interposed as often as may be between the tillage and exhausting crops. This manure of weeds, if of less amount and value than an artificial manure crop, as peas, at least costs nothing for seed, preparation or tillage. To obtain profitable returns from peas or clover, the land should be able to bring at least a moderate growth. For very nearly the same cost of seed and plowing would be incurred by having such green crops, or either of two pieces of ground, of which the one would yield four times as much growth, and consequently effect four times as much manuring and improvement as the other.

Though the pea crop is very valuable for dry forage, making indeed an excellent hay, it by no means follows that grasses for hay should be neglected, as they are here, and which neglect is a most deserved opprobrium of the Agriculture of South Carolina in general. I will not enter upon the copious and important subject of grass husbandry and its products, so much needed in this State, and yet so easily at command. One particular crop and practice will only be referred to, because well known to all now present. This is seen in the meadow of C. C. Pinckney, Esq., near the village of Pendleton. The growth is the Rice grass, (*Cersia orizoides,*) which is a native and a very productive and valuable grass for hay, and which, as Mr. Pinckney's meadow shows, may be produced in abundance in every bottom having a stream running through, by means of a very simple and cheap mode of irrigation. This grass thrives best in this southern climate, and may be obtained in every piece of suitable ground by merely causing the stream to flow or trickle slowly over the surface. It is not referred to as the best grass for culture and product, but as one easily obtained, and at small expense. I have known it in my own wet meadow ground for 30 years, and highly appreciate its peculiar productiveness and good qualities for hay. But I had not learned how to give it entire possession of the ground, as is done by Mr. Pinckney, nor is its growth in Virginia by any means equal in size to that which is seen in South Carolina.

The management and maintenance of good meadow land, for hay, are cheaper than those of even the poorest lane under tillage crops; and the net product of hay is not surpassed by any but the richest of tillage crops. Yet no kind of agricultural product, essentially necessary for ordinary consumption, is so much neglected.—Hundreds of thousands of dollars are every year paid for New England hay, imported into Charleston and Savannah, and consumed in localities where the greatest labor of the cultivators are employed to keep down the exuberant growth of grass. And in these same localities, which are peculiarly and admirably suited for profitable dairy and other live stock products, all such products are scarce, mean and at very high prices.

These latter observations apply much more to the sea board than to this region. But there is very little more attention paid here to grass husbandry; and if the scarcity of products be less than in and near the cities on the sea board, it is only because there is less demand for them, and less consumption to produce scarcity.

Most planters do not feel the necessity, nor understand the propriety, of working hay crops, because, as they say, they now make enough long forage for their stock, and if they were to make hay, they would have no market for it.—Hay ought not to be sold at all from ordinary plantations; and in no cases except of excessive and disproportioned production, owing to very extensive and rich meadow grounds, or of great demand and high price for hay, as in the neighborhood of towns, together with the facility of obtaining purchased manures in return. In ordinary cases the planter who makes hay will be himself the most profitable consumer of it, if using it properly. And, perhaps, those who think that they have and consume enough forage for their stock, from their present corn fodder and other offal of grain crops, might find it still better to add thereto the hay from a few acres of meadow. But even if there be no deficiency of food requiring such addition, and there were 50 acres of good meadow added to a plantation of 500 acres of arable land, all this new product of grass might be profitably reaped and consumed on the plantation. And before increasing the stock products by the use of these new resources for feeding and fattening animals, an earlier and most advantageous use may be made of hay by every planter, and to a large amount, by substituting it for the corn fodder which is now universally gathered, and which laborious and injurious process might then be dispensed with altogether. I am sensible that my thus denouncing a practice which is almost universally approved and in use, and in my own country no less than yours, will appear to many as an agricultural heresy, not only unsustained by plausibility, but even absurd and ridiculous. Yet I am well assured, and by experience as well as by theory and reasoning, that the gathering of green corn blades, or cutting off the tops, for fodder, is always injurious to the grain; and that the loss in the value of the grain added to the cost of labor, and risk of securing the crops of fodder, together greatly exceed the whole value of the fodder usually saved. It would perhaps require more time and space than all these remarks should occupy, for me to present to you at full length all the grounds for this opin-

ion; and, therefore, I will add but a few remarks to the assertion of the general proposition.

In your own neighborhood, genetlemen, I have had presented to me a new evidence of the truth of my views in this respect. In observing the novel process of making sugar from corn-stalks, as conducted on a small scale by Major George Seaborn, I noticed the obviously much larger quantity of saccharine juice, and its greater concentration, or degree of sweetness, in the stalks from which the ears had been taken off as soon as they had shot out, compared to those which had been permitted to form grain. This difference, it is manifest, is owing to the greater part of the sugar, in the latter cause, and as nature designs always, having passed into the grain, and where it is converted to starch.—And this alone would show that the saccharine juice of the stalk is needed to form and perfect the grain. But where the ears have remained to grow, and at the latest time of growth of the corn for gathering fodder, (the leaves still being mostly green,) and the grain firm and almost hard, there will be yet remaining in the pith of the stalk a large quantity of saccharine juice. Every particle of the juice is destined to the better filling of the grain, and will be so used if the life of the plant is not cut short. But, when in this state, (nay, often much earlier than at this period of growth,) the leaves are stript, and the top cut, the plant immediately dies, and all subsequent conversion of the sugar then in the stalk to grain is effectually prevented. The grain of such corn is more or less shrivelled, and lighter by several pounds in the bushel than the grain from which the fodder has not been removed. As long as a blade is green, it is acting to sustain the life of the plant and to help to increase the bulk and weight of the grain.

But, putting aside this great and all important objection to the usual mode of saving fodder, there are other conditions which alone ought to serve to induce the substitution of hay, whenever it is practicable. Perhaps not one of you, gentlemen, has ever taken account of all the labor and cost of securing a crop of corn fodder, and comparing it with the value of the crop so secured. Neither have I. But if such estimates were made accurately, and in sufficient number to present a fair average of crops and of seasons, I think it would be found that the general cost would not fall much short of the product, and perhaps might exceed the whole returns. Besides the necessary labor in good corn and in good weather, which far exceeds that of hay-making, there is great risk of a spell of rainy weather occurring during the season (mostly in September) for this harvest; and every rain causes much trouble, and much rain produces great and inevitable loss of the partially cured fodder. Again—this is precisely the season most dangerous to health wherever malaria is at all to be feared, and no kind of plantation labor is so likely to affect health injuriously, as the gathering and securing of fodder. Even in fine, clear weather, the high and rank grass (or peas) among the corn, and the corn blades, are wet with dew, early in the day, and again before night, and the laborers are thus necessarily made wet. And the crispness of the cured (and sun-burnt) fodder, often forbids its being handled in the day time, and requires the night air to prevent great loss in the moving and stacking. This makes much of the work necessary to be performed at night, and which is an injurious or hazardous exposure of the laborers, both because of the night air, and the dew deposited on the high grass.—If any one accustomed to and contented with this slow and tedious and altogether uninteresting portion of plantation labor, could but once compare it experimentally with the rapid, safe, enlivening and delightful operations of hay making, his sensations would as strongly urge the substitution of the former by the latter, as ought to be done by sound calculation of profit and loss EDMUND RUFFIN.

Pendleton, September 28, 1843.

THOMAS AFFLECK'S PROPOSITION.

For a premium of Plate to be awarded to the Planter who raises the most Cotton on a given piece of land.

To the Editors of the Concordia Intelligencer:

GENTLEMEN—I make this proposition with much diffidence, being but a young planter—but, I can safely say, *one anxious to improve and learn.* I have sought every means of acquiring information, and particularly, by conversation with experienced planters. I have visited many plantations noted for being well managed; and the conclusion I have come to, is, that there are few, very few, planters, whose system and practice could not be very materially improved upon.

To convince all of this, let those who think their system already perfect, and that their management of the cotton crop is the best and most profitable, and who have confidence in its results, join me in what I have to propose.

Many, I presume, of those present, have either seen or heard of the communication made to the Albany "Cultivator," in December last, by Dr. Cloud, of Alabama. Dr. Cloud states, that by pursuing a proper system of rotations of crops, by a careful selection of his seed, by manuring high, and by giving additional distance to the plant, he was enabled to gather 5,989 lbs. per acre, of seed cotton. This, all will say, is an enormous yield—and most assuredly it is so. Yet I, for one, have little doubt but it can be reached here—not, however, without making the attempt. Although I fear that I shall never be able to reach so high a mark, I will never rest satisfied until I have come as near it as I can.

If we could, upon our hill lands, produce even 2,000 lbs per acre, by adopting a reasonably improving system, and by almost any extent of manuring, would we not be immensely benefitted? How many planters, cultivating hill lands, gather over 700 lbs per acre? Not many. And yet, to do even this, requires incessant hard work from New Year's-day until Christmas.—The difference between plowing, planting, tending and picking over, say 300 acres, and 100 is very great, and would allow of much labor being bestowed in making and applying manure, and in extra-deep plowing. Nor need I descant upon the comfort, and advantage to the planter, of being able to plant and tend as much ground with one half of his hands, as the whole of them can pick clean by Christmas—leaving him the other half of his force for the rest of the work necessary on a farm—including, of course, under such a system, manure-making.

How it would astonish the farmers in my native country, to be told, that at this late day of agricultural improvement, their brethren in every part of America, and particularly amongst the travelled and enlightened Southern planters, it required a lengthy argument to prove to them the value of deep plowing and abundant manuring!

Soon after reading Dr. Cloud's communication, last Spring, I had a piece of tolerably good hill land, containing three acres, three rods and thirty-five poles, cleared of the previous year's trash—some 200 bushels of manure per acre added, consisting of the scrapings of the cow-pen, partly decayed cotton seed and so on. This I scattered broad-cast, then threw up ridges, which average from centre to centre 5 feet four inches, were then harrowed down by running a heavy harrow lengthwise of the ridge. Here I planted some very superior Gulf-hill seed, presented to me by Mr. Compton, Sen., near Rodney. The seed I first dampened pretty well with brine, and then rolled in dry ashes—dropping some ten or fifteen seeds at about every 26 inches, which were afterwards thinned out to a single plant.

I am not certain of the amount of labor bestowed upon this piece of ground—the tending the same as that given to the rest of the crop; further than that my overseer, Mr. Ventriss, has repeatedly said to me, that he had not one half the trouble with the grass on that piece, that he had with any other part of the plantation—"that the grass did not trouble him there." I rather think that it did trouble some of us this year! This was, of course, to be ascribed to the deep ploughing.

Now, gentlemen, from the (scant) four acres of ground, Mr. Ventriss assures me, that he has already picked 7,325 lbs of superior seed cotton—and that there is yet cotton enough open, and to open, to yield over 2,000 lbs more. I know that he has been very particular both in picking and weighing, and have every reason to believe his report to be correct.

Now here we have, on a first hurried experiment, 9,325 lbs of seed cotton from (scant) four acres of ground—or, allowing 1,330 lbs to make a bale, (and as it is a very fine article, I think it a fair allowance,) we have seven bales of ginned cotton!

I leave it to yourselves to draw your own conclusions, as to the amount of time, labor and manure that one hand could very easily afford to bestow upon such a small tract of land, to produce such a result! It required at least 12 acres of the same land immediately adjoining, treated, planted and tended in the usual way, to yield as much cotton—and the staple is, to my eye, not nearly as good.

What I have to propose, gentlemen, is this: Let all who are willing to put to the test of experiment, a rotation of crops, deep plowing, a sufficiency of manure, choice seed, and additional distance to the plant, give in their names, and pay over five dollars to the Treasurer of this Society, (Adams Co. Agricultural Society,) the whole sum thus paid, to be, by him, and the President, laid out in the purchase of a piece of silver plate, which they shall award to the planter, so subscribing, who shall during the next season, give the necessary proof that he has picked and ginned the greatest quantity of good clean cotton, from five acres of land, planted and tended in such manner as he may have seen fit—tendering along with such proof, a clear statement of the entire process in writing, which each competitor binds himself to do when he enters for the sweepstakes. The proof requisite may be determined upon by a majority of those agreeing to compete. Those wishing to become competitors may either address W. J. Minor, Esq., President of the Adams Co. Agricultural Society; Wm. J. Ferguson, Esq., Treasurer, or myself, either through the columns of the South Western Farmer, at Raymond, or by mail post-paid. I have already fair assurance that the purse will amount to between fifty and a hundred dollars, and can see no reason why we may not have fifty entries.

November 18, 1843.

RECEIPT FOR CURING HAMS.—We have been handed the following receipt for curing hams by one of the most eminent practitioners in this city; the saleratus is at least new to us, and we therefore publish it, although it may not be a new ingredient in the receipt to others. In Cincinnati, where large quantities of hams are annually cured, pepper, allspice, cloves, nutmeg, cinnamon, and other little ingredients are usually added; but to the receipt.

Cover the bottom of the cask with coarse salt, lay on the hams with the smooth or skin side down, sprinkle over fine salt, then another layer of hams, and so continue until the cask is full. This ought to be of the larger kind. A cask holding 64 gallons is small enough, and it would be better if it held 120 gallons. Make a brine in the following proportions: 6 gallons water, 9 lbs. salt, 4 lbs. brown sugar, 3 oz. saltpetre, 1 oz. saleratus. Scald and scum, and when cold pour the brine into the cask until the hams are completely covered. The hams should remain in this pickle at least three months, and a little longer time would do them no harm.—*American Farmer.*

RECIPE FOR MAKING CISTERN CEMENT.—Ashes two parts, three parts clay, one part sand, mixed with oil, will make a cement as hard as marble, and impenetrable by water forever.

From the American Farmer.

VERY IMPORTANT TO FARMERS.

A new edition improved and greatly enlarged, of the Bommer Manure Method, secured by United States letters patent.

AGRICULTURISTS, although you have favorably received the first edition of my method, and though, as it appears from numerous testimonials in the agricultural papers, it has given satisfactory results, I have nevertheless seen that the first edition was too incomplete, and that from the numerous questions which have been addressed to me by subscribers, I have, like them, felt the want of a commentary upon the instructions, and clear and precise explanations upon various points of the application of the system, so that it may be better comprehended and more easily put into practice.

I have written a new work which is more complete, and which, I hope, will meet with their approbation.

It does not become me to judge of the merits of this new edition; nevertheless, I think that I can give the assurance that, in this work, the system is so improved, and its application rendered so easy, that the least intelligent farmer, if faithfully conforming to the prescriptions and instructions therein contained, cannot fail of success in his operations.

This work resting upon facts and practical results, which are conscientiously reported, is presented to you with confidence. Try and judge.

The work is divided into two parts. The first contains the method in all its simplicity.

The second contains explanations and analytical developments of the system; instructions upon its application; some new processes; solution of manure questions of high importance; and lastly, supplementary articles consequent upon the system.

To give you an idea of the new edition, I will cite part of its contents. The first part of the method contains—

1st. Two different processes, by means of which any one can cause, in a few days, the decomposition of all straw and green or dry vegetables, and their conversion into a rich, unctuous and durable manure.

2nd. Two processes, one by high fermentation, and the other by moderated fermentation, by means of which any one can reduce all kinds of turfy or swampy matter into a rich vegetable compost or mold.

3rd. A process, without fermentation, to reduce all kinds of swampy matter, pond mud, slime from rivers or the sea shore, street mud, black earth from the woods, &c., into a superior mineral compost.

4th. Two processes for preparing compost with earth.

5th. The means to augment and ameliorate manure heaps.

6th. The means to prepare "purin," a fertilizing liquid for irrigation.

7th. The employment of dregs or lees, residues of manufactories.

8th. A process for reviving the heat under garden beds, without changing the litter.

These various operations are represented by nine designs, each occupying its respective place in the work.

SECOND PART—FIRST SECTION.

1st. Vegetables compared with animal manure.

2d. Four principal advantages of the Bommer manure over that of cattle.

3d. A dissertation upon fermentation, the gravest question upon the subject of manure.

4th. Opinion of authors upon the question, "Should manures be fermented or not?"

5th. My opinion upon the question.

6th. Appropriation of my manure to different earths.

7th. Appropriation of my manure to various plants.

8th. Solution of the problem put by Payen, the celebrated chemist. He says "that the art of manures consists in the avoidance of the too great solubility of materials which decompose too easily, and to render soluble those which decompose with too much difficulty."

9th. The nourishment of plants, and of what they are composed.

10th. Vegetable metempsychosis, or transmutation of a dead into a living vegetable.

11th. Economy—how to cause it.

SECOND SECTION.

1st. Four different qualities of saturated water.

2d. The disposal of the place of operations in different ways.

3d. Ley ingredients; means of procuring them without expense; their fertilizing value.

4th; Retrenchment of three ingredients which are not absolutely necessary in the ley.

5th. Employment of ground bones, horn shavings, saw dust, ground charcoal, blood and other residues of butcheries and salting establishments.

6th. Table for reduction or augmentation of the ley ingredients, so as to appropriate the manure to the soil and plants.

7th. Variations of the quantity of the ley ingredients, according to the size of the heap.

8th. The least and greatest quantity of materials which can be employed in the fabrication of Bommer manure.

9th. Virtue of the ley—what it is.

10th. A simple process to render manure as short as you wish.

11th. How to reduce leaves to manure.

12th. Reasons why the heap ought to be covered with straw or hay, and not with solid or compost materials.

SECTION THIRD.

1st. Proportion to observe in the mixtures of turfy or swampy materials with vegetables, and why.

2d. The most favorable season for the preparation of composts after this method.

3d. Is it advantageous to use composts in a fresh state?

4th. Regulations to observe in the manufacture of composts.

5th. European composts compared, or mould compared with mine.

6th. Poudrette compared with my composts.

7th. Means considerably to augment the manures of a farm.

8th. Immense advantages of the employment of human excrements and animal dejections.

9th. Effect of watering with "purin" or manure liquor, urionus, putrified water, compared to that of my mineral or earth composts.

10th. Liquid manures compared with my composts.

11th. Enumeration of 24 principal advantages of this method.

SECTION FOUR—SUPPLEMENTARY ARTICLES.

1st. Analyses of earths; simple measures to detect the nature of earths without the aid of chemistry.

2 l. Advantage resulting from this analysis.

3d. Interest which every one has in knowing the nature of his lands.

4th. Means to detect marl.

5th. Division of manures; mode in use compared with that which I propose.

7th. This method is already in use on a great many farms; results which have been obtained from it.

The matter of the new edition occupies about 100 pages; it will be henceforth furnished to subscribers instead of the abridged method, which contained but 20 pages. The price of the patent right is definitely fixed as follows:

Farm with garden, not over	20	acres,		$ 6
"	"	"	100	" 10
"	"	"	200	" 16
"	"	"	300	" 18
"	"	"	400	" 20
Over 400 acres in any one farm,				25

The method cannot be taken for only a portion of a farm, and every subscriber is required to declare the whole extent of his arable land.

By the necessary documents recorded in the Patent Office, the right for the Southern and Western States is held by *Abbett & Co.*, of Baltimore, and for the Northern and Eastern States, viz: New England, New York, New Jersey, Pennsylvania and Delaware, by *Geo. Bommer*, of New York, who keeps his office at 75 Greenwich street. Farmers living in the Northern States who desire to buy the true method are invited to send to my office or my agent. The only agents established by me, and who are authorized to sell my patented method, are Messrs. *Eli Barnet*, at Westville, Connecticut, general agent for the New England States, and *H. D. Robinson* at New Brunswick, New Jersey, principal agent for the State of New Jersey.

All agents hereafter appointed will be announced in the newspapers of the respective counties and States. Principal agents who may appoint sub-agents are bound to give notice to the agricultural public through the press.—Whenever this announcement is not made, the farmer should be on his guard not to be duped by counterfeiters, (who have already arrived,) and who will not fail to offer them false methods for their good money.

To facilitate the circulation of my method, a register is opened with each postmaster, where farmers, who have the intention to buy it, can subscribe. These postmasters will address every month a list of subscribers to my office, or to my principal agents in the respective States. The postmasters will receive, in the course of the next month, instructions for their guidance under the circumstances.

Every subscriber who, having paid the price, should not receive the method in due time, will please notify me of the delay, (at 75 Greenwich street, N. Y.,) when it will be immediately attended to.

Farmers, take notice that *Mr. Heermance, of Kinderhook, is not my agent.*

In order to prevent the frauds and to counteract the manœuvres of some rapacious individuals, always ready to invade the rights of others, I will serve them up to the agricultural public as they present themselves; and in this, I count upon the support of the press, who are also interested in denouncing to the public those who meditate injustice to them.

Finally, it should be known that all copies of the method for the northern and eastern States are signed and sealed by myself, and those of the southern and western States by Abbett & Co.; that any method embodying our instructions, which should be circulated under any other name, will be considered as false and counterfeit, and that those who make use of it will be prosecuted according to law.

Those who desire to buy the right for a State, or for one or two counties within my limits, can address me at my office, or my principal agents in the different States.

All editors of newspapers who have more than 400 farmer subscribers, by inserting the present article entire, and accompanying it by a small editorial article, shall have a right with a copy of the method, to its fullest extent, with the privilege of ceding the right to any of his friends, if he should not himself be a farmer.—To be entitled to the above privilege, he will address to my office the journal which contains the insertion in question, and the method will be immediately forwarded. If the editor intend to cede his method to another person, he should inform me, post paid, and send me the name and residence of the person to whom he wishes to cede it.

GEO. BOMMER.

The starch factory in Mercer manufactured about 140,000 pounds of an excellent quality last winter, grinding about 16,000 bushels of potatoes. We learn that they have made arrangements to grind 24,000 bushels of potatoes the coming winter, which will produce more than 240,000 pounds of starch. They sell the commodity in Boston for about $4 per hundred. This starch is used by the New England manufacturers for bleaching, in preference to that imported from Poland.—*Stockbridge Visitor.*

From the Southern Shield.

BARBOUR COUNTY AGRICULTURAL SOCIETY.

A meeting of the Agricultural Society of Barbour county, was held on Wednesday, the 22d of November, in the Baptist church; the President, Col. McDonald, in the chair. An eloquent and interesting address, abounding in valuable agricultural information, was delivered by Col. John L. Hunter. At the request of the President, the chair was then taken by Gen. Shorter, and Col. McDonald read the following

REPORT:

To the Members of the Barbour County Agricultural Society:

Gentlemen:—On the first of April last, I received through the Post Office, from the Hon. D. H. Lewis, Member of Congress from this district, the following seeds, directed to the President of the Barbour county Agricultural Society:

The English Dwarf Pea, Tobacco Seed, from Trinidad, the Alverado Wheat, the Blue Stem Wheat, and the Potatoe Oat. Owing to the small quantity of each kind of seed, and there being no meeting of the Society until June, I determined that the object of the donor would be more certainly carried out by sowing the seed and turning over the amount gathered to the Society, than by keeping them until a meeting took place and dividing them. Consequently on the first day of April I carefully sowed them in my garden in drills. I had some fears at the time, that the wheat might be injured by the frost, owing to its being sowed so late in the season, but as I might succeed in raising a small quantity of seed for each member, I thought it best to risk the sowing.

The following is the result: The peas came up, but owing to their having been sowed late and a spell of dry weather about that time, they failed; the tobacco sowed never came up; the Alverado and the Blue Stem Wheat, and the oats, all came up quickly and grew off finely, and for a time promised to do well; both kinds of Wheat were attacked with rust so severely, that I was enabled to save but a very small quantity of seed.

I succeeded much better with the oats; they came to maturity. I was enabled to save a sufficiency of seed to furnish each member of the Society with seed from the Potatoe Oats sowed, sufficient to secure seed. I consider the Potatoe Oat a valuable grain; they are said to weigh forty-five pounds to the bushel, and from the rapid growth and fine straw, I am of opinion they will do well in our climate and soil. The Oats and Wheat saved for the use of the Society I now present. ALEXANDER McDONALD.

The Report was on motion unanimously received and adopted.

On motion of Col. McDonald, the following resolution was unanimously adopted:

Resolved, That the thanks of the Barbour county Agricultural Society are due to the Hon. Dixon H. Lewis, for his kindness and attention to the Society in furnishing it with different kinds of rare and valuable seeds.

Col. McDonald then offered the following resolution, which was unanimously adopted:

Resolved, That the Barbour County Agricultural Society has sustained by the death of Maj. W. H. Snipes, 1st Vice President, the loss of one of its most active, useful and valuable members; and this community a citizen who enjoyed its confidence, and who was universally esteemed by all who enjoyed the pleasure of his acquaintance.

On motion of Col. Hunter, the resolution was directed to be communicated to the family of the deceased.

The President having resumed the chair, suggested to the Society the propriety of electing delegates to the State Agricultural Society at Tuscaloosa.

On motion of Col. Hunter, Gen. Shorter, Mr. W. B. Moore, and Dr. DuBose, were appointed a committee to nominate delegates.

The committee reported the names of Judge S. Williams, Col. A. McDonald, Col. John L. Hunter, Col. John Gill Shorter, and John A. Calhoun, Esq.

On motion of Dr. DuBose, a committee was appointed by the chair, to distribute the seeds alluded to in the report. The chair nominated Dr. DuBose, Gen. Shorter and Mr. Flournoy.

On motion of Dr. DuBose, it was voted that each member wishing seed leave his name with the Secretary.

On motion of Gen. Shorter, a committee of five be appointed by the chair to make arrangements for the celebration of the Anniversary of the Society on the 22d February next. The chair appointed Gen. Shorter, Messrs. Treadwell, W. Beauchamp, John M. Moore, and T. Flournoy.

The Society then adjourned to the next regular meeting. A. McDONALD, President.

E. C. BULLOCH, Sec'y. pro. tem.

At the Agricultural Fair held on the afternoon of 22d Nov., the following premiums and honors were awarded:

Best brood mare, Robert Ricks, $3.
Second best do., Mr. Posten, honors.
Best bull, Robert G. Ricks, $3.
Second do., Gen. Shorter, honors.
Best milch cow, Robert G. Ricks, $3.
Second do., Gen. Shorter, honors.
Best boar, Thomas Flournoy, $2.
Second do., Col. J. G. Shorter, honors.
Best Sow, Thomas Flournoy, $2.
Second do., Thomas Flournoy, honors.
Heaviest pig, six to twelve months old, W. Moore, $3.
Best counterpane, Mrs. W. Bates, $2.
Second best do., Mrs. W. Bates, honors.
Best article of negro clothing, Mrs. J. A. Calhoun, $4.
Best 3 year old colt, Robert G. Ricks, $2.
Best mule colt, John W. Johnson, $2.
One wolf-skin, Mr. Hendricks, $2.

RULES FOR WIVES.

1. Always receive your husband with smiles—leaving nothing undone to render home agreeable—and gratefully reciprocate his kindness and attention.

2. Study to gratify his inclinations in regard to his food and cookery; in the management of the family; in your dress, manners and deportment.

3. Never attempt to rule, or appear to rule, your husband. Such conduct degrades husbands—and wives always partake largely in the degradation of their husbands.

4. In every thing reasonable comply with his wishes with cheerfulness—and even as far as possible anticipate them.

5. Avoid all altercations or arguments leading to ill humors, and more especially before company. Few things are more disgusting than the altercations of the married when in the company of friends or strangers

6. Never attempt to interfere in his business unless he asks your advice or counsel; and never attempt to control him in the management of it.

7. Never confide to gossips any of the failings of your husband, nor any of those little differences that occasionally arise in the married state. If you do, you may rest assured that however strong the injunctions of secrecy on one hand, or the pledge on the other, they will in a day or two become the common talk of the neighborhood.

8. Try to cultivate your mind, so that, should your husband be intelligent and well informed, you may join in rational conversation with him and his friends.

9. Think nothing a trifle that may produce a momentary breach of harmony, or the slightest uneasy sensation.

"Think nought a trifle, thought it small appear;
Small sands the mountain, moments make the year,
And trifles, life. Your care to trifles give
Else you may die ere you have learned to live."

10. If your husband be in business, always in your expenditures bear in mind the trying vicissitudes to which trade and commerce are subject; and not expose yourself to the reproach, should he experience one of them, of having unnecessarily expended money of which you and your offspring may afterwards be in want.

11. While you carefully shun, in providing for your family, the Scylla of meanness and parsimony, avoid equally the Charybdis of extravagance—an error too common here, as remarked by most of the travellers who visit this country.

12. If you be disposed to economize, I beseech you not to extend your economy to the wages you pay to seamstresses or washerwomen who (particularly the latter) are too frequently ground to the earth, by the inadequacy of the wages they receive. Economize, if you will, in shawls, bonnets and handkerchiefs—but never by exacting labor from the poor without adequate compensation, incur the dire anathemas pronounced in the scriptures against the oppressors of the poor.—*Valley Farmer.*

INOCULATING CHEESE.—What will the ingenuity of man not contrive? A method has been discovered of inoculating cheese; or in other words, of transposing the character of an old cheese into a new one. This rather curious idea is brought forward in a communication to the Agricultural Journal, by John Robison, Esq., Secretary of the Royal Society of Edinburgh. "If it be required," says he, "to communicate to a cheese the flavor and appearance of an old one, it may be done by the insertion in the new cheese of proportions of the old one containing the blue mould. The little scoop which is used in samples of cheese, is a ready means of performing the operation by changing ten or a dozen rolls which it extracts, and placing them to disseminate the germ of the blue mould all over the cheese.

'A new Stilton cheese treated in this way and well covered up from the air a few weeks, becomes thoroughly impregnated with the mould, and generally with a flavor not to be distinguished from the old one. I have sometimes treated half a Lancaster cheese in this way, have left the other half in its natural state, and have been much amused with the remarks of our friends on the striking superiority of the English cheese over the Scotch one.'

If this ingenious plan be found really successful on repeated trials by others, Mr. Robison will deserve our thanks for bringing it forward. The next invention we shall hear of will probably be that of inoculating legs of mutton, and turning them into beef.—*Maine Farmer.*

SQUASHES.—It has been asserted, as the result of an accidental experiment, that squashes sown in the fall will survive the frosts of winter and spring, and will ripen much earlier than any which can be raised by sowing in the spring. Those sown in the spring and those sown in the fall, were, in the case alluded to, exposed to a severe frost; the former were killed, while the latter survived. It may be worth a more satisfactory experiment. The earliest sallads we know, are grown in this way. The same has been said of a species of beans, and even of potatoes.

To preserve good squashes in perfection, great care is necessary to keep them from the neighborhood of others of an inferior kind, and especially of pumpkins. If grown together, the good uniformly deteriorate, and the best squashes become bastard pumpkins. However mysterious this fact may appear, it is unquestionable; and it is probably to be explained on the same principles with a fact no less unquestionable, that the different species of corn and of grain always mix when they grow in the neighborhood of each other.—*Selected.*

An exchange paper states that the father of an interesting family, near Detroit, Mich., not long since stopped the only newspaper that he allowed himself or family, and solely on the ground that he could not afford the expense.—This man chews $14 60 worth of tobacco a year!

From the American Agriculturist.

TANNING ON THE PLANTATIONS.

INGLESIDE, Miss., Sept. 19th, 1843.

Tanning leather for the use of the plantation, is an item of good management that should not be overlooked by any planter. Nor would it be as much overlooked as it is, if the simplicity of the process was generally known—that process, I mean, that will suffice for making leather for home use. The *tanner* by profession, in order to prepare an article that will command a good price in market, and have a merchantable appearance, puts the hides and skins through a greater number of manipulations; and, that he may work to better advantage, has his arrangements on a more extensive scale.

The vats, tools, and implements, really needed, are few and simple. Four *va's* will generally be found all-sufficient; one for a *pool* of fresh water, and for *baiting;* one for *liming;* another for *coloring;* and a fourth for *tanning*. The best size, in the clear, is seven feet long, four and a half feet wide, and five feet deep. They should be placed so as to be easily and conveniently filled with water from a spring, running stream, or cistern. Dig the holes 9 feet, by 6½ and 6; if the foundation is clay, the depth need not be over 5 feet. Form a stiff bed of *clay mortar* in the bottom, on which to lay the floor, and on it erect the sides and ends of the vat, of plank of almost any kind, sufficiently thick to resist the pressure from without—two inches will be thick enough. When this is done, and the whole nailed fast, fill in the vacant space all round with *well-tempered* clay-mortar, ramming it effectually: it is on this, and not the planks, that dependence is placed for rendering the vat perfect. When well made, a vat will be good for a long lifetime—the *ooze* preventing the decay of any but the top round of plank. Such a vat will hold 15 large beef hides, (30 sides,) besides a number of small skins.

The material used for tanning, is the bark of the red or black oak, stripped when the sap flows in the spring, stacked and dried—of which about four pounds are supposed to be necessary to produce one pound of leather. There is an article occasionally used, called "catechu," which is an extract made from the wood of a mimosa tree, a native of India, half a pound of which answers the same purpose. Galls, willow bark, the bark of the Spanish chesnut, and common elm, as also sumach, are all used by the tanner. It has been recently found that the root of the palmetto answers an equally good purpose with the best oak bark.

Bark has to be ground as wanted; or if the quantity needed is small, and it is not thought advisable to incur the expense of a bark-mill (from $10 to $18,) it may be pounded in a large mortar, or beat up on a block. It will require one-third more of pounded than of ground bark, to afford equally strong ooze, which is the infusion of bark.

The principal tools requisite are a flushing-knife, currier's knife, a brush like a stiff horse-brush, and a fleshing-beam. The fleshing-beam is made by splitting in two a hard-wood stick of about a foot in diameter; inserting two stout legs, some thirty inches long, in one end on the split side, so that the other end rests on the ground, with the round side up; the elevated end being high enough to reach the workman's waist. A fleshing-knife may be made by bending an old draw-knife to suit the *round* of the fleshing-beam.

The skins of bulls, oxen, cows and horses are called *hides*; those of calves, deer, sheep, &c., are known as *skins*.

Fresh and dried hides receive the same treatment, except in the washing process. Those that are salted and dry, (and no hide should be dried with less than from two to four quarts of salt being rubbed on the flesh side—dried without salt, it is extremely difficult to soften them,) require to be steeped, beaten and rubbed several times alternately, to bring them to a condition sufficiently soft for tanning.

Green or fresh hides must be soaked in pure water from 12 to 24 hours, to extract all the blood, &c., and soften the extraneous fleshy matter, which must then be removed—throwing one hide at a time on the fleshing-beam, grain or hair-side down, and scraping or shaving it off with the fleshing-knife, which must be somewhat dull or the skin is apt to be cut. They are then put in the liming vat, which is supplied with strong lime-water, by filling the vat a little over half full of water, and adding thereto four bushels of unslacked (or of air slacked) lime, or at the rate of two-thirds of a bushel of lime to the barrel of water. This will suffice for fifteen hides; each time that they are removed and a fresh lot of hides put in, add another bushel of lime, which will keep up the strength for a twelve-month. Before using, stir the lime well up, and while it is thus mixed with the water, put in the hides evenly, so that the lime will settle on every part of them. They are to remain here from ten to fifteen days, or for three or four days after the hair will rub off with the finger completely and with ease. While in the liming-vat, they must be moved up and down every other morning, to expose them to the air, and to the equal action of the lime. Being now ready for unhairing, cut each hide in two, by slitting them along the centre of the back with a knife, forming them into *sides*. Throw ten or twelve of these sides on the fleshing-beam, and strip the hair off with the knife; and as they are unhaired, throw each one into the vat of fresh water to bait or soak. When the lot of sides and skins in hand have been all unhaired and thoroughly washed, throw them again, and at once, on the fleshing-beam, with the grain or hair side up, and work them over (rub and press them) with the knife until all the gummy or mucilaginous matter is worked out. This should be repeated two or three times during ten or twelve days, being each time baited anew in fresh water. And this working over must only be done when the sides feel soft and smooth to the touch; as they will at times, from some unexplained cause, feel rough, at which time they must not be worked over. While they are thus baiting, they must not be neglected, or they will soon spoil. Tanners are in the practice of adding 1000th part of sulphuric acid (oil of vitriol) to the last bait, which has the effect of swelling the pores and distending the fibres, and thus rendering the skins more susceptible to the action of the ooze: forty-eight hours generally suffice for this last baiting.

In the meantime, some good strong ooze should be prepared for the first tanning process, called *coloring*. Fill a vat a little more than half full of water, and add bark, in the proportion of 1½ bushels of ground, or 2 bushels of pounded bark, to the barrel of water, which will bring the vat up to about two-thirds full. When the bark has soaked from four to five days, the sides are put in, and allowed to remain 15 days; during which they must be *once* well and carefully fleshed and worked over, and must be drawn up and down every morning, for the first week at least, and the bark well plunged or stirred up, to have them color evenly.

After this, the vat being now two-thirds full of this same ooze, after drawing out the hides, lay a good coating of fresh bark, of say an inch thick, on top of the water, on which it will float, lay on this a side, spread out evenly; and if it has to be lapped over in any part, lay on more bark until it is all well coated, taking care to place those hides at the bottom of the vat now, that were at the top last time. On this side lay an inch-coating of bark, and on that another side, and so on, with alternate layer of bark, until the vat is full, or the sides all laid away.

In this, which is call the first bark, the sides must lie four weeks. They are then drawn out, and the spent bark taken out with a skimmer or drainer. The sides are then replaced as before, with alternate layers of fresh bark, in the same ooze, which has acquired some additional strength, notwithstanding the amount of tannin and extractive matter, contained in the bark, that has become intimately combined with the animal fibre of the hide. In this second bark they remain six weeks undisturbed, when they receive a third bark, in the same way, in which they are left another six or eight weeks. Three barks will suffice to tan deer, hog, calf, and other small skins; four barks will make good sole leather, but five are preferable.

The tanning process being completed, sole leather is taken out of the vat, rinsed effectually, and dried in the shade, hanging the sides up by two of their corners to joists, where they may remain until wanted. Those sides intended for upper and harness leather, (which are those of cows, &c.—the largest and thickest bullock hides being used for sole leather,) as also deer, hog, and other small skins, being thoroughly rinsed, are spread out on a strong table, with the grain or hair side up, and scoured with a stiff brush, like a very stiff horse-brush, occasionally throwing on pure water, until all the ooze is scoured out. Tanners use the edge of a stone, made smooth, to assist in rubbing out the ooze, and all the water that can possibly be rubbed out. They also use what they call *a slicker*, being a dull edge of copper of about six or seven inches long, set in a piece of wood, to serve as a handle.

After they are all served thus, and rubbed as dry as possible, the table is cleaned off, and the skins thrown back upon it, grain side up, and are rubbed with tanner's oil (cod-fish oil) as long as the leather will receive it. Harness leather must be completely saturated. As they are oiled, fold them up and lay them aside.—When they are all gone over, lay one on the table at a time, flesh side up, and with a rag rub on all the dubbing that the leather will absorb. Thin hides require but a small quantity; harness leather must have a heavy coating.

Dubbing, which consists of equal parts of tar and tallow, melted together, and well mixed, must be made the day previous to being used. Lard may be used in place of tallow, but will require a lesser proportion of it. Each side of leather is then hung up by two corners to joists, there to remain until perfectly dry, or until wanted.

If iron or steel touches a hide during the process of tanning, when in the least wet, or even moist, it will discolor it, forming an indelible black mark.

To blacken harness or other leather, take the skin when completely dried, and if any greasy spots appear, showing that more oil or dubbing has been applied than the leather could absorb, wet the spots with a little strong ooze, and scrub them out with the brush. Then apply a good coat of copperas (sulphate of iron) dissolved in ooze, until the leather has a good color all over. After this, when dry, put on another good coat of oil. The leather may then be smoothed off with a rounding edge of polished steel, or glass, or stone.

T. AFFLECK.

From the Southern Planter.

HORSES,

Mr. Editor—The ordinary means of purging a sick horse are so slow in operating, that, in many cases, they do no good. I send you a very simple *recipe* with which some of your readers may not be acquainted, which I have never known to fail, and regard as the best and simplest. I saw it many years ago in the American Farmer, and have tested it.

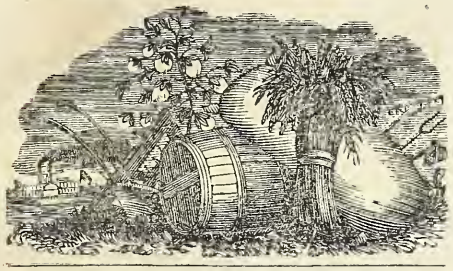
"Take a piece of chalk about the size of a walnut, pound it in a mortar, or wrap a rag around it and reduce it to powder with a hammer or any thing else—put the powder into a quart bottle—pour common vinegar into the bottle until the effervessence prevents your pouring more, and (having the horse ready) drench him with it. But little vinegar can be gotten into the bottle the first time, so that you will have to pour more into it, and drench a second time. Ordinarily a pint will do. In cases where it does not operate in *five* or *ten* minutes, persevere in the dose, and in a very short time the suffering animal will be well again."

I concur in the opinion that every farmer who

wishes to benefit others should not be ashamed to back his recommendation by his *name*. If *he* be ashamed of it, who ought to confide in it?

Very respectfully yours,
C. W. Gooch.

Airfield, June 20, 1843.



WEDNESDAY, DECEMBER 6, 1843.

Back Numbers.—All new subscribers to the "Southern Cultivator" can be supplied with the back numbers.

TO OUR FRIENDS.

In the appeal which we made to you in our last, for the extension of the circulation of the "*Southern Cultivator*," we omitted to state the necessity of having the result of your labors by the first of January, in order to afford us some idea of the number of papers necessary to be issued. As this is very important, we hope you will bear it in mind and send us your lists of subscribers by that time. We hope that every friend of the work will unite in a zealous effort to extend our circulation.

AGRICULTURAL FAIR.

We are indebted to some friend, who will please accept our thanks, for a copy of the "*Southern Shield*," containing a report of the Fair of the Agricultural Society of Barbour county, Ala., which will be found in another part of this number.

The existence of an Agricultural Society in the newly settled county of Barbour, and the deep interest manifested in the cause of agriculture by the members, afford food for reflection, while they serve as an example worthy of imitation for our planters in the older settled States of South Carolina and Georgia. We therefore commend the subject to the calm and dispassionate reflection of our readers. Certainly if the wise forecast of the planters of Barbour should suggest the necessity of forming an Agricultural Society for the preservation and improvement of their rich, fresh lands, and the introduction of the most approved and enlightened system of culture, how much more imperious the necessity for the organization of such Societies throughout every old settled county in Georgia, where a system of culture, the most ruinous to the soil ever practised by any people, has exhausted her lands, and driven many of her most valuable citizens to seek a home in the Southwest? We have so often alluded to this subject, and so frequently urged upon our readers the necessity, the great importance, and the lasting benefits of Agricultural Societies, that we feel that we almost subject ourself to the suspicion of being a monomaniac upon this question; for we have not only urged it again and again in our editorial remarks, but we have availed ourself of the lights afforded by the experience of others, and have given our readers their views also. It has often occurred to us as strange, passing strange, that intelligent men, and even planters themselves, in the prosecution of every other branch of business, unite their councils to direct their energies the more wisely; and for the attainment of their objects with the greatest possible certainty and precision, they avail themselves of all the lights which the experience, investigation and practical operations of others can afford; yet in Georgia, save in a few, very few, counties, men will not, or have not, associated themselves together for the purpose of imparting information in that important branch of business upon which is based the prosperity of a nation of people in every department of science or mechanics. Can any of our readers account for this extraordinary state of things—this paradox in our characters—this evident disregard of our immediate private interests, and this virtual declaration to the world, that we are either already sufficiently learned in the science of agriculture, or too indifferent and indolent to make an effort for the improvement of our own, or the system of others? Can it be that we are like the boy, who persisted in carrying a stone in one end of his bag and a pumpkin in the other, simply because it was the established custom of his father?—Certainly every intelligent planter must have long since perceived, if he ever for one moment attempted to unveil the future, that the system of our fathers would assuredly, at no very distant day, result in the total destruction of our soil, and the consequent depopulation of our State. Can we not then persuade or invoke them to stay their march, to turn aside from a course which will entail poverty and distress upon themselves and their posterity, and adopt a more wise policy, a more enlightened system, which will secure peace and plenty, and contribute, in an eminent degree, to the cultivation of the intellect, the refinement of our feelings, and the promotion of domestic happiness? With these remarks, (already extended much beyond what we had designed,) we for the present leave the subject to the consideration and reflection of those for whose immediate benefit we have urged its importance.

BOMMER'S MANURE.

Desirous to afford our readers every facility for obtaining information in relation to this important subject, which is daily attracting more and more attention throughout the Union, we have transferred to our columns, in this number, the Card of Mr. Bommer, to which the attention of the reader is invited. The agent of Mr. Bommer is now engaged on the plantation of one of our planters, near the city, in making a heap of manure on the Bommer system, and we hope to be able, in a short time, to favor our readers with the result of his labors, together with such other information as we may deem of value for the consideration of planters.

Large Cotton Stalk.—R. P. Miller, Esq., of the parish of Concordia, has sent the editors of the Intelligencer a cotton stalk thirteen feet long, which they say has the appearance of a vigorous young sapling.

SWINE MANAGEMENT.

In managing hogs, it is important that pigs should be farrowed at seasons of the year neither exceedingly hot or cold. April and September are the best months for the sows to pig. For this purpose they should go to the males the last of May or first of June, and in December. It is a good rule never to let breeding sows get very poor or very fat. From the time they go to the boars till within a month of pigging they should be fed regularly, but only in sufficient quantities to improve them slowly. As the time of pigging approaches they should be fed more bountifully. But if they become too fat, they often overlay their pigs, and are not usually careful with them. Many rules have been given for the management of sows at farrowing, but only a few plain directions will be of service:—1st. Let no other hogs interfere with the sow; and 2d. Be certain she has water and a pleasant shelter in the lot. If she should happen to make choice of an unsheltered spot for her bed, a few planks, or a board shelter will protect her from the sun and rain.

Young pigs should become fat as soon as possible, and be kept so till they are ready to butcher. To effect this matter, the dams should have an abundance of rich food, such as kitchen slops, roots, boiled corn, &c.

It is a good practice to have a small pen with a hole, to admit the pigs, and a low trough for them to be fed in from the time they are two weeks old.

When the pigs are from six to eight weeks old, if they have learned to eat well, they should be weaned. At this season there is greater difficulty than any other. Unless they have close attention they will become poor, sink behind the shoulders, and scarcely ever recover from it.—Let them have food regularly five times per day, and it should be such as will suit the stomach, and be most nutritious. Slops will answer a good purpose for part of the time, but the food should vary every day. Milk, boiled meal, slops, roots, and dry food, as corn, should be given daily. Hogs should have water at all times, and if salted every day, they will do the better for it. Grass and clover are always acceptable to swine, and cymlings, pumpkins, and peas are very good, and artichokes, in winter, (except when the ground is frozen) are unequalled, particularly if the hogs have salt and a little dry food daily.

Care must be taken that hogs do not occupy the same bed too long, and by all means they should be kept from sleeping in stables, about manure heaps, in shucks, or wet or old straw.

The cheapest pork is that which is made of pigs dropped in the spring and slaughtered the December following. By this process a winter's feed is saved, and by "pashing" the pigs will weigh from one to two hundred pounds at eight or nine months old. For large pork, the year olds will do tolerably well, but we think it bad economy to have killing hogs more than twenty months old.—*Tenn. Agriculturist.*

A Curious Agricultural Experiment.—The following novel and interesting experiment has lately been made by Mr. A. Palmer, of Cheam, Surrey: In July, 1842, he put one grain of wheat into a common garden pot. In August the same was divided into 4 plants, which in three weeks were again divided into 12 plants. In September these 12 plants were divided into 32, which in November were divided into 50, and then placed in open ground. In July, 1843, 13 of the plants failed, but the remaining 38 were healthy. On the 19th August they were cut down, and 1,972 stems, with an average of 50 grains to a stem, giving an increase of 98,600.

One of the stems has been sent to us as a sample, which is rather more than six feet long, and stout in proportion.—*London paper.*

To Cure a Scald or Burn.—Dissolve a piece of alum, about the size of a walnut, in a half pint of warm water, in which immerse a linen cloth. Apply the wet cloth on the part affected, and let it lie until relief is obtained.

SELECTING SEEDS.

Great improvement may be made by a judicious selection of seeds. In most all crops, some plants will be found more early, or in some respects superior to others. From such seeds should be carefully selected.

If a cultivator desires to have any production earlier than usual, after procuring an early kind, let the first seeds that ripen, on a well grown and productive plant, be secured, and so proceed year after year, and in this way a variety will be obtained that will excel in earliness.

Every variety of vegetable may be rendered more productive, by selecting every year the seeds of the most productive and well formed plants. And this method of improvement will be found the cheapest that can be pursued, as the difference in the cost of good and poor seed is a mere trifle.

Select peas for seed that grow in long, full pods, on vines that bear abundantly, and if you would have them earlier, take those which ripen first. Choose beans in the same way. Select seed corn from stalks that bear two or more good ears, and take the largest and best formed ears. Choose from stalks that are large at the bottom, and run off to a small top, not very high.

If you would have early onions and few scullions, select for seed a few that ripen first, and have a good form. Select the handsomest turneps for seed, having just the form you would choose, if you would have fine crops for the market; and by this selection for years, you will get a variety that may be relied on.

Follow the same rule in every thing. Like produces like, is a general law of nature; the same in the vegetable and animal kingdom: there are some exceptions, but not enough to affect materially the general crop of production, and by these exceptions we may profit; for when the exceptions are an improvement, we may follow them out, and in a short time establish a new race or variety; but when the exceptions are inferior, we can reject them.

These exceptions to general rules offer great advantages, and a wide field for improvement, while the disadvantage is a mere trifle. As a spark will kindle a great fire, so from a single seed of superior excellence, large crops of this superior production may be raised, and widely disseminated for the benefit of thousands.

There is no subject of improvement so much neglected as this; it is within the means of all, and yet few give attention to it. Too many are content to plod on in the old way, and while they spend much in manure and cultivation, they neglect a much cheaper way of improvement, or to avail themselves of those made by others in this way, when at less expense they could accomplish it, and perhaps more effectually.

We selected seed from the first pumpkin that ripened, in a variety which we cultivated for several years, and last year some were ripe in two months and five days from the time of planting. Numerous instances could be cited of the above remarks, but it is so clear to every common observer, that no evidence is necessary; but it is important that they be reminded of a subject so much neglected, and with so much loss.—*Selected.*

PERIOD OF GESTATION OF DOMESTIC ANIMALS.

—It is very important to farmers to know the length of time that different animals go with young. We accordingly give the period of those which most concern him as near as we can ascertain it.—*American Agriculturist.*

SUPERIOR BREAD.—Melt 2 oz. of butter in a pint of warm water, then add a small tea-spoonful of salt, 1½ lbs of flour, and two table-spoonfuls of yeast. Now beat well the yolks of 3 eggs and stir them in, then beat the whites to a stiff froth and stir them in also. They must be the last thing put in. Beat the whole well together from 8 to 10 minutes, or until the mixture will not adhere to the spoon. Fill the pans about three quarters full and set it to rise, which will take from 3 to 4 hours. It must be baked in the pans in which it is set to rise, and is to be eaten moderately warm.

A DUTCHESS COUNTY LADY.

AUGUSTA MARKET.

TUESDAY, December 5—P. M.

Cotton.—The market today has been rather active, and operations have been fair, with a slight advance in rates; and the firmness which characterised the market throughout last week has been fully maintained.—We quote 6½ to 8c as extremes—principal sales 7⅜ @ 7⅝ cents.

Exchange.—Checks on New York, Charleston and Savannah, are abundant at par. Central Bank 4 to 5 ℔ cent dis. Sales of State 6 ℔ cent Bonds have been made at 80, at which rate they are very firm and tending upward.

GARDEN AND FIELD SEED.

A GENERAL assortment of fresh and genuine GARDEN and FIELD SEED, among which are the following:

Red and White Clover,
Blue and Green Grass,
Rye and Orchard do.,
Timothy and Herds do.,
Millet and Lucerne do.,
Seed Corn of every valuable variety,
Seed Wheat,
Buckwheat and Potato Oats,

Kept constantly on hand by the subscriber, all of which are offered for sale at very moderate prices. All orders, by mail or otherwise, executed with neatness and despatch.

VOL. I. AUGUSTA, GA., DECEMBER 20, 1843. No. 26.

ORGANIC CONSTITUENTS OF SOIL.

Dana's Muck Manual is one of the most useful works for the farmer ever published.—The reader who will peruse diligently the extract below will be amply rewarded for his labor.—*American Farmer.*

ON THE ORGANIC CONSTITUENTS OF SOIL.

The mineral elements of soil, become part of plants. Under the influenee of the mysterious principle of life, they no longer obey the chemical laws. It organizes inorganic matter. To what laws obedient, to what purposes subservient, are the elements of soil during the brief moment in which they are endowed with life, it is not intended to inquire. Plants by their living power select from the 55 elementary substances fifteen only; of these, three are gaseous, oxygen, hydrogen, nitrogen; one, chlorine, exists only as a component of a salt, as in common salt; seven belong to the class silicates, second division, and four to the class urets.

Every plant does not, nor does every part of the same plant contain the same elements; but every part of the same plant at the same age, probably contains the same elements, united in definite proportions. Whenever plants die, their elements are again subject to the laws of affinity, and during the decay of vegetables, they return to the earth, not only those substances which the plants had taken from the soil, but also those which have been elaborated by their living structure. The former are silicates and salts, or the inorganic elements, the latter are the organic parts of soil.

In the first edition of this work, chlorine was not enumerated as an element of plants. Its presence in them was considered accidental, because its source was not detected in the rocks, from whose ruins soil has been formed. Plants are good analysts, and may detect elements where chemistry cannot; yet it is difficult to believe that chloride can exist as abundantly in soil, originally, as their presence in plants indicates, and yet elude our process. The possible existence of chloride of silican has been noticed. If this is not the source of the chlorine of plants, it must be supposed to be evaporated as a chloride from the ocean, and consequently to exist in that state, dissolved in air. If derived from this salt in soil, then that is extraneous.—Its origin was suggested to be oceanic. An examination of the rain-water of each fall, since March last, has shown that this suggestion is correct. Probably muriates are universally contained in rain-water. As, therefore, common salt, the chlorine, and soda of plants, is derived by evaporation from sea water, then as sulphate of lime has been detected in snow and hail, it becomes a question, whether other inorganic salts of plants may not have a similar origin, and exist dissolved in air.

It is thus seen that soil presents itself in a new view. Soil consists of two grand divisions of elements. Inorganic and organic. The inorganic are wholly mineral, they are the products of the chemical action of the metalic, or unmetalic elements of rocks. They existed before plants or animals. Life has not called them into existence, nor created them out of simple elements. Organic elements are the product of substances once endowed with life. This power influences the elements, recombines them in forms, so essentially connected with life, that they are, with few exceptions, produced by a living process. They are produced of living organs, hence termed organic: and when formed are subject to chemical laws. The number of elements in the inorganic parts of soil, is twelve. Oxygen, sulphur, phosphorus, carbon, silicon, and the metals, potassium, sodium, alumnium, magnisium, iron, and magnese. The number of elements in organic parts of soil, does not exceed four, oxygen, hydrogen, carbon, and nitrogen.

The great difference between these two divisions is this, that while the inorganic are simple combinations of two elementary substances, the organic are combinations of three or four elements, but never less than three. These are variously combined. They have formed the great body of vegetable products; continually changing, the mere abstraction of a part of one of their elements forms a new product. The three elements exist generally in such proportion, that the oxygen and hydrogen would, by their union, produce water without excess of either element, while the carbon would thus be liberated. It would be found free were it not also acted upon by air and moisture, and changed to carbonic acid. There is not oxygen enough in the organic part to convert the carbon into carbonic acid, and the hydrogen into water.—They are constantly changing, assuming new forms. This susceptibility of change is the foundation of tillage.

The relation of agriculture to silicates and salts, and to the composition of plants alluded to, (89.) is of the highest interest. As silicates and salts compose all the earthy ingredients of soil, so are they equally constant in plants. The deduction to be drawn from this, is the sixth principle of agricultural chemistry, *soil, consisting chiefly of one silica, or salt, is always barren.*

It is not probable that soil, thus chemically constituted, exists. Admitting such to occur, even then, when dressed with food of plants, it would not be fertile. The want of a mixture of earthy ingredients, which are as essential to the growth of plants as are air and moisture, would effectually prevent the growth of crops. Only a portion of the elements, thus essential to plants, exists in them in that state in which they exist in soil. The silica, and potash and lime, exists in plants as in soil, as silicate of potash, and sulphates and phosphates of lime and potash. When the ashes of plants are examined, we find carbonate of bases, which did not exist as such in the soil. A large portion of carbonates of lime and potash is found in ashes.

The origin of these is to be sought in acids, which, by heat, produce carbonic acid. This is the effect of heat upon all salts formed of vegetable acids. Such as tartaric, malic, citric, oxalic and acetic acids. The inorganic elements of plants exist in combination chiefly with organic or vegetable acids. Each plant forms acids, in definite quantity, proportionate to the size, age and part of the plants; the acid being constant, the bases to saturate them will be equally constant.

A curious and beautiful chemical law governs this satuaration of the vegetable acids. It is the law of isomorphism, or the law of similar forms. In minerals which are crystalized, it was formerly thought that similarity of eternal form, indicated identity of chemical composition. Later observation has established the fact that minerals and salts exist, with perfect similarity of external form, yet of totally different chemical constitution. For example, the alumina in alum, may be replaced by oxide of iron. The form will not be changed; but all its chemical properties and relations are destroyed. This is called an isomorphous substitution, of one element for another, which produces a like form. The law of this substitution is, that the body replacing another must be, not an equal, but an equivalent proportion (56;) that is, replaced by a proportion containing the same quantity of oxygen.

The relation between agriculture and this law is so wisely and beneficially ordained, that it might well be called a law of compensation, by the Natural Theologian. It is a well established fact, that plants, growing on soil containing a due mixture of earthy ingredients, always select a due proportion of each, according to their functions, yet, if to such soil an excess of either of the alkalies, or of the alkaline earths is given, an excess of potash, soda, lime, magnesia, may be taken up by the plants, to the exclusion of the usual proportion of another; hence it may be established as the seventh principle in Agricultural Chemistry, one base may be substituted for another, in an isomorphous proportion.

This is a very important law in the agricultural relations of the inorganic parts of soil.—Whatever may be the office performed by these, in the living structure, none is of higher value than this, that they may be thus substituted, the one for the other. It is a fact of the highest practical value. Its value will be perceived, when it is considered, that if soil, containg originally all the elements essential to a crop, becomes exhausted of one, yet another may be substituted, which combining with the organic acid of the plant, enables this to perform and perfect all its functions. If a crop fails, this is often charged upon the deficiency of lime in the soil. It has been already shown that this is quite impossible, yet granting it true, so long as the law of isomorphism exists, so long may potash, soda, magnesia, that is, ashes, supply the place of lime.

Isomorphous substitutions in plants, relate only to the bases combined with the vegetable or organic acids. The mineral or inorganic acids exist already saturated in the soil, as sulphates, phosphates, or muriates.

In consequence of the law of isomorphism, the oxygen is the bases of organic acid salts is a constant quantity, although ashes of the same plant may, by analysis, show a great diversity of composition; this can arise only from the fact that the organic acids exist, probably in a definite proportion in each family of plants.—The acids are formed by the essential vital functions of the plant. To the perfection of this process, the silicates and salts of the soil are not less necessary than is life to the vegetable; but though one element may be substituted for another, yet no one element may supply the place of all others. This is a problem yet to be solved. Nor may any possible mixture of mere silicates and salts give fertility to a barren soil. Fertility depends on the presence in soil of matter which has already formed a part of a living structure, or the organic elements of soil.

The inorganic are simple combinations; the organic simple in number, but wonderful complex in their combinations. It is an establish-

ed fact, that all complex compounds are unstable. They are prone to form new combinations. The more complex, the easier decomposed is any compound. The more complex the more liable to decomposition. Hence, the moment life departs, the plant or animal speedily undergoes new changes; its elements, which life had organized, obey now, not the law of life, but the laws of chemistry. The solids and fluids of a living body, when life ceases, escaping in part as air or gas, leave in a solid form, a substance differing equally from any living organic product, and from inorganic elements.—The product of the spontaneous decomposition of organic substances, still may exhibit the character which distinguishes this division, viz: complexity, great susceptibility and ease of decomposition.

Hence, in the products of the decomposition of organic bodies, a variety is formed, differing according to the circumstances, and the time, and progress of decay. However varied, there is one constant product of organic decomposition in soil, which is ever the result of that process, in or upon the earth. The product is termed GEINE. *Ge* is the Greek for earth, and the suffix *ine*, is in conformity to chemical names, given to those vegetable or other organic products, whose independent existence has been determined; for example, quinine, morphine, &c.

While the great mass of organic matter of soil, is a well defined chemical compound, termed geine, consisting of carbon, hydrogen and oxygen, there are traces of other general products of decay, which, in addition to the elements above, contain nitrogen. There is thus naturally pointed out a division of the organic matter of soil, in two classes; that which does not, and that which does, contain nitrogen.

The first class, or non-nitrogenous, comprises three substances, which have been termed, 1st, extract of soil, or of humus; 2d, geine, or humic acid; and 3d, carbonaceous soil, or humin. These are chemically the same, passing from one state to the other, without changing the relative proportions in which they were combined.

From the Southern Planter.

BOMMER'S MANURE METHOD PUT IN PRACTICE

We extract the following certificate of the value of the manure made by Bommer's process from the last number of the Cultivator.—We have in our own possession the most satisfactory testimonials of its efficiency in producing speedy decomposition, and of the *apparent* value of the manure. But nobody hereabouts has yet had an opportunity of testing its effects upon a crop; although no one who has seen the manure after it is made, seems to have any doubts upon this point. As far as our information and experience go, the time required to produce perfect decomposition is rather underated. Of course different materials will be longer or shorter in rotting, but we rather think that the average will require from four to six weeks.—But our information is drawn from experiments made during the last summer, when the process was undoubtedly much retarded by the excessive rains for which the season was so remarkable.

"*Messrs. Gaylord & Tucker.*—Being a subscriber and constant reader of your valuable agricultural publication, I frequently find there, articles on 'Bommer's Method of Making Manure.' As these articles are chiefly from the pens of agriculturists who have followed this method with entire success, it affords me unfeigned pleasure to be able, on my own behalf, also to bear testimony to the value of this method, and through the medium of your paper, to make the results of my experiments and operations known to my fellow-citizens. This I do, both for the sake of bringing before the public the great advantages derived from using the method spoken of, and the benefits insured me by its application, and at the same time in order to render a deserted tribute to the truth.

"On purchasing Bommer's method last spring, I immediately prepared a heap in the presence of a few neighbors. I followed strictly the directions laid down in Bommer's book. After the lapse of a fortnight, the heap was opened in the presence of a number of farmers, and our astonishment cannot be conceived on seeing the metamorphosis which had taken place, as we found all those weedy and stramineous materials of which the heap had been constructed, reduced to rich black manure, having an ammoniac smell, much more pungent than the best stable manure. Beholding so surprising a result, the farmers present formed themselves into a public meeting, and in that capacity nominated a committee from their midst, who were charged with the preparation of a report of what we had seen, to be sent to the agricultural press.

"I ploughed in this manure into one-half of a field intended for potatoes, and in order to institute a comparison of effects, I put the same quantity of my best stable manure into the other half of the field. The effect on the soil was nearly the same with both these kinds of manure; but the vegetation on that part of the field which had been furnished with Bommer's manure, was more luxurious and the foliage of a deeper verdure, which I attribute to the richness of the saline matter which it contains, and which alone preserved the humidity of the soil during the severe drought of this last season.—It is proper to remark also, that in the composition of the Bommer manure, I employed simply such doses of the ingredients as were absolutely necessary to insure success in the operation of making it, and if I had increased these quantities, there is not the least doubt that the result of the Bommer manure would have been very far superior to that of any horse manure.

"Perfectly satisfied with my experiment and its results, I have put up fixtures near my barn-yard for the purpose of preparing large quantities of this manure; and within the last two months I have made three heaps, which have yielded me between 200 and 300 loads of excellent manure. The last heap was composed entirely of 100 loads of sedge grass, nearly dry, with which I intermixed 40 loads of swampy matter, such as exists on my farm. All my outlay in purchasing ingredients to form the lye for this last heap, amounted to between $20 and $30, and in disbursing this trifling sum, I have made a heap of manure, which I would not dispose of for $250.

"I shall prepare other heaps of manure before the winter sets in, and those who may be desirous to see me at work and to assure themselve of the truth of what I have said, need only call at my farm, and judge for themselves. The benefits which I derive from using this method are not inconsiderable. Before becoming acquainted with it, I purchased every year from three to five hundred dollars worth of manure, which I needed over and above that of my own farm-yard, for the two hundred acres which I have. Now I do not purchase one penny's worth, and I can make double the quantity if I choose. I have the advantage of producing my manure in the sowing and planting season. I can make it more or less strong, more or less fermented, so as to suit the soil and kind of crop for which I want it; I spread and plough it while it is perfectly fresh, and consequently in all its strength. These are some of the results experienced by me in using Bommer's method of manuring land.

JERRIT KOUWENHOVEN.

Flatlands, L. I., Sept. 15, 1843."

In seasons of distress, the mind recovers itself by taking hold first of one hope and then of another, until all its functions are restored; and it feels once more, that there is pleasure in looking forward and anticipating the light and warmth of to-morrow's sun.

The range of earthly good is narrow and soon trodden; after a short time there is no variety, and the enjoyment is without hope.

CORN.

We take the following extract from "a letter from N. Goldsborough, of Talbot county, Md., to J. S. Skinner, as published page 165, in American Farmer," for the purpose of calling the attention of our readers in the South to the mode of planting corn where large yields are made—of "cyphering" a little—and that we may ask it of some friend to try the experiment of planting more corn to the acre. To the extract:

"I had grown as large corn as I had ever seen in field culture, at 4 to 4½ apart from hill to hill, and I was satisfied that the only mode of making a number of bushels per acre was, to increase the number of stalks. Accordingly, an acre was in drill 4 ft. 6 in. apart from row to row, and 18 inches distant in the row—two plants in a place—the product 123 bushels and a peck. The other acre was crossed at 3 feet each way, and two stalks to the hill—93 bushels and a peck the product. The first acre, however, was the best land."

Our readers will now please to note that at 4 to 4½ from hill to hill there are 2722 to 2151 hills, say 2722, and 5444 stalks; 4 ft. 6 in. by 18 in., 6453 hills, and 12,906 stalks; 3 ft. by 3 ft. 4840 hills, and 9680 stalks.

By the single rule of three, if 9680 stalks produce 93 bushels, 12,906 stalks will produce 123 bushels, and nearly another, wanting some 70 stalks—which was verified by the turn out very nearly. Again, we find by dividing each number of stalks by the product made from them, that it required 104 stalks and a fraction to make a bushel; and if we divide the smaller number of stalks, as we usually plant in this country, by the 104, we find the product would be 42 bushels and a fraction, which is about as good a return as we have of our choice lands.

Our notion is, if a larger product be wanted, we must resort to the same reasoning that Mr. Goldsborough adopted. We are aware that we are met at the very threshold, by the every-day expression, that "corn will not bear close planting in the South;" but this objection has become stale. Were we to listen to this kind of argument, we might despair of ever seeing any improvement effected.

We think pretty much of corn as we do of grain: if there be sun, air and strength of land sufficient to grow a crop of corn and such crops of weeds and grass as do grow, we might, with perfect safety, grow more corn. Would any one suppose that the land, having ability from named causes to grow such grass as it does, would not grow peas, or pumpkins or beans? Then why not some more corn? Admit that our summers are hot and dry; yet, if the land were shaded by early pea and potato vines, the crop would not suffer so much. And a matter of vast import—if we can, by any mode of *culture*, make double our present yield, we could take more time in the spring to plow deeper, plant better and cultivate earlier, so as to stimulate the corn to a more rapid growth and earlier fructification, therefore earlier out of the way—and if thicker on the ground, would shade the land earlier, and create less necessity for the heavy plowing in of grass, &c. We would require less land to make a larger crop, thereby giving us some time to manure, and thus add to the great ultimate desideratum of all good farmers—the permanent improvement of the soil.

We have had some little experience in these matters, if being told we would make no corn for the last three years should make it more impressive. Our crop of '40 was left thicker than we had before grown, because we could not avoid it; several who saw it said "it was a pity it could not be thinned out, it was so promising;" in '41, we left it thicker, being pleased with the yield of '40; we were told, "it is too thick," "it will not make a crop," &c.—but it did, and better than '40, because not plowed so late nor so deep when it was cultivated; again, in '43 we were told we had "left doubly as much corn on the ground as should be," that we "would not make half a crop"—and so we feared at one time ourself. That field with which our N. G.

N. was so pleased, though thin land, has been gathered, and has yielded an average of 30 bushels; and having been with the wagon, knowing how many rows it required to fill the wagon, through nearly the whole field, we verily believe much of it yielded over 40 bushels.

We have frequently, in private conversations with friends, urged the advantage of closer planting; and in each of these three crops, there were times that we feared we had "paid too dear for our whistle," not only from the general expression of opinion adverse to our plan, but from appearances. Those who plant cotton cannot give corn the early pushing that it should have, and it is made to suffer from not being plowed early enough, and afterwards also, from the necessity of plowing too deep, to enable us to cover grass. This is one reason why, at a certain period of its growth, it has an unfavorable appearance. We intend to devote a portion of our time hereafter, as well as a portion of labor and land, towards testing close planting of corn, as well as large yields of cotton, and have marked off some few acres on a piece of level land, where the pea-vine has reigned lord and master for two years, intending to try for 100 bushels of corn per acre—the land cleared in '33, in cotton some 7 years, corn 2 years, and peas 2 years—not certain but that it was in cotton 8 years and corn only one—not over ordinary land for these parts when cleared.

We are anxious to fasten it on our readers, that we can do any thing that any other people can; and then we will see attempts made at it; but so long as "we can't do this or that," is at our tongue's end we never will. Let us all try to do more towards making *our Mississippi* independent, and each other happy—and it will be done.—*South-Western Farmer.*

From the American Farmer.

THE MEDITERRANEAN OR GERMAN WHEAT.

The following communication upon the origin and quality of this wheat will be read with interest, and we sincerely thank our esteemed friend Dr. Horton for the pains he has taken to make its merits known. We agree with him that every *Country* should have its Agricultural Society—nay we will go further and say, that every *election* district should have its Agricultural Club.

Mr. Editor,—Feeling a lively interest in every thing that relates to the prosperity of the agricultural community, and having, as you know, taken much pains to find a preventive to that scourge of our staple crop, the Hessian fly I a short time since addressed a letter to James Pannell, Esq., an intelligent farmer of this county, for all the information in his possession concerning the "Mediterranean wheat." I also requested him to obtain the like information from Mr. Thomas Hope, who, I was informed, was the first to introduce this wheat to our country.

Herewith you have Mr. Pannell's reply to my letter, which, for the information of our agricultural friends you will please to publish. It will doubtless be a matter of surprise to you, as it was to me, that this wheat has been cultivated in Hartford county thirteen years! It must place some of our friends, who claim the credit of having introduced it, quite in the back ground.

NEAR CHURCHVILLE, }
21st Nov., 1843. }

Dear Doctor,—Upon the receipt of your letter requesting me to get for you Mr. Hope's information and personal knowledge respecting the "Mediterranean wheat," I wrote to that gentleman by the first opportunity, and received his reply on Saturday last, which I take much pleasure to communicate to you. He says he received it first in 1830, from the State of Delaware—it came from up the Mediterranean sea from Turkey. He sows from 1½ to 2 bushels to the acre, and it yields from 10 to 25 bushels per acre—the flour equal to that from the Red wheat, and will produce about the same price in the market. It shouled be sowed from the 5th to the 10th of September; and he never had any injured by the fly, when other wheat in the same field has been destroyed. He has *heard* of the fly injuring it, but believes that it has been from its being mixed with other kinds of wheat, which will occur. He was induced to try it on account of its having been represented to be *fly-proof, of which he is well satisfied.* It was brought to New Castle, Delaware, by a sea captain, whose name Mr. Hope does not recollect. My experience of this wheat has not been as long as Mr. Hope's (having got my seed from him) but so far as I know I agree with him as to his statement. In communicating the above, I do it with the remark, that I do not know how far Mr. Hope would like his name brought before the public. In case you should conclude to publish any statement respecting this wheat, his communication was friendly and personal, and I beg leave to suggest, if you wish to make use of his name, that his consent should first be obtained.

I have part of a field (about 2½ bushels sowing) this season, which looks fine now, and which I commenced sowing the 4th of September, and which I think will test its properties as to its resisting the fly. I mentioned to you my opinion was, that it came from Odessa, a city of Russia, up the Archipelago. Mr. Hope states it to have come from Turkey; the climates I presume were similar.

With esteem and respect, I rest, dear sir,
Your friend and servt.
JAMES PANNELL.

—

I take the responsibility of publishing the above letter without having obtained the consent of either Mr. Hope or Mr. Pannell. From the known intelligence and respectability of both these gentlemen, as farmers and citizens, their testimony will go a great way in settling a controversy which is now in agitation concerning the Mediterranean wheat. Mr. Hope's experience with it is, I presume, of longer standing than that of any farmer in the State of Maryland, and although he and Mr. Pannell, from their modesty, may have no wish to have their names brought before the public, yet I am sure from the interest they both take in diffusing correct information on a subject of such vital importance to the agricultural community, they will readily excuse the liberty I have taken.

Here is a case which shews the great importance of establishing an Agricultural Society in each county. Mr. Hope is a citizen of Hartford county, and not more than twenty-five miles distant from the writer of this communication; yet the latter had not heard till very recently, of his having any knowledge of the Mediterranean wheat. Had the information which he possessed, in regard to its being a *fly-proof wheat*, been known, it would have saved thousands of dollars to the farmers of this county—two years having occurred, since its introduction by him, in which the wheat crop was almost a total failue from that scourge, the Hessian fly.

In regard to the flour-producing properties of this wheat, Mr. Pannell has verbally informed me that he thinks it at least equal to any other. Mr. Richard Webster, an experienced miller, and one of high respectability, has expressed an unequivocal opinion in its favor upon this controverted point. In addition to this I have the testimony of several of my neighbors, which is of the same purport.

I am, very respectfully, yours,
W. L. HORTON.

Wood Lawn, Harford co., Nov. 25, 1843.

RULES WORTH BEING OBSERVED BY FARMERS.—1. Perform every operation in the proper season. 2. Perform every operation in the best manner. 3. Always keep your implements and tools in the best order. 4. Finish one job before you begin another. 5. After finishing a job always return your tools to their proper places. 6. Do not put in a crop too large to cultivate well. 7. Personally attend to every operation, and see that it be effectually done.—*Balt. American.*

From the Southern Planter.

AGRICULTURAL APHORISMS.

As the stalk of corn in the field, so the young man; both must be cultivated or their fruit will be chaffy.

Some men subsist by labor of the body, some by labor of the mind; a combination of both is important to success.

Some men write without thinking, some think without writing; the one is willing and not able, the other able and not willing.

There is no profit without capital. The merchant's capital is his money; the farmer's capital is his manure bank.

Winter time is hard by, and I venture to admonish every farmer to count his cattle, and then his hay stacks, and if the one shall exceed the other, then either sell, eat, give away, or kill the surplus to keep them from dying.

Agriculture is favorable to morals, to health, and to wealth.

Mankind might do without physicians, if they would observe the laws of health; without lawyers, if they would keep their tempers; without soldiers, if they would observe the laws of Christianity; and perhaps without preachers if each would take care of his own conscience: but there is no living without farmers.

ARGUS.

Amherst, October, 1843.

From the Baltimore American.

IMPROVED AGRICULTURE.—At a meeting of the Farmers' Club of New York, last week, the following facts relating to extraordinary results in Agriculture and Horticulture were presented to the notice of the members. We re-publish the statement for the benefit of a numerous list of agricultural subscribers of the American:—

Mr. Pell, of Ulster county, made a statement relative to his experimental farming, from which it appeared that he had found benefit from the use of Oyster shell lime—using 300 bushels per acre. That in addition he had employed 52 bushels of Charcoal per acre. That on this Charcoal dressing he obtained last summer 78 *bushels and* 24 *quarts* of wheat per acre. That he had 20,000 apple trees in full bearing. That in dry weather he had applied lime freely at the roots—found that this preserved the verdure and growth when the neighborhood was much injured by the drought. That he had cut wheat two or three weeks sooner than his neighbors; and when the roots of the straw began to turn brown and when by pressure of the finger and thumb on the grain, its milk would fly out.—That this wheat weighed 64 pounds per bushel. That he sold it for seed for $1 when ordinary wheat was 7s. That he cut clover and housed it on the same day—sprinkling about a bushel of salt over every load. That this clover retained its green color and was preferred by cattle to that saved the old way. That he dipped sponge in ammonia and applied to the worm nests on his trees and banished them completely. That he has sent to market *fvur thousand* barrels of apples, many of which go to London and there sell for nine dollars per barrel. That he employed a man from Vermont to engraft 10,000 apple trees for $150. That this man brought a company of men, two sawed off the proper limbs; two more made the proper incisions (two of them) in the back, two more inserted the grafts, two more applied a compost of wax, tallow and rosin. That out of the 10,000 grafts not one failed.

FOR TETTERS AND RINGWORMS.—Procure the roots of the yellow or narrow leaf dock, bruise them and soak them in good apple vinegar, and rub the tetter or ringworm three times in the day till a cure is effected. This is a certain remedy, except where the nails of the fingers are diseased.

ANOTHER.—Bruised mullen leaves and vinegar constitutes an excellent remedy. It is said to be a sure restorative of the nails, particularly if the patient does not become weary in well doing.

ADVICE TO FARMERS' DAUGHTERS.

A *female* correspondent of the Tennessee Agriculturist, last year wrote several communications under the signature of Lucy, containing much wholesome advice to farmers' wives and daughters, and we find she has again resumed her labors in an address to Farmers' Daughters. Her communications of last year were greatly admired and extensively copied, and we think our own readers will conclude after reading the subjoined, which is the first of her new series, that it is destined to find as much favor with the intelligent as did her former ones.—*Amer. Farmer.*

TO FARMERS' DAUGHTERS.

The desire of information is necessary in order to the acquisition of it, and as books are one of the principal sources from which we derive our most valuable knowledge, I will talk to you about them, and a few other matters this evening. A taste for reading should be cultivated by all young persons. I consider a fondness for useful books one of the greatest blessings. Without this, there are so many hours that pass away heavily and idly, and for which no good account can be rendered in time or eternity.—In bad weather, I have seen young ladies lounge about, not knowing what to do with themselves, because they could not go out to visit or shop.—The case is so much altered, when you can sit down with pleasure to a good book, and heedless whether it rain, or the sun shine, can read on, determining to improve the dark days of life by laying up those stores of knowledge so much needed in after time. You derive pleasure not only from the book, but also from the reflection, I have improved the time. I have learned something I did not know before. It is of great importance that you have the right kind of books. Many young persons read, and it would be better for them if they were ignorant of the alphabet. They read for present excitement, and of course, novels are the only books for which they have an appetite. It is my opinion, you had better not read at all, than acquire a passion for them, for it generally amounts to a passion. Girls who read many novels, lose their common sense and healthy action of mind. They dream over the love sick eloquence of the heroines, the beauty, bravery, and noble bearing of the heroes; all the great events therein related are pondered over, until the common affairs and duties of every day existence, are tasteless and disgusting, and they are thrown aside whenever it is possible, for the favorite novels. This is not always the worst evil resulting from improper reading. The splendid qualities of the heroes are transferred to some living character; it is imagined he has the deep dark and lustrous eye, the wreathing hair, the marble brow, the noble and high born grace of a Thaddeus, a Sir William Wallace, or some other imaginary favorite; and it is all the same whether he be a gambler, a play actor, or a horse thief, she believes it not: reflection is at an end, and the novelist wakes from her dream, to bear her bitter lot in the stern realities of life, without preparation of mind or heart. On the contrary, useful books impart strength and vigor to the mind, discipline it to bear the misfortunes of life, render it more capable of judging the true character of others, and of acting with discretion in all trying situations. Read for instance the life of a Franklin, a Washington, a Miss Hannah More, and you find in every page something to imitate, something to better the heart and life. In Miss M. you see a woman of true feminine grace and dignity, one who learned and taught the art of "growing old gracefully."

If you will read novels, read but few, and those selected by some one upon whose judgment you can depend. Miss Edgeworth, if I might hazard an opinion, is one of the very few whose works may be read with safety and even profit. She has sense, practical every day common sense, that is good for use. She talks about industry, economy, correct principles and actions. She possesses at the same time delicacy and propriety in all things. Better for you to read the pure morality that lives in her writings, than to pore over the passionate effusions of the corrupt Bulwer. He it is, who now writes, and forms the taste of millions, and when he talks of love, how fervently do his tones of tenderness gush forth, as if *he* had a heart to appreciate the holier sentiments of human nature. But while he thus writes, he can treat even with personal violence, the beautiful wife who loved and trusted,—who gave to him the first pure affection of her noble heart; he can separate her from her children, drive her from his home to take refuge with strangers, and even follow her with insult and persecution. But I am digressing. There is another article I will mention. Read but few books, and let your knowledge be accurate. Understand perfectly what you read, it is better to gain two ideas you can appropriate to your own use, than to have a confused idea of fifty things.—One of our great men attributes all the distinction he has gained, to the careful perusal of *one* book. The authors of purest style and most correct sentiments should be studied; while those of an opposite character ought ever to be carefully avoided. You know a woman is generally thought intelligent, if she can talk about a good number of authors she has read. I do not think it is always conclusive evidence. It is oftener a proof her knowledge is superficial.

There are but few of our sex who devote much time to study, in our part of the country at least, and you frequently find that she who has most names at the end of her tongue, has fewest ideas in her head. Some minds of uncommon strength may be improved by the study of many books; where however it is advantageous to one, it is a disadvantage to many others. A feeling of vanity is produced, and the intellect confused, rather than enlightened. Of course I speak of *young* persons. Do not look into books in order to make a show; to know their titles and a few sentences from them. I have seen young persons who would look for an hour or two into Paley, and then talk more of philosophy than others who had studied him thoroughly, and had his ideas on all matters.

Some one writing of this effort at display, says, "you can always see the bottom of the pebbly brook, but the ocean unveils not its richly gemmed carpeting." Miss Beecher, speaking of a young lady who had but *few* books, and had studied them well, mentions that "a person of information in conversing with her would always feel a constant wondering pleasure, to find she had so much more to say of this and that and the other thing than he had expected."

This cannot be said of mere smatterers you know. There are many of you who devour with eagerness, all the fashionable journals of the day; a great part of which consists of pretty love tales. Now, love is an excellent thing in its place, but reading about it all the time is not much benefit. I cannot think you derive much improvement from such studies. They produce a pleasing excitement for the time, but then that time is to all intents and purposes *wasted*. Take care of the minutes, and the hours and days will take care of themselves.

There are papers in our country you may read, and improve from the perusal, and they are those devoted to Agriculture. You may say, what have I to do with Agriculture? You have much or will have, in the course of your future life. They will teach you how to cultivate the gardens you intend to have, when you go house keeping; how to manage houshold affairs with the most ease and to the best advantage, how to do a hundred and fifty other things. A number of you will marry young doctors, lawyers, preachers, merchants, with soft white hands, who know nothing beyond their professions, and if you can learn something beforehand, and teach them common sense about going to work, and earning their living by the sweat of their brow, as the Lord intended them to do, it will add more to your own comfort than you have any idea of. After the first romance of love is over, you will want all those things that grow in the earth, and out of the earth, and you cannot gain them without a good degree of knowledge and a great deal of hard work. My maxim is, learn every thing you can, from darning socks, to decorating cows. Put it all down in your mind, or in a book. You will need it sometime or other.

To mention these Agricultural papers again, I would not be deprived of the information I gain from them, for all the love tales in the country. The Boston Cultivator, for instance, contains much that is pleasing and useful. There is always something addressed to the ladies, that makes it a welcome guest. The Yankee Farmer, thinks it one of the most proper things in life that girls learn about the "soft soap of domestic economy," while young. The American Agriculturist has a little of most all matters that are good. The American Farmer and the Cultivator will teach not only you, but your fathers, a good deal they do not know. There is a host of other Farmers and Planters, and Ploughboys and Cultivators, that I have not now time to write about, but they are all valuable for their information on business we have to attend to every day, month and year. I have but one objection to some of them, and it is, that they do not say *quite* enough for the benefit of the Ladies. One reason may be given for this, the ladies say very little to them. I have written till I am tired, I expect you will be tired reading, and will tax you no longer.

Lucy.

PROPER DEPTH FOR SEED.

Various experiments have been tried to determine the proper depth at which seeds should be put. The following is the result of an experiment with maize or Indian corn:

That which was planted at the depth of				
No. 1.	1 inch,	came up in	8½	days.
2.	1½	" "	9½	"
3.	2	" "	10	"
4.	2½	" "	11½	"
5.	3	" "	12	"
6.	3½	" "	13	"
7.	4	" "	13½	"
8.	4½	" "	—	"
9.	5	" "	—	"
10.	5½	" "	17½	"
11.	6	" "	—	"

The Nos. 8, 9, 11, were dug up after 22 days, and it was found that No. 8 had an inch more to grow to reach the surface of the earth. Nos. 9 and 11 had just sprouted, but were short, and three inches below the surface. No. 10 came up in 17½ days, but the tender leaf remained only 6 days green, and then withered. There is no experiment which shows more clearly the advantage of a shallow planting in a soil not too loose, and trodden down, than this. The more shallow the seed was covered with earth, the more rapidly the sprout made its appearance, and the stronger afterwards was the stalk. The deeper the seed lay, the longer it remained before it came to the surface. Four inches was too deep for the maize, and must, therefore, be for yet smaller grain kernels.

Petri gives an experiment made on rye, with the following results. The first column shows the depth at which the seed was put; the second, the number of days that elapsed before it appeared above ground; the third, the number of plants that came up:

Depth.	*Appeared.*	*No. Plants.*
1-2 inch.	11 days.	7-8
1 "	12 "	all.
2 "	18 "	7-8
3 "	20 "	6-8
4 "	21 "	4-8
5 "	22 "	3-8
6 "	23 "	1-8

The root-stalks forms itself always next below the surface of the ground, and if we place the grain deep, it must first put out its sprouts to the surface, and form its side branches in a nearer connexion with the air. We never find

that the slacker roots are ranged from below to above, but the contrary.

From the experiments of Ugazy, who tried seventy-six with different grains, it is clear that shallow sowing, if the seed is only so far covered as to sprout, and the germ is protected from immediate contact with the air, is preferable to laying the seed deep, because it springs up quicker, and acquires a stronger growth, and has hardier plants.—*Burger's Economy of Farming.*

THE ECONOMY OF AGRICULTURE.

Liberality constitutes the economy of agriculture, and perhaps it is the solitary human occupation, to which the adage, 'the more we give the more we shall receive,' can be justly applied. Liberality to the earth in manuring and culture is the fountain of its bounty to us. Liberality to laborers and working animals is the fountain of their profit. Liberality to domestic brutes is the fountain of manure. The good work of a strong team causes a product beyond the hard work of a weak one, after deducting the additional expense of feeding it; and it saves moreover half the labor of the driver, sunk in following a bad one. Liberality in warm houses, produces health, strength and comfort; preserves the lives of a multitude of domestic animals; causes all animals to thrive on less food; and secures from damage all kinds of crops. And liberality in the utensils of husbandry, saves labor to a vast extent, by providing the proper tools for doing the work both well and expeditiously.

Foresight is another item in the economy of agriculture. It consists in preparing work for all weather, and doing work in proper weather, and at proper times. The climate of the United States makes the first easy, and the second less difficult than in most countries. Ruinous violations of this important rule are yet frequent from temper and impatience. Nothing is more common than a persistence in ploughing, making hay, cutting wheat, and other works, when a small delay might have escaped a great loss, and the labor employed to destroy, would have been employed to save. Crops of all kinds are often planted or sown at improper periods or unseasonably, in relation to the state of the weather, to their detriment or destruction, from the want of an arrangement of the work on a farm, calculated for doing every species of it precisely at the periods and in the seasons most likely to enhance its profit.—*"Arator's" Essays.*

Tools, and Tool Sheds.—There should be attached to every farm house, a *Tool Shed*, capable of containing all the implements required on the farm, during winter, and at other seasons when not in actual use. The expense of such a convenience is a mere trifle, compared with its advantages, and would be more than economising in a few years. We have often been surprised on beholding the ploughs, carts, ox-wheels, harrows, and wheelbarrows, exposed in the yard of a farmer, who was too "saving" to pay a couple of dollars a year for a paper, and who perhaps would look upon the annual disbursement for such a purpose, as a drain upon his exchequer not "to be endured." And yet, he could complacently behold his tools rending and rusting in an exposed situation without even thinking of the loss, or the saving that might be effected simply by providing a substantial protection from the airs and rains.—*Maine Cultivator.*

Excerpts.—Brass and metal kettles should never be used in the preparation of preserves. Iron ware lined with porcelain or tin, is much preferable, and not subject to the verdigris which acids produce on the others.

Give hens chalk or egg-shells with their food, and they will lay double as many eggs as before.

A farmer should never keep more cattle than he can keep in good order. An animal in high condition the first of December, is already half wintered.

From the American Agriculturist.

TOPPING COTTON—MARL.

Sumpter District, S. C., Nov. 4, 1843.

In those excellent matter-of-fact articles on the cultivation of cotton, which have appeared in the late numbers of your paper, by Dr. Philips of Mississippi, and which, by the way, are the best I have ever seen on the subject, I do not recollect that he has touched upon the subject of topping cotton. I have made one experiment in this, and was pleased with the result.—Some planters north of us, I understand, have also tried this method, and find the cotton is not so apt to shed, as when it is not topped, especially in wet seasons. Ordinarily we reckon the first week in August the best time for topping; but this, of course, will depend upon the season, and the forwardness of the crop—for sometimes it must be earlier, and sometimes later.

I tried the effects of what I suppose to be marl, on a small spot in one of my fields, say about one acre. The marl I judge to be of poor quality, yet can not say, positively, as I have no analysis of it. I dug it out in January last, and spread it broadcast, at the rate of 30 loads to the acre, as large as an ordinary pair of mules would carry. It seemed to pulverize well, exposed to the severe frost of last winter, and I ploughed it in deeper than I usually plough, and harrowed the land well. The result is, I shall get full one-third if not one half more cotton off this piece than any other part of the field, which more than pays me for the trouble.

I need not say that we read the articles on manures in the Agriculturist with much interest; for many of us are beginning to learn that it is not only easier and better, but even *cheaper* to renovate our old lands, than emigrate to a new country and bring new lands into cultivation. C. McD.

Good Fruit.—That it is just as easy to have good fruit as poor, is a truth that every farmer should remember; and this, if acted on, will be found not only easy but profitable. If the fruit orchard is deficient in numbers or varieties, lose no time in correcting the evil; and the best way is to apply to some experienced nurseryman for the kinds and qualities most desired. A few good fruit trees of each desired variety, is far better than great numbers with inferior fruit. A *succession* of good fruits is indespensable.—The varieties of summer, autumn, and winter, should follow so as to leave no interval. Enlarge your list of different kinds of fruit, rather than your varieties of the same.—*Ab. Cult.*

Poultry Houses.—If you wish your hens to lay through the winter, have their houses cleaned out thoroughly. Empty the nests of all filth, have them scraped inside and out, and then whitewashed. Place contiguous to your henhouse, under roof, a peck or two of lime, a bushel of gravel, and a load of sand or ashes, so that they can daily have access to these substances. Give them chopped fresh meat once a week, or oftener, and feed them regularly twice a day with grain and potatoes—always feeding them near the hen-house, so as to attach them to it. Keep their nests at all times well supplied with clean hay, and a few chalk imitation eggs in each: if you have no chalk, clay will answer every purpose, provided you whiten the eggs by whitewashing them. See, too, that your fowls get water regularly. If you follow this advice, you'll find that your hens will lay nearly as many eggs in winter as they do in summer.—*Amer. Farmer.*

Preserving Manure.—If you have no barn cellar or other shelter for your manure that has accumulated in the barn-yards, pile it in a heap or heaps, and cover it all over, sides as well as top, with a muck of any kind or turf. This will prevent the escape of much of its enriching properties which would otherwise by lost. —*New England Farmer.*

From the Southern Planter.

POUDRETTE.

Mr. Editor—In your last number of the Planter you have requested information of the results of experiments tried with poudrette.—You will probably recollect, having furnished me with two barrels of the article, with which I experimented as follows: Upon English peas, contrasted with hen-coop manure; upon potatoes, contrasted with stable manure; upon onions, in *union* with hen-coop manure, and in contrast with it; upon grape vines; and upon corn in contrast with the soil; and upon early York cabbage. In every case its superiority was manifest, except with the cabbage; the peas were decidedly superior. The vines of the potato, (which I have not yet taken up) were full two-thirds better than the others. The onions were as fine as they could well be—but I could not ascertain with accuracy the difference. Its effects upon the grape vines was astonishing, and has apparently completely restored them to health and vigor. But its most perceptible superiority was upon the *corn*, the difference being fully as *three* to *one*. Why it did not appear to benefit the cabbage, I cannot conjecture. If I may take the liberty of expressing an opinion, I should say that I consider it the most valuable manure I have ever used; but I am not as yet prepared to say whether its superiority will justify the difference in price between it and other good manures. I am rather inclined to think it will not; but this opinion is not based upon a thorough knowledge of its virtues, which (it must be admitted) are very great. I purpose trying other experiments with it, and I hope to settle that point, at least, to my own satisfaction. You shall know the result. Whilst upon the subject of manure, may I ask you whether you do not think an individual, fully competent to the task, might do a good business by going round and analyzing the soil upon different farms? or has agricultural chemistry yet sufficiently diffused itself among the farmers to render them sufficiently alive to its importance?—For myself, I should be much gratified to have an accurate analysis of my land, and would be willing to pay a fair compensation for it.

Respectfully,

John B. Garland.

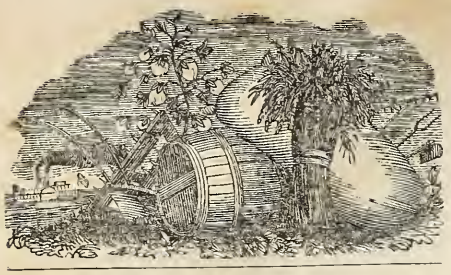
Fredericksburg, Sept. 25, 1843.

We are much obliged to Dr. Garland for his report upon Poudrette, and should be pleased to learn whether his results have been verified by the experiments of others.

Churning Butter.—Every good housewife knows that at times, for some peculiar causes, (most generally extra sourness or bitterners of the cream,) much difficulty is experienced in making the cream into butter. A lady writer in the Indiana Farmer, recommends the following course in such cases. We have (says the Western Farmer,) for years used soda or saleratus for the same purpose, and found them usually successful:—

"I wish to inform my sister butter-makers, of the means I used, which so successfully removed the difficulty. I churned, perhaps, three hours, to no purpose, and then tried to think of something that I had read in the Indiana Farmer, or some other periodical. I could not remember precisely, but I recollected the reason stated, was the cream being too sour. I then thought of soda, (pearlash, I presume, would do as well,) and dissolved a large teaspoonful in a pint of warm water, and as I poured it in, churning at the same time, it changed in a moment, and gradually formed into a beautiful solid lump of sweet butter."

Flour for Burns.—J. Marshall, Esq., surgeon, recommends, in a communication in the London medical Journal, the employment of wheat flour as an application to burns. This mild substance, he says, is doubtless pre-eminent to all others hitherto used, by imparting immediate cure to the inflamed and irritated surface.



WEDNESDAY, DECEMBER 20, 1843.

SPECIAL NOTICE.

According to the terms, the Cultivator is published on the CASH SYSTEM, and all subscriptions terminate with the volume. No paper, therefore, will be sent to the address of any gentleman until his subscription is paid. The absolute necessity for the adoption of such a policy on our part is so apparent to every man of common sense, that we need not enter into any defence of our course. We cannot afford to send a collector over the country to collect b lls of *one dollar* each, and shall not attempt such a piece of folly. Those who desire to subscribe can hand their DOLLARS to the Post Masters, and request him to order copies for them, which he can do free of any charge for postage.

☞All subscriptions must commence with the volume.

TO THE SUBSCRIBERS OF THE SOUTHERN CULTIVATOR.

The present number closes the first volume of the "Southern Cultivator," and although we cannot flatter ourself that we have given satisfaction to all, yet we indulge the belief that no one has carefully read the volume without profit; and we shall, therefore, enter upon the second volume with increased confidence in the success of the enterprisc. If we have accomplished no other good, we certainly have, to some extent, excited among a portion of our planters, a greater fondness for agricultural literature, and infused into a few a disposition to profit by the experience and practical operations of those who are far in advance of us in the science of agriculture. This we consider an important point gained; one, too, which we think will contribute greatly to the accomplishment of our great object—the introduction among southern planters of a more enlightened system of culture.

In concluding these brief remarks, we beg leave to refer our patrons to the terms which may be found on the last page of this number, and to assure them that the ensuing volume shall equal, in every respect, the one now closed; and that it may be superior, we shall contribute all our efforts, and hope to be more generally sustained in those efforts by the planters themselves than we have heretofore been. We make this last remark in no spirit of complaint, for, indeed, we feel gratified to those who have contributed to enrich our columns with their views. The writing for a paper was, however, a new thing to most, if not all, of them, and they naturally enough felt some delicacy in appearing before the public. We are, however, much pleased to observe that this feeling is giving way before the lights of truth and a sense of duty, and our planters are now beginning to feel and acknowledge the necessity of giving to each other, through the medium of the "Southern Cultivator," the results of their experience. We therefore confidently hope, that our second volume will number a much larger list of contributors than the first could possibly enumerate.

AGRICULTURAL SOCIETY IN OGLETHORPE.

The proceedings of the meeting at Bowling Green, for the purpose of forming an Agricultural Society, were received too late for publication in our last, they are, however, contained in this number; and, in giving place to them, we should be doing injustice to our own feelings towards a portion of the citizens of our native county, not to welcome them most cordially as colaborers in the great cause of agriculture, and the consequent improvement and promotion of the general happiness of the laboring class.—The cause of Agriculture is eminently philanthropic, and should enlist in its behalf, the energies of the benevolent of every class of society. What higher or nobler purpose could engage the philanthropist, than the amelioration of the condition of the great mass of his fellow creatures. And by what means can he hope to secure, more certainly, the greatest good to the greatest number, than by introducing an improved system of agriculture? We invoke our friends throughout the country to contemplate this subject with reference to the happy influence it will exert upon society, apart from the more sordid consideration of gain, in which it appeals in equally strong and forcible terms, and then determine whether or not your duty to your fellow man does not require you, as good citizens, to unite and form Agricultural Societies and Clubs in every county and neighborhood.

COMMUNICATIONS.

BOWLING GREEN, Oglethorpe county, November 25, 1843.

Agreeable to previous notice, a portion of the citizens of Oglethorpe county assembled at Bowling Green, in said county, on Friday, the 24th of November, for the purpose of organizing and forming an association to be known by the name of the Bowling Green Agricultural Society.

On motion of Ferdinand Phinizy, Mr. William Lumpkin was called to the Chair, and Jas. H. McWhorter appointed secretary.

After the meeting was organized, and its objects made known by the chair, Dr. Thomas Moody moved, that we now proceed to elect, by ballot, a President and three Vice Presidents, together with a Secretary and a Treasurer, to preside over this Society for the next twelve months.

It appeared that John W. Moody was duly elected President, and William Lumpkin 1st, Giles Young 2d, and Thomas Howard 3d Vice President, William Lewis, Secretary, and William Beasly, Treasurer.

The President, on taking the chair, addressed the Society in a brief but very appropriate address, in which he urged the importance of the agricultural interests, and the great necessity for an improved and enlightened system of culture. He concluded by offering a Constitution and bye-laws to govern the body, which were adopted.

On motion of Jacob Phinizy, Jr.,

Resolved, That the proceedings of this meeting be signed by the President and Secretary, and a copy furnished to the editor of the Southern Cultivator for publication.

The Society then adjourned to meet on the third Saturday in December.

JOHN W. MOODY, President.
WM. LEWIS, Sec'y.

GWINNETT CO., October, 1843.

Mr. Jones—Being a reader of the Southern Cultivator, I have noticed several articles on the subject of the manufacture of cotton bagging from cotton, and having some practical knowledge on the subject, I avail myself of the invitation given in your paper, to give the result to the public through its columns, with the hope of contributing something to render the planters more independent, and add to their comfort.

During the late war with England, when bagging was scarce and very high—one dollar per yard—I purchased a sley made for the express purpose of weaving bagging, forty-two inches wide, sixteen "*hier.*" At that time I grew flax, and made several pieces of bagging, as good as the imported article, which I sold for one dollar a yard. Twelve or thirteen years ago, I put up a screw for packing cotton, since which I have made all my bagging, rope and twine of cotton, which was spun upon a common wheel, and wove in a common loom in the old sley. The warp should be sufficiently stout to work two threads in a reed, and the filling coarse enough to keep the cloth the full width of the sley. Every girl that can draw a thread can spin the filling, and if the warp and filling are sufficiently stout, the bagging will be of as good quality as may be desired. I make mine to weigh from 1¼ to 1¾ pounds per yard, and in four and a half yards I pack 330 to 350 pounds of cotton. I always save the inferior cotton to make the bagging and rope, and my bales look as neat as any bales I see in market, and generally, I believe, command as good a price as any, according to the quality of the staple. None need fear of success if the thread be sufficiently stout, and the sley be of the right kind. I therefore think that almost all planters, particularly small planters, may supply themselves with an excellent article of bagging and twine of their own make.

There is another article I find greatly to my advantage to manufacture at home, which is wove in the same sley and loom—I mean blankets for servants. If made heavy and well wove, they will be as warm as, and much more durable, than the imported article. They may be made of any convenient size, and if the filling be slack twisted and neatly carded after being wove, the blanket wil do no discredit to the bed of a gentleman and his lady. My family have made their blankets for many years, and those wives and daughters who feel a desire to

excel in the manufacture of their carpeting, will find such a sley a great auxiliary, and so far as the home manufacture of these articles can contribute to our independence and comfort, we can accomplish it, and I hope that our wives and daughters have both industry and patriotism sufficient to make the effort, provided they are seconded in their exertions by their husbands and fathers.

Yours, respectfully,

ANSELM ANTHONY.

To the Editors of the Louisville Journal:

Gentlemen,—Having noticed in your paper a call on the farmers to send you their experience of this year in the different branches of farming and of the improvement of the soil, I will proceed to give you mine in the raising and ploughing under of broadcast corn. We had a field of thirty-seven acres which had previously and the year before been cultivated in corn, and the soil of which required renovating; and, believing nothing could be sown which would speedily accomplish the end proposed than broadcast corn, I proceeded accordingly. The field, previously to being sown, had not been broken up and the old stalks still remained upon the ground.

About the latter part of April I commenced sowing. Upon thirty acres I sowed two bushels of corn per acre, and upon the remaining seven three bushels per acre, and ploughed the whole under, old stalks and all, two inches deep.

It came up and all grew equally until about two feet high, when a marked difference began to present itself, and at the age of maturity that which was sown thick had scarce reached five feet high, whilst the other had attained the height of seven or eight feet. Hence we see, for two reasons, a decided advantage in favor of thin sowing: first, because it requires less corn; and, secondly, your stocks will grow both larger and taller, and from my own observation I may add that less than two bushels per acre would perhaps be advantageous. And now comes the ploughing under. Finding it impossible, with the aid of a log-chain reaching from the beam of the plough to the end of the double-tree, to turn it under as well as desired, I determined to seek some other mode, and for that purpose knew of nothing better than the roller, which I accordingly procured, and commenced rolling it down by lands of suitable width for the plough to follow. The roller is of such weight that when drawn by two horses it will mash the stalks down flat with the ground, and I can unhesitatingly say that stalks, even ten or twelve feet high, may in this way be completely turned under to the depth of four inches without injury to the horses.

Were my only object the rapid improvement of the soil, within the shortest space of time, I would not seek further or better means than first sowing down thick with rye, which I would plough under just before the time of ripening, to prevent its seeding the ground, and upon which I would sow one bushel and a half of corn per acre; thus, in the same season, ploughing under a heavy coat of rye and corn, which, in the short space of twelve months, will equal if not surpass any benefit which can be derived from clover in two years.

Though last, not least, another important advantage to be taken into consideration is, that by this double process your land is less exposed to the deteriorating effect of the sun's rays, when a rye crop is ploughed under in June and corn sowed broadcast, than when with corn alone you would be compelled, if sown early to plough under in August, and consequently your land would be left exposed to the scorching influence of an autumnal sun.

October 12, 1843.

☞ Virtue maketh men on earth famous, in their graves illustrious, and in Heaven immortal.

From the Albany Cultivator.

VALUABLE TABLE.

Messrs. Gaylord & Tucker:—A few days ago, I was much in want of some dry measures of capacity, as I have often been before; but this circumstance had never led me till then to think of the vast numbers of house keepers, especially farmers, who suffer inconvenience from the same cause; in fact, I do not believe that I should err in rating them at ninety-nine in every hundred. Why they continue to do so, they themselves can best tell; but it occurred to me that I might render them an acceptable service by publishing a list of boxes in a square form, which I made out for my own use, to contain the following quantities: a barrel, half barrel, bushel, half bushel, peck, half peck, gallon, half gallon, and quart. The square shape was preferred, as being far easier, both to make and to calculate, and the list was immediately sent to my friend Mr. Ruffin, editor of the Farmer's Register. But, as many read your Cultivator who never see his paper, I now send the same statement to you, that you may publish it, if you think it may be useful. A similar table is not to be found in any book that I have ever seen; although it is perfectly obvious to every body that it is much wanted. The advantage of buyers especially, would be considerable; for they could always ascertain whether they received their proper quantity of any thing sold by dry measure, if they would only carry the table in their memories, or on a memorandum, together with a small rule in their pockets.

—

TABLE.

A box 24 inches long by 16 wide, and 28 inches deep, will contain a barrel, or 10,725 cubic inches.

A box 24 inches long by 16 wide, and 14 inches deep, will contain a half barrel, or 5,376 cubic inches.

A box 16 inches long by 16 8-10 wide, and 8 inches deep, will contain a bushel, or 2,150 4-10 cubic inches.

A box 12 inches long by 11 2-10 wide, and 8 inches deep, will contain one peck, or 537 6-10 cubic inches.

A box 8 inches long by 8 wide, and 4 2-10 deep, will contain a half peck, or 268 8-10 cubic inches.

A box 7 inches long by 4 wide, and 4 8-10 inches deep, will contain a half gallon, or 134 4-10 cubic inches.

A box 4 inches long by 4 wide, and 4 2-10 inches deep, will contain one quart, or 67 2-10 cubic inches.

These measures all come within a small fraction of a cubic inch of being perfectly accurate, as near, indeed, as any measures of capacity have ever yet been made for common use; the difficulty of making them with absolute exactness has never yet been overcome.

In addition, gentlemen, to the motive already stated for making this communication to you, I offer it as some small return for the instruction and entertainment which I have already received from your highly useful paper; and beg you to accept my very sincere wishes for its future prosperity.

I remain, gentlemen, very respectfully, your obedient servant, JAMES M. GARNET.

From the Southern Planter.

GALLS AND GULLIES.

Mr. Editor.—From the wretched system of cultivation in many parts of Virginia, the farms present an uncomely aspect from innumerable galls and gullies. Experience has taught me that these may be stopped without any very great labor. Every one in the field intended for corn, ought to be stopped. It is the more necessary, because observation will soon teach one that when the hill sides are deeply ploughed and kept well cultivated, that but little superfluous water passes down the gullies; and hence there is less danger of their washing out after having been filled up. The best time for the operation is as soon as the land thaws after a severe freeze; or during some wet time when it would not be proper to work in the fields. I commence by running a two horse plough up one side and down the other, so as to throw the dirt into the gully. The horse next the gully should be coupled to the other by a long cord, and that to the trace of the other below the attachment of the backband. This precaution will be found necessary, so that if he fall in he may not pull his fellow after him. The gully is a convenient deposit for any thing that may lie in the way, such as logs, stumps, rocks, brush, &c., but they are by no means essential for the success of the operation.

It is generally necessary to have some hands with hoes, mattocks, &c. as there are many places that the plough cannot reach in consequence of the zigzag form of the gully, until some digging be done. Also many have forks, or prongs, so that the ploughing cannot be done until a crossing place be made near the main gully.—I am in favor of continuing the operation only until the place becomes such that a single horse plough can cross with ease, and then leave the balance to the gradual washings of after years. When I have arrived at this stage I cover the whole place well with manure and sow small grain, (or peas,) and turn in the manure and small grain together, and then sow a mixture of different kinds of grass seeds with plaster of Paris, and cover the whole with straw.—In a few days the grain will put up through the straw and hold it so closely to the earth that the most washing rain will not remove it. I prefer a mixture of red clover, herdsgrass and greensward seeds.

In the subsequent cultivation of the field the gullies should remain untouched by the plough or hoe; and in a little time the grass will form such a sward as to catch a sufficiency of dirt, during the washing of rains, to render the original gully nearly level.

Those who have not tried this plan may be incredulous; but such as doubt, may examine my farm and see for themselves, that gullies thus treated, have seldom been injured by washing rains. It is often the case that less time will be required to stop a gully than would be lost in turning the plough during the cultivation of the crop.

Every farmer ought to get clear of his gullies in four or five years, according to the number of shifts he may have on his farm.

I can say but little of the efficacy of hill side ditches to prevent gullies from washing out, but do not doubt their usefulness. I should have tried them if my professional engagements would have permitted me.

If the foregoing shall not benefit any one, it may serve to elicit information from some person more competent to instruct.

R. D. PALMER.

October 28, 1843.

HINTS TO YOUNG FARMERS.

CULTURE OF THE MIND.—You know well that one piece of land, a garden for instance, yields vastly more than another piece of ground of equal natural fertility. And you know equally well, that one man abounds more in knowledge and usefulness, than another to whom nature has been alike bountiful. It is culture—it is the industry and perseverance of man exerted in one case and not in the other, that produces the marked contrast in both. The cultivator is sure to be rewarded in his harvests, for the care and labor which he bestows upon the soil—and the reward is no less certain to him who devotes his leisure hours to the culture of the mind.—The soil administers to our annual wants.—Knowledge not only greatly assists in supplying these wants, but is the primary source of intellectual wealth, which dollars alone cannot give; and when consorted with good habits, tends to refine, elevate and distinguish men above their fellows. Talent is not hereditary.—You will see on looking around, that some of the most distinguished men of our country have sprung from the humblest parentage. They

are indebted for the distinction, to the culture which they themselves bestowed upon their minds. The road to usefulness and honorable distinction is equally open to you, and the time has arrived when you must decide, whether you will compete for the noble prize.

If you wish to prosper in your business—to know and profit by the improvements of the age, cultivate your mind; for this is the great labor-saving machine. If you wish to see your children intelligent, thriving and respected, teach them, by example, to cultivate the mind. If you would be useful to your friends, and merit the confidence and esteem of your neighbors, seek early to qualify yourself for the duties of social life, by the culture of the mind, if you aspire to intellectual enjoyments which flow from the study of the material world—from the order, harmony and beauty, which meets us in every walk, in the manifold and wonderful works of the creator, cultivate the mind. In fine, if you would prosper in your business, your family, and in society, cultivate your mind.

But knowledge is not always wisdom, and therefore, be as scrupulous in regard to your studies, as you are in regard to the seed which you deposit in the soil. You will reap whatever you sow, and the mind is as liable to be cumbered with weeds as the soil. Read, therefore, whatever tends to instruct you in your business, to establish you in good habits, and to fit you for the responsible duties of life. Acquaint yourselves with the inventions and improvements of modern art. Make yourselves acquainted with the general facts of science, with the wondrous laws by which the Almighty governs all these around us; and with the endless illustration of laws, in the world and all its parts. The facts of natural history will afford abundant matter for agreeable and useful knowledge. The plants, the animals, the minerals, the soils of your country—the changes of the seasons—the make and composition of all that surrounds you duly observed, and made the subjects of reading, of conversation, of reflection, will at once store your mind, and raise your ideas of the wisdom and goodness of Him who formed you such as you are. Temperance, self-government, moderation, avoidance of all abuse of the body, are written in the very make of the body itself. And it will hence plainly appear, that when our maker says, abstain from all impurity, he does but say, "Do thyself no harm."

Who aims at excellence, will be above mediocrity; who aims at mediocrity, will fall short of it.

We copy, says the South Western Farmer, from our scrap book, two recipes on the subject of curing bacon. The first for hams, we know not how we came by, but would be a little fearful that the ley would eat up the skin, having observed it eaten, when packed away in ashes not well leached.

Hams.----Take 12 lbs. salt, 1 lb. saltpetre, 1 gallon molasses----with this mixture, rub the hams well and pack away as carefully as is possible in a cask, to remain one week. Then with 1 bushel of ashes make a ley, put the hams in it, to remain 3 weeks. Smoke and pack away in tan bark. This for 12 hams.

Bacon.----The gentleman who gave the following to us, some 10 years ago, was somewhat advanced in life, a citizen of Ohio, and one of those who had boated down the Mississippi, in those broad horns, and walked through "the wilderness," as all this country was then called. We copy his directions, word for word. To ensure good bacon, it must be good corn fed pork, cold before salted, salt rubbed in hard, and let lie for 24 hours. Prepare you pickle, by taking 1 oz. saltpetre, 1 oz. pearl ash, 2 quarts molasses, enough salt to fully saturate water sufficient to cover 200 lbs pork in a barrel; the pork may be packed close in a barrel with a little salt, then pour on the pickle----cold, when any scum rises remove it. Let the pork remain 5 to 6 weeks, then smoke well, then dip into strong ley, and return it into pickle---bugs will never trou-

MR. BOTTS' ADDRESS.

The following notice, in which we fully concur, of the address of Mr. C. T. Botts, editor of the "Southern Planter," before the Henrico Agricultural Society of Virginia, reminds us of a duty, heretofore omitted, of acknowledging the courtesy of the author in sending us a copy.

"We have perused the address with great pleasure. It takes a rapid view of agriculture, its importance as a science, the deep interest which the South has in it, and the bearing which it has upon our Republican institutions. The author urges upon the society to redouble their exertions in the good cause in which they have enlisted, and we doubt not his suggestions will meet with a hearty response from the members of the Henrico Society."

Dignity of Labor.—In many portions of Europe, to labor is dishonorable. In this countsy, it is honorable, for here an idle man is a nuisance. An author says: "The American motto is industry. Labor is honorable—idleness is dishhnorable; and I care not whether it is the labor of the head or of the hands, for they mutually aid each other. Let me, however, exhort those who are devoted to intellectual pursuits, to cherish on their part an exalted and just conception of the dignity and value of manual labor, and to make that opinion known in their works, and seen in their actions."

GARDEN AND FIELD SEED.

A GENERAL assortment of fresh and genuine GARDEN and FIELD SEED, among which are the following:

Red and White Clover,
Blue and Green Grass,
Rye and Orchard do.,
Timothy and Herds do.,
Millet and Lucerne do.,
Seed Corn of every valuable variety,
Seed Wheat,
Buckwheat and Potato Oats,

Kept constantly on hand by the subscriber, all of which are offered for sale at very moderate prices. All orders, by mail or otherwise, executed with neatness and despatch.

WM. HAINES, Jr.,
No. 232 Broad street, Augusta, Ga.
August 30. 18–tf

TURNEP SEED.

A SUPPLY of the following varieties of fresh TURNEP SEED just received, viz:

Yellow Sweedish or Ruta Baga, very fine for stock,
Large Globe Turnep, } Fine
" White Flat do. } for
" Hanover or White Ruta Baga do } table
" Norfolk do. } use.

For sale in quantities to suit purchasers, by

SOUTHERN CULTIVATOR.

VOL. II. AUGUSTA, GA., JANUARY 10, 1844. No. 1.

COMMUNICATIONS.

SANFORDVILLE, PUTNAM COUNTY, January 1, 1844.

Mr. Editer—As the time for ditching hill-sides is fast approaching, (the proper time being from the first of February to the first of April, when the earth is soft to any desirable depth,) I shall undertake to comply with my promise to your correspondent of Newnan, who desires that I should give my mode of ditching, with all the practical information I am possessed of on that subject. The subject is one of so much importance to planters and farmers of any hilly country, (particularly one of thin soil,) that I am inclined to shrink from my promise, fearing I shall fail to do it that justice it so much demands. But if I shall be able to give any instructions to the readers of your paper, on a subject that they should be so deeply interested in, as that of ditching their hill-sides to prevent what soil we have left from washing off, I shall consider the time consumed in writing, as well as from other considerations, well spent. Let me assure your correspondent, as well as all the readers of your paper, that all the practical information I am in possession of, in every branch of husbandry, both in and out doors, appertaining to our domestic concerns as planters and farmers, is at their service; although I am ready to acknowledge that I am like most other planters in the management of my plantation affairs, viz: I know a great deal better how things should be, than I have them in general.

I shall not pretend to claim the honor of conceiving an idea which has, and will, confer such lasting benefits on the planting and farming interest of our country as that of ditching hill-sides; that belongs to some one of greater forethought than myself. But so far as I know, I am the first that introduced it in this section of the State, and the first to put it in practice in any thing like a scientific manner; though my date goes no farther back than ten years. I brought the theory, as well as a little practice, with me when I moved from Virginia in 1832.

The first ditching I done in this State, was a small hill-side, of 4 or 5 acres, then partly in gullies, and had it not been improved, and the former mode of cultivation been persevered in, before this the little soil left would have been gone, and it would now be worthless. But I have the pleasure to inform you, that it is now almost entirely clear of gullies, and some parts of it are more productive than when I first ditched it. This, however, is owing to several sprinklings of manure it has been treated to.

I have ditched more or less every spring for the last ten years, and yet have more to do the coming one than I have ever done in any one season. This is partly owing to an addition to my farm—which is all quite broken. Indeed, there are but few acres, if they were all together, that would not be benefited by ditching.

The spirit of ditching is considerably on the increase in this section; but I am sorry to see so little of what is done, well done. We often hear it remarked about matters pertaining to our plantation affairs, that any thing well done, was worth more than being half done twice. This is strictly true in reference to ditching, which, once thoroughly done, is of more benefit than a dozen times partially or half done. I have seen the bad effects, and have felt the smart, for half doing things, and in nothing more forcibly (that I now recollect) than that of ditching. A half made ditch will do for dry weather, or for light rains, but when such rains as we frequently have in this latitude fall, those who have half made ditches will find them, on examination after the rain, destroyed by the water that had collected in them, and the land worse off, in many places, than if there had never been a ditch.

Perhaps my friend of Newnan will become impatient at reading this communication before he comes to the descriptive part, or that giving my plan of ditching. I will, therefore, make that the next thing for his consideration, with the hope that he will receive some benefit, of which I have no doubt, if he will but practice upon my suggestions.

In the first place, I have a level made similar to the one described by Mr. Hunt in the Southern Cultivator some time last spring, perhaps in April, only mine strides but 10 feet, with a cross piece about half way from the top to the ground. One of the size of mine is more handy than one that strides fifteen feet. The fall given to a ditch is two inches every ten feet; though in locating a ditch, one should not be governed by his plum line at every stride, as it is advisable, in some instances, to cut the ditch deeper in some places than others, so as to form it in the best shape that the location will admit of, and to prevent sudden curves. I have my ditches cut from 15 to 20 inches wide at the top, and at least 12 inches deep, with a square bottom of at least 12 inches wide; throwing all the dirt on the lower side, to form a bank on the margin of the ditch. This is done by first marking off the place where the ditch is to be made, by a boy with a hoe, making a chop at every stride of the level; then with a good plow and plowman, the horse being led on the marks for the first furrow; after that running 4 or 5 other furrows as deep as possible; all the loose dirt is then removed with hoes, and the horse and plow is again used for a second plowing, and continue the process until the ditch be made the requisite depth. Some of my ditches are not more than 30 or 40 feet apart; but these are on hill-sides that are very steep. Where hill-sides are of a gradual descent, a ditch for every 30 or 40 yards, and, in some instances, 40 or 50 yards, is sufficient. But as regards the distance between the ditches, the person who locates them must exercise his judgment in that particular, and should not be too fearful of getting them too near together. When rows are to be run off for planting corn or cotton, there must be judgment exercised in deciding on which side the short rows, if it is likely there will be any, which is most always the case between the ditches, whether the situation of the land between the ditches requires that the short rows be thrown above or below a ditch; always commence running off rows parallel with one ditch or the other. Mr. Hunt, in his communication on the subject, directed that the rows should be run off parallel with each ditch, so as to throw the short rows, if any, in the centre. I think this is a bad idea, for if there should be many short rows, and there frequently are, and sometimes at some distance from where the ditches empty their water, in such cases, in a great fall of rain, those short rows would catch a grea deal of water, which would collect in a body and make its escape, forming a gully till it got to a ditch or some outlet. Ditches, after being made, must be carefully attended to and kept well cleaned out; nor should the grass and weeds be permitted to grow up and fall in them so as to obstruct the passage of water, and, in some cases, do serious damage to the land below. The cleaning out of ditches, after being well made, is but a light job. If much litter, dirt, &c. collect in them, run up and down with a plow to losen every thing that should be taken out; it is then easily removed with the hoe.

One of the difficulties in ditching, is to obtain a suitable situation to empty the ditches, to course the water out of the field or plantation. When there is a branch running through a field, that is a suitable place for that purpose; in other cases, a field that has a long hollow across it, perhaps a gully already made, that is a place to empty in; and sometimes it is best to make a ditch to empty others in; and it is best, in most cases, to commence laying off a ditch where the water is intended to be emptied, and where this ditch is long, it requires to be made more sub-

stantial, to enable it to carry the increased body of water. For this and one other reason, when I have a field to ditch, the situation of which will admit of it, I run the ditches from the highest part of the field to each side, if there is any situation that will admit of their being emptied. This plan gives a shorter and safer ditch, and by leaving a narrow space on the departure of each ditch to its side, affords a pass way for a cart, &c., for hauling.

The opinion prevails among some planters, that land will naturally improve after being well ditched, and that there will be no more washing; both of which I think are erroneous. I have yet to see the piece of land that will improve, under constant cropping, without the aid of manure; and as regards washing on our steep hill-sides, when a heavy rain falls, there will be certainly some little cross washes on certain situations; for instance, when there is a little rise or sink on the land between the ditches, either of these will hinder the gradual drain of the water that collects in the rows that cross those places, which will cause a little cross wash to the first ditch below. In all such places as these, when I sow my wheat or oats, I have corn-stalks gathered and thrown, and as the plow passes over them, make the plowman shake the dirt off his plow on them. And wheat and oats will grow in such places as well as any where else.

I do not extend the heads of my ditches out to my fences by some 8 or 10 feet, unless circumstances require it; that much is left for the convenience of a cart-way.

I do most earnestly recommend all those who intend to ditch their hill-sides, to do so before the gullies form, as after gullies are once made it requires much labor to fill them up, and then in nine cases out of ten, the ground is left lower about them than it was before any wash had taken place. All such sinks will catch the drain of water from each row that crosses them, and cause a cross wash to the ditch below. I would not, however, discourage those who wish to ditch their hill-sides that are already in gullies, but advise them to proceed forthwith, and when gullies are of much size, make a secure dam wherever a ditch crosses one—one at least safe enough to keep the water in the ditch—then fill up the gullies between the ditches with any thing that is most convenient.

I have failed, Mr. Editor, as I expected I should at the commencement of this communication, to do this subject that justice which it so much merits. I have not made the descriptive part as plain and as easy to understand as I wished to have done; the ideas given are not as connected as they should have been; but I will make no other apology than that I have done as well as my limited ability would afford. Allow me, in conclusion, to say to those who wish to ditch their hill-sides, not to wait for any more information one the subject; that one day's practice will teach them more than a half dozen communications.

I saw in the Cultivator some time back, that there was an Agricultural Society formed in Morgan county, and that they had prescribed certain premiums, to be awarded some time this year. The best sample of hill-side ditching was to receive (if I am not mistaken,) the highest premium. I then thought, and do yet consider that object one of the best selections for a prize that I have known. When that object is properly carried into effect, it will be of more benefit to the planters of this section of country, than any fat ox, horse or hog, whose owners have received their $5 for their skill in raising them.

Yours respectfully,

JOHN FARRAR.

BRYAN COUNTY, January 1, 1844.

Gentlemen—I have been a subscriber to the Cultivator for the past year, and have just forwarded to you, through the Post Master, the amount of subscription for another copy, the receipt of which you will acknowledge by sending me the first number for 1844.

How does it happen that I have never, to my recollection, seen in your paper a single paragraph in relation to Sea Island Cotton? Can it be that you have so few patrons on the seaboard, or that they send you no communications? I have waited patiently myself for such, and perhaps others have done the same, from the same motive. Our lands yield in value a large portion of our exports, and it is a matter of considerable interest to our small number at east, to give and receive information on that subject; and although I am by no means an adept in the culture of the long staple, I *might* occasionally throw out a hint which might be extended and improved upon by others more capable than myself. But to the object of this communication: We have large portions of land on the main, adjoining our salt-water rivers and inlets, such as live oak flats, &c., which produce what is termed, in our fraternity, "*Blue Cotton*," from, I presume, the blueish cast of the plant. These lands are very rich, and produce fine crops of corn, but so far as I am acquainted, there has been no remedy applied for "Blue Cotton," which they almost invariably produce. By this term we mean such cotton as comes up and grows very luxuriantly, without any fruit, reaching at times the height of 8 or 10 feet, having large leaves, with crimped edges, and of a deep lead color; so much so that a spot in the field may be recognised as far as the plant can be distinguished. At other times, depending perhaps on a very wet season, the plant, after growing several feet, and bearing well, sheds all its fruit and becomes "*blue.*"

This is a serious difficulty with our strong lands, and I hope among your many readers, some one may be able to suggest a remedy for he evil. It has been generally supposed among us, that land containing a large quantity of iron would have this effect—why, I know not; but if such is the fact, it appears to me that lime would be a good application, and it is my intention to try it. The chemical action of lime on the organic substances of which our strong low flats and swamps contain a great deal, is very considerable, and this is not only in reference to vegetable remains, but it acts with equal energy upon the dead and living animal matter. Its operation, therefore, *may* effect a change in the production of the plant. Besides, if the soil contains sulphate of iron, the iron is decomposed by the lime, which, uniting with its sulphuric acid, forms the sulphate of lime, which is commonly called gypsum, and which is universally admitted to be a great fertilizer of the soil. Now the question is, will this chemical process have the effect of changing those matters in the soil which cause our cotton to *turn blue.* Experience, of course, will be our surest guide on this subject, but it would be deeply interesting to read the views of some of your learned correspondents in relation to it.

Respectfully, &c.,

AGRICOLA.

P. S. I have been using, for some time, the plow in the cultivation of the Sea Island cotton with advantage, and I intend, this year, further to facilitate my work by the side-harrow and the cultivator. Be good enough to say, in your next number, if I can obtain the latter implement in Augusta, whose make, at what cost, and whether they will answer between beds 4½ feet apart. They ought to be made so as to be moved for a greater or less distance.

Mr. Editor—The following table, showing the vitality of seeds, I have copied from Loudon's Gardening, and as it may be of service to your agricultural readers, as well as to the venders of seeds, I send it to you for publication.

"7027. *The latest period at which the seeds most generally in demand may be expected to grow freely*, are the following:

Cabbage tribe, 4 years.

Leguminous Culinary Vegetables, 1 year.

Esculent Roots.—Beet 10 years; turnep 4; carrot 1; parsnep 1; radish 2; salsify 2; skirret 4; scorzonera 2.

Spinaceous Plants.—Spinach 4 years; white beet 10; Orache 1; purslane 2; herb patience 1.

Aliaceous Plants, 2 years.

Asparaginous Plants.—Asparagus 4 years; sea-kale 3; artichoke 3; cardoon 2; alisanders and thistles 2; rampion 2.

Acetarious Plants, in general, 2 years; lettuce 3; endive 4; burnet 6; mustard 4; taragon 4; sorrel 7; celery 10.

Pot-herbs and Garnishing Plants, in general, 2 years; but parsley will grow at 6; dill and fennel 5; chervil 6; marigold 3; borage 4.

Sweet Herbs, generally, 2 years; but rue and rosemary 3; ann hyssop 6.

Plants used in tarts, &c., generally 2 years; but the rheubarb only 1; and gourd pompion, &c. 10.

Herbaceous Fruits.—The cucumber and melon 10 or more years; love-apple, capsicum tribe and egg plant, 2.

Annual and biennial flower seeds, generally 2 years; but some grow with difficulty the second year; they are seldom kept by seedmen longer than one year.

Perennial flower seeds, the same.

Tree Seeds.—Stones 2 years; and some, as the haw, 3; but they are in general of very doubtful success the second year; acorns will scarcely grow the second year; elm, poplar, and willow seeds, not at all."—p. 1237. W. P.

EGGS.—A correspondent says—"Eggs that produce the male chicken may be distinguished from those that produce the female, by their being longer and more pointed at the ends than those of the female; which are more rounded at the ends.

"People who raise chickens for the market will do well to select those eggs which produce the male chicken to set their hens with, as the males will be larger and of more value than the females."—*Planter.*

From the American Farmer.

MARLING AND LIMING.

We subjoin a letter upon the subject of *marling*, addressed by Gov. Hammond to the Agricultural Society of the State of South Carolina. It details a series of experiments made by him in the use of *marl* on his land, in different quantities, per acre, varying from 100 to 300 bushels, and their results fairly tested and compared by other lands not marled. The results are natural, and accord precisely with our preconceived, and often expressed sentiments, in respect to the use of lime and marl. The experiments of Gov. Hammond prove, that though lime may be *bread*, it is *not bread and meat* too: that worn out lands require *animal* and *vegetable* substances as well as mineral: that *large* doses of lime or marl upon soils deprived of their organic remains, or vegetable food, by a long course of exhausting cropping, are injurious, and will impair, rather than benefit such soils for present purposes: that *small* doses are better than *large* ones, under any circumstances; and that the *frequent* or periodical application of lime, in small quantites, is the policy indicated alike by economy and nature. Lands that are rich in undecomposed vegetable matter, of themselves, or where it may be applied in large quantities, can bear, and will be benefitted by, any *reasonable* quantity of lime or marl; but in its application the party must exercise a sound, discriminating judgment, or he may do more harm than good. We will here advance an opinion which we have often attempted to impress upon our readers. It is this—that whenever they are about to improve a worn out field with either *lime* or *marl*, and it may not be convenient to apply stable or barn-yard manure, that they should prepare the ground for the reception of the calcareous matter, by previously growing thereon, and turning under, at least two crops of buckwheat, which should be so turned under just when the plants are *first beginning to bloom*. *Lime*, we consider, in some form, as being *indispensable* to every soil; but as it is far from being the only food upon which plants feed, those other kinds in which, for variety sake, they may delight, must also be provided for them.

No man is disposed to go further than we are in the *rational* praise of the wonderful effects of calcareous matter as an improver of the soil—we believe that no *permanent* improvement can be effected in an exhausted soil without it—and that by a judicious use of it and nutritive manures, that many soils may be made better than they were in their virgin state—but with all our preconceived opinions in its favor, we *cannot* get our consent to adopt the opinion, that lime alone is sufficient to restore fertility to worn out land.

And we will here seize the occasion to impress these truths upon our readers—that *twenty five bushels* per acre, of lime, for all present purposes, is better than a hundred—that upon poor, exhausted land, more never should be applied, at one time—and that these quantities should be repeated every four years, until one hundred shall have been applied; and then, that five bushels a year will be enough.

Thursday Evening, Nov. 20, 1843.

The Proceedings of the last meeting were read, and a letter from his Excellency Jas. H. Hammond was read, as follows:

Columbia, November 17, 1843.

Dear Sir—In fiulfilment of my promise made last November, I again communicate to you the results of my experiment in *Marling*. The year has been so unfavorable for cotton, and my crop has fallen so far below the promise of July, that if I had not left some unmarled acres for a test, I should, as no doubt has often been done in other experiments, have come to the conclusion that all my labor had been in vain; and that, in fact, the marl had seriously injured my land. The truth, however, is very far to the contrary, and I now think that but for the marl I should have made no crop at all.

I planted this year seven hundred acres of marled land: of which six hundred and eighty were in cotton, the remainder in pindars and potatoes, of which no accurate account was kept. The cotton turned out about as much per acre in the whole, as the average of the same land for the last ten crops. But believing this year to have been at least 20 per cent more unfavorable than an average one, I attribute that much increase to the effect of the marl.

In my last communication I stated that I had selected four acres of good mulatto land, and four others of very light sandy soil, one acre of which in each selection was left unmarled, and the others marled with one, two and three hundred bushels respectively. For the purpose of showing the difference between the most favorable and the most unfavorable seasons I have known for cotton, as well as to indicate the progressive comparative influence of the marl, I subjoin the results of the last, as well as the present year, on these expertmental acres.

Experiment No. 1—Mulatto Land—1842.

Unmarled acre,			1111 lbs seed cotton.				
100 bushels	do	816	do	dec't	265 lbs	22.8	per cent
200	do	do 1003	do	do	180	9.7	do
300	do	do 1318	do	inc'se	207	17.7	do

Same Land, 1843.

Unmarled acre,			493 lbs seed cotton.				
100 bushels	do	654	do	inc'se	161 lbs	32.6	per cent
200	do	do 759	do	do	266	53.9	do
300	do	do 841	do	do	348	70	do

As I remarked last year, the acres with one and two hundred bushels of marl are decidedly inferior in quality to the other two. The unmarled acre and that with 300 bushels, are as nearly equal as any two on the plantation. It is hardly necessary to say, that these acres lying side by side, were all planted on the same day, and cultivated in precisely the same manner.

The experimental acres of the thin light land were planted last year in corn. All the marled acres produced better than the unmarled, but I will not repeat the statement, as it does not afford an accurate comparison with the cotton crop of this year, of which the following is the result.

Experiment No. 2—very light, sandy soil—1843.

Unmarled acre,			361 lbs seed cotton.				
100 bushels	do	451	do	inc'se	90 lbs	24.9	per cent
200	do	do 384	do	do	23	6.3	do
300	do	do 173	do	dec'r	188	52.	do

The land, being very old, is bare of vegetable matter for marl to act on, to which more than the texture of the soil, inferior as it is, I attribute the failure of any great improvement from it. I make the statement however because it is valuable in many respects. It shows the danger of heavy marling on worn land without previous rest or manure. The acre with three hundred bushels has been destroyed. There is one rich spot, the bottom of a small basin in the centre of it, which produced nearly all the cotton gathered. On the rest of it the weed mostly died as soon as it came up—one hundred proves a better quantity than two hundred bushels, and perhaps a little less would have been still better on this soil—at least to begin with. All the lightest land in the fields marled with two hundred bushels was evidently injured and now requires help. I anticipated this effect from what I saw last year, and reduced the quantity to one hundred and fifty bushels on all the land then marled. I have reduced it now to one hundred bushels and shall hereafter marl at that rate. I prefer to go over it again after I have finished all, and give it what it may prove itself able to bear after resting once or thrice.

The crop of this year has satisfied me perfectly that cotton will mature at least a fortnight earlier on marled than on unmarled land.

Another unexpected effect of marl it may be worth while to state. I commenced in the spring of 1842 to put it in my stable, pretty freely, for the purpose of improving my manure. I did not think of its having any material effect on the health of the mules. But I have had but little sickness among them, and have not lost one since, while previously I lost on the average four annually, and never, in any year, less than two. I attribute this change in a great measure to the absorption of noxious gases by the marl. I am now marling as actively as heretofore, and I esteem it so beneficial that I have this summer marled a field of over two hundred acres, the average haul to which is three miles from my landing: and being tolerably fresh land that has rested this year, and was sowed in oats last year, which were not cut but grazed down after ripening, I have put on one hundred and fifty bushels.

The fields on which my experimental acres are will rest next year. I shall not therefore be able to continue my report to you. Since, however, the valuable labors of Mr. Ruffin in the State have given a decided impulse to marling, I presume that all who are in reach of marl will at least experiment for themselves; and it will be of no consequence that I should longer communicate my experience. I am very truly and respectfully your obedient servant,

J. A. Hammon.

Hon. Whitemarsh B. Searbrook.

From the Southern Planter.

SALT A PREVENTIVE OF SMUT.

Sir—In perusing the pages of your excellent journal, I find salt recommended as a fertilizer; although my experience with this mineral is very limited, still such as it is, I have concluded to give it to you.

A few years since my crop of wheat was so badly injured by the smut, that I determined I would not use it for seed, and I, therefore, purchased from a neighbor a few bushels that was clean and good. I found, however, that I had not near enough to finish my crop, and having heard that salt sowed with wheat would prevent the smut, I resolved to make the experiment.—Accordingly I took my smutty wheat and washed it, and mixed with it while it was yet wet, about a quart of salt to each half bushel, and with it finished sowing my crop.

When I harvested the crop, I found the wheat purchased of my neighbor much injured by the smut, but my salted wheat was entirely free from this disease, and so superior in quantity and quality, that I believe if I had let alone my neighbor's *clean* wheat, and sowed my whole crop of my own smutty wheat, thus prepared, I should have made one hundred bushels more than I did.

In the spring of 1842 I tried a similar experiment on a few bushels of smooth chaff spring wheat, which was much affected with the smut. I washed and mixed as above, about a quart to the half bushel, and sowed it by the side of the same wheat without this preparation. My salted wheat grew about six inches higher than the other, and yielded me twenty bushels to one seeded, whilst the other did not yield half that quantity.

Respectfully, your obedient servant,

A. Lee.

From the Farmers' Journal.

CABBAGE HEADS FROM STUMPS.

Friend Cole—I do not know all that your Boston gardeners are up to, but I do know, that if cabbage stumps of any variety are set out in the spring in good order, that one, two, three or even four good sound heads will grow on them—and this they will do year after year, until they die by accident.

They are managed in the following manner: When the upper, *narrow leaved* ones, which would bear seed, are carefully rubbed off, and likewise all the lower, *round leaved* ones, which will form heads except the number the strength of the stump and soil are capable of bringing to perfection.

At our cattle show, last week, Mr. John Drew presented several such stumps, with one to four heads of low Dutch cabbage on each, which have borne for three years. He sets them out in earth in the cellar in autumn, cuts off the heads when required for use, and places them pretty thick in the garden in spring. The labor is trifling, the cut worm gives no trouble, and the crop sure and abundant.

James Bates.

AGRICULTURAL ADDRESS.

The finest Agricultural address of the year was made by Dr. Daniel Lee, at Buffalo. We select the following extract, because it will be read with as much interest by every intelligent resident of the town as by those engaged in agriculture. After showing that plants derive thier chief nourishment from the carbonic gas and ammoniacal gas in the atmosphere, and that these gases are thrown in the atmosphere in inexhaustible quantities by the decomposition of animal and vegetable matter and by breathing, he proceeds thus:—*Louisville Jour.*

GENTLEMEN:—I have in this glass, water taken from a well near my residence in this city, such as is used by my family and others. You see it is quite clear, although I suppose it holds in solution among other earthly ingredients, a portion of lime. Every time a person breathes, he expels from his lungs carbonic acid, which, as I have told you, is the appropriate food of plants. I will now breathe into this water and see what, if any, effect will be produced. You see the water is changed to a milky whiteness.

You will recollect the question to be solved was: how to seize upon the carbonic acid expelled from organic beings, in order to change it back again into new plants and animals.—By understanding the laws of chemical affinity, I have seized upon a valuable earthy manure, lime, which robbed the soil of an indispensable element when it left it; being dissolved in rain water, in its passage from the surface of the ground through the earth to the well, from whence it was taken. On the other hand I have *petrified* in this white powder, which is the carbonate of lime, a portion of my brain, nerves, muscles, fat, bones, &c., which may be converted into wheat, corn, and potatoes in a day; or may be kept without change, a thousand years.

The peculiar value of this artificially formed carbonate of lime over the chrystalized carbonate that forms about one-eight part of the earth's crust, is this: that the vital action of the roots of plants will decompose an impalpable power like this sooner than fragments of lime rocks in the soil. Hence slaked lime is more valuable as a manure than unburned limestone. No sooner, however, is this carbonate decomposed by the action of a living growing plant, than the free lime, whose carbon has gone to build up a vegetable, takes up another, and still another portion of carbonic acid. At night, plants consume no food, or very little, but digest what they have imbibed during the day.

The chemical affinity between lime and carbonic acid accumulates vegetable food at the roots of plants during their sleep at night, and when the light of day awakens their vegetable appetite, the lime that was free at sun down has prepared for them a good breakfast, for aught we know, may be, as in this instance, a portion of a human eye, or a human heart. When, however, the lime is deprived of its carbonic acid, it is soluble, as you have seen, in water; which, sinking deep into the earth or running off from its surface, growing plants are robbed of this source of food. The only remedy for this is to apply a little lime evenly over your grass, and your cultivated fields; and to apply it often, if your wheat or grass fail to answer your just expectations. True economy in feeding plants, like the feeding of domestic animals, consists in giving them just what they will eat up clean, and no more. Much of the excess of food will be dissolved in water, and carried beyond the reach of your growing crops. Still more will escape into the air, by the combined action of heat, light, and electricity.

I have stated to you that most plants require in addition to water and carbon, a portion of nitrogen. This also comes from a gaseous substance in the atmosphere. Although nitrogen forms the largest element in the air, (79 per cent,) yet it has been pretty well settled that plants do not obtain their nitrogen by decomposing common air, but derive it from ammonia, which is furnished to the atmosphere in great abundance by a world of decomposing vegetable and animals. It is the ammonia that escapes from putrifying substances that causes their offensive smell. Now, again, comes up the practical question: how are we to collect this highly volatile gas, and transform it at the cheapest rate, into wheat, beans, cheese, and wool, of which it is an important element? Rain water has a strong affinity for ammonia; which is a compound of 14 parts of nitrogen and 3 of hydrogen. Water at 50 degrees will absorb 650 times its bulk of this vegetable food. Every rain, then, brings considerable quantities of it to the ground. It is the ammonia in snow that makes it valuable as a manure; and it is the ammonia in rain water that causes it to purify in some degree like an animal substance, when water is permitted to stand in warm weather in a close vessel above ground. The first fall of a rain after a long drought is much the richest in this gas. Being extremely volatile it escapes into the air again after a warm shower much quicker than water evaporates. What then will aid the cultivator of plants, and seize this volatile ammonia, as lime does carbonic acid, and hold it permanently about their roots, in such a shape that it will feed them all they need, and no more? For an excess of this stimulating alkali, like an excess of salt in our food, will destroy life instead of supporting it.

Common Charcoal is the cheapest, and therefore the best material to apply to cultivated fields for this purpose. It will absorb 90 times its bulk of ammonia, and will give it out slowly to the vital attraction of the roots of plants. Most of you know that charcoal will correct the taint in meat; will purify rain water in a suitable cistern, so as to render it the purest water for culinary purposes. Such charcoal should be often renewed in filtering cisterns, and when saturated with ammonia, is an extremely valuable manure. The liberal application of this well known substance to the wheat fields in France, has mainly, in connection with the use of lime, added within the last ten years 100,000,000 bushels to the annual crop of wheat grown in that kingdom. The charcoal should be sown in May, at the rate of 75 bushels per acre, well pulverised. This subject is one of vast practical importance. By studying the science of agriculture, you may grow fifty bushels of good wheat on any acre of your land, I have good reason to believe, every year, bating of course extreme casualties.

You all know that, a single kernel of wheat, will, sometimes, when its fecundity is highly stimulated, send up 20 stalks, and that each stalk will bear a head containing 100 kernels. Here is a yield of 2,000 fold. Nature then has rendered it practicable to harvest 2,000 bushels of good wheat from one bushel of seed. The most sceptical among you will not deny that 2,000 kernels have been produced from one kernel, and that the same natural causes that produce such a result in one instance, will ever operate, at all times, under like circumstances, in the same manner. Hence it is but reasonable to say that nature is quite as willing to produce 50 bushels of good wheat on an acre of ground every year, mark me, *if her laws be obeyed*, as she is to grow fifty bushels of weeds every year on the same ground.

We cannot forbear annexing the following remarks on the management of cattle, and the preservation of health:

GENTLEMEN:—I was brought up to the severe labor of cultivating a poor soil. I have sown many a ton of plaster with my own hand; and many a moonshiny night have I followed the plough, that an ox-team might escape the heat of June, in breaking up large summer fallows. I mention these personal incidents as an apology for claiming to know something of the *practice*, as well as a little of the *science* of rural economy.

Permit, then, a practical agriculturist, who has devoted the best energies of his mind for years to the study of agricultural chemistry, vegetable and animal physiology, to say to those of you who are wool-growers, that by keeping the animal warm in winter, cool in summer, and quiet throughout the year, by stimulating with the elements of wool, the organs that secrete this valuable covering of the sheep, it is practicable to clip six pounds of wool as the product from the same amount and value of raw material that now yield you but three pounds. To accomplish this important result, this physiological change in the products of this living machine, you must *quiet the action* of the lungs. These expel from the system every moment, night and day, a needless quantity of animal food, which, under more favorable and other circumstances, might have been converted into wool, tallow and muscle. Mark me. There is a positive loss, a needless throwing away of 20 to 50 per cent of the food in wintering all domestic animals, which is literally burned up by nature, in this cold climate, to keep their blood, and the whole animal, some 40 or 80 degrees warmer than the temperature of the air with which they are surrounded. It is not merely the hay, oats and corn in domestic animals, and the bread and meat in man, which are consumed like the animal oil in a lamp, to warm the system, that are lost; but, by inhaling a cold and dense atmosphere, and bringing a larger amount of oxygen gas into the lungs, and through them into the blood, than is needed, inflammations are generated, ending in consumptions, alike in man and beast. An animal is an electrical battery or machine. It is practicable, so to excite the organs that form fat in a pig, in a positive degree; and to so quiet all the other organs of the animal by a kind of negative electricity, that the animal shall transform nearly all of its food that can be converted into fat, into that well known substance. The same remarks will hold true, in a good degree, when applied to the secretion of milk in cows, and the secretion of wool in the capillary organs of the sheep. On the other hand, it is quite as easy to make a pig secrete an enormous amount of bone, and an enormous amount of gristle: to have a hide as thick as a board, a nose like a plow beam, ears like sides of sole leather, and legs like an elephant!

Of all the complicated machinery in warm-blooded animals, the action of the lungs is the most important. It governs the action of the heart and that of the digestive organs. And the action of the lungs is governed, in a good degree, by the condensation from cold, and expansion from heat of the air taken into them by respiration. The condensation and expansion ever varies the quantity of oxygen that passes thro' the lungs into the circulating blood. Hence it is, that in cold climates, and in cold seasons of the year, this excess of oxygen excites inflammatory diseases. Hence it is, that in warm climates and in warm seasons of the year, when the *minimum* of oxygen is taken into the system, less carbonic gas is expelled from the lungs, and the excess of carbon in the food, being the principal element of bile as well as fat, stimulates the liver—an important organ, and the antagonist of the lungs—to a copious and undue secretion of bile. Thus it is that the human race—and domestic animals partake of the same injuries in a less degree—are evermore afflicted with bilious diseases in summer, and inflammatory complaints in winter.

As the preservation of health is a matter that deeply concerns us all, and living, as we do, in a climate subject to sudden and extreme changes in temperature, I have thought a few remarks upon the prevention of disease, would not be unacceptable to those that I have the honor to address.

In addition to keeping the body warmly clad in winter, it is important to keep the blood well supplied with carbon, which will combine with the excess of oxygen taken into the lungs by inhaling condensed air, and thereby prevent its chemical attack upon the living tissues of the peculiarly exposed lungs. This supply of carbon in the blood can be secured by eating meat, and nutritious vegetable food, far more of which

are needed in cold than in warm weather. Consumption is the consuming, the slow combustion of the tissues of the lungs by the chemical action of oxygen gas, concentrated or condensed by cold. Hence by fleeing from our northern winters to a mild climate, where only about one-half the quantity of oxygen—it being rarified by heat—is taken into the lungs at each respiration, consumptive persons often recover. On the other hand, persons living in warm climates in summer, and indulging too freely in animal and other carbonaceous food, and inhaling a rarified atmosphere, are afflicted with an excess of carbon, or with bilious affections. They come north to a condensed oxygenous atmosphere to regain their health, and generally find it. Living sparingly in summer, and eating sub-acid fruits that flourish most in warm climates, and in warm seasons, and contain little carbon and much oxygen, is the preventive of bilious diseases."

From the Chronicle and Sentinel.

AGRICULTURAL IMPROVEMENT.

The following letter, addressed to the Editor of the "Southern Cultivator," manifests such a commendable spirit, and abounds in such sound, practical views, in relation to this important subject, that we take the responsibility, without the consent of the author, of laying it before our readers, and commending it to the attentive perusal of those farmers and planters, (and there are not a few of them in the South,) who are so wise in their own conceit, as to believe that no man can instruct them in any thing about farming.

In our intercourse with planters, the remark is frequently made, *"nobody can tell me anything about farming,"*—a remark which always excites our commiseration for its self-conceited and misguided author. With such men, the progress of improvement is hopeless, until they shall have witnessed its effects upon the farms and in the domestic economy of their neighbors—then they will break through the manacles in which their ignorance has so long shrouded them.

Plains of Dura, Ga., December 8th, 1843.

Mr. Editor:—A few days since, your paper, the "Southern Cultivator," devoted to the improvement of Southern Agriculture, fell into my hands. I was really glad to see such a work commenced at the South, believing, as I do, that such journals are not only necessary to throw light upon the subject by adding the experience of the most skilful planters to our own, but it begets a spirit of rivalship—industry is thereby encouraged, and our system of domestic economy, (if we have any,) is improved.—Without industry and economy, no farmer can succeed in business; and with it, none can fail to supply himself with all the necessaries of life. But, Mr. Editor, we have so long been accustomed to plant after the manner of our ancestors, that I fear the habit with some of us has become confirmed, notwithstanding our much diminished crops and our once fertile, but now washed and exhausted, fields, daily admonish us that some system of improvement is not only absolutely necessary, but must be adopted, or we must seek another home in the "far west." I have, however, concluded to adopt the former, and intend to try my hand in the way of improvement: I have, therefore, determined to become a subscriber to your paper, and have paid the postmaster at this place one dollar for the first volume, which will be remitted to you as soon as the numbers are received. I have been a constant reader of the Albany Cultivator for a few years, and have gathered much valuable information from it; but, upon the whole, I think it throws but little light on Southern Agriculture, as our climate, soil and productions, as well as our domestic institutions, are entirely different from those of the North. There, most of the grasses are cultivated and plowed into the soil, or converted into manure in some way: thus they have a never failing source for fertilizing their lands.

But, are we to infer from this that Georgia has no means of reclaiming her worn out soil? I think not. Bounteous Heaven has every where dispensed its blessings with an even hand. In every country and clime, where man derives his support from the cultivation of the soil, the means of rendering that soil fertile, are within the compass of his power. We are, indeed, not only behind the age, but behind the north, in developing our resources; yet, we are not without them. Let the Southern farmer but try his crab grass for green sward, and I think he will have no reason to complain for the want of the northern grasses for that purpose.

But, Mr. Editor, I did not intend, in this letter, "to argue the point," (as one of my neighbors says,) or advance opinions of my own, but to let you know I wished your paper, that I might get the opinions of the best practical farmers of the State.

Yours, respectfully,

GEO. R. HARPER.

From the Prairie Farmer.

REMEDY FOR HOLLOW HORN, &c.

BY A FARMER.

Having read in your July number an article headed "Remedy for the Hollow Horn," and finding the theory therein contained so contrary to the practice I have been used to, I concluded I would give my views on the subject. For about 30 years my father kept a dairy of from 20 to 40 cows in the city of New York. During the last ten years of the time, (say from the time I was twelve years old,) I began to observe and judge for myself. The last four years of the next ten years of my life I kept a small dairy myself; and for the last ten years I have been a farmer in this vicinity.

For the hollow horn we always used from one to two table spoonsful of spirits of turpentine, poured into the hollow on top of the head between the horns;* and cutting off enough of the end of the tail to bleed,† which may be done by turning the long hair upwards and cutting off a quarter of an inch or less. I have known some persons split the tail, (and cut out what they called the wolf in the tail, which I believe is all a phantom,) put in salt, and bind it up: all the good effect is by bleeding—therefore the less wound the better. I suppose soot and salt may be good. I know salt given plentifully to cattle to be good in Illinois. On the Atlantic coast cattle will not lick salt, though during the winter season we gave salt twice a week with their food. I never knew my father to bore the horns until he had first tried the spirits of turpentine and bleeding, and then bored the horns on the under side only; and only on the top when the holes on the under side could not be kept from closing up with matter. I have heard him say he never lost but one cow with the hollow horn, whilst his neighbors who were engaged in the same business lost many. His rule was, and my practice has been, when a cow brute was observed with a sunken eye and dry nose, (which are the sure signs of the hollow horn,) to put on the spirits of turpentine and bleed at the tail, and have had unvaried success. The greatest difficulty is in not beginning in time. Cattle that have been hard wintered are very apt to have the hollow horn in the spring. It is a common practice with me if cattle do not look well nor thrive in the spring, to use the above remedy. The signs of the hollow horn are, in addition to the sunken eye and the dry nose, the appearance (from feeling) of one or more joints of the back bone being decayed and gone—also a joint near the end of the tail, which of itself is no disease, but the effect of the hollow horn. I never saw a brute have the hollow horn but without all those symptoms, but have seen them in the first stages with only the first two.

[*In the year 1836, on the authority of an experienced farmer, we recommended spirits of turpentine not only as a cure, but as a *preventive* also of the hollow horn—and since then, from personal experience, we do know that it will effect both the one and the other. If a table spoonful of spirits of turpentine be placed in the cup or cavity in the rear of the horns once a month during winter, it will prevent the disease.

†Bleeding is doubtless good; though we have seen a cure effected by the use of the turpentine alone. But if bleeding be necessary, its effects would prove equally salutary if the blood was taken from the neck, which would prevent the disfiguring the cow by shortening of her tail.—*American Farmer.*]

From the Michigan Farmer.

IMPORTANT FACTS FOR FARMERS.

Mr. Editor—I wish to make known through your paper some facts which I think will be of some service to the farmers of Michigan.

Amasa Andrews, Esq. of this town, harvested sixty acres of wheat, this season, while it was so green and unripe, that every farmer in the neighborhood thought, and did not hesitate to declare him mad. He commenced cutting in ten days before any others had begun. The berry, when cut, was soft, and in that state known as being in the "milk." He has now threshed it; and being somewhat curious to learn the result of so novel a proceeding, I to-day went, in company with Mr. Andrews, to the mill and examined the wheat, and found it plump, with a peculiar transparency of the berry which I never before saw—which is to be attributed to the very thin coating of the bran. We weighed some, and found it weighed just sixty-three pounds to the measured bushel; and the experienced one informed me that it made *more flour* and *less bran* than any wheat he ever saw.

Now the above facts are worth knowing, from several considerations. By cutting so early no wheat is shelled and lost, and the harvesting season can be lengthened out, so as not to make it necessary to work so hard or produce a scarcity of hands; besides, the wheat is beyond a doubt better and will make more and better flour.

Yours truly,

N. B. Eldridge, M. D.

Commendable Industry.—We were handed, a few days ago, the following statement of reward of enterprise, which we take pleasure in publishing; not only because it is a remarkable product, but that others may emulate this example of industry. It is as follows:

"Two school boys, sons of Mr. —— Cook, living on the Tombigbee River, raised, on 1¾ acres of land, 5,869 pounds of cotton. They attended school five days in the week, traveling some 3½ miles morning and evening. They worked before going to and after returning from school, and on Saturdays. They are reported as having been afflicted with the chills part of the time. Their names are James and Stephen Cook."

If we were a member of the Agricultural Society, the names of these youths should be presented to the Executive Committee for a premium at its next Fair.—*Eutaw Whig.*

GREEN CORN-STALKS MAKE RICH BUTTER.

At a late meeting of the Farmers' Club in New York, Mr. Morris, of Morrisania, stated that he kept a dairy of a hundred and twenty-six cows to supply the N. York market with milk. That he feeds them on green corn—he sows his corn broadcast—and says it makes better and richer milk than any other feed he has used, and there can be no doubt that it produces more provender, by the use, than any other vegetable.—Mr. Morris' plan coincides exactly with our notion. So much saccharine matter as corn stalks yield, must make rich milk.—*Farmers' Gaz.*

From the Chronicle and Sentinel.

GREAT YIELD OF CORN.

We publish below, says the Louisville Journal, an account of the manner of cultivating an acre of corn, by George W. Williams, of Bourbon county, Kentucky, with a certificate of a committee of the Bourbon County Agricultural Society, appointed to measure the corn and the land. We like this method of doing things of this kind. To learn only that a man grew a certain amount of corn per acre is extremely unsatisfactory. It is of no use to the community and often excites suspicion of imposition.—But we should always have the manner of culture along with a well authenticat'd statement of the amount of produce and the measure of the land.

In a private letter to us, Mr. Williams states that he considered the yield of this acre a failure, on account of wind and blight, and he expects to hear of much larger crops. As to his oat crop, he says:

"I make no report of oats. It was so much blown down, that I did not think it worth while to have it measured in the way directed. My overseer, however, did measure it, and, to my astonishment, reported 49 bushels; many bushels were left on the ground."

September 27, 1843.

GENTLEMEN:—The Bourbon County Agricultural Society have appointed you to measure an acre of corn cultivated by me, with the view of forwarding the result to the Jefferson Agricultural Society, and I am required to give to you, first, a detailed account of the mode of its cultivation, describing the soil and whole treatment from the fall of 1842 to the gathering of the crop." This I proceed to do in as concise a manner as I can. The acre was inclosed about the 1st of September, 1842; is in a square, and includes land, one half of which had been exhausted by long previous cultivation in corn and other crops, and, when inclosed, was such land as, I suppose, in the common way of planting corn, might have yielded 35 or 40 bushels per acre; the other half inclosed was good hemp land, a small part of it being, in fact, too strong even for hemp. Early in September, I commenced feeding 110 hogs within the inclosure, and continued to do so until they were fatted, which was about the 10th of November. In March following, I carted from the stable green stable manure enough to cover, with a light coat, the whole of that part of the ground which had been exhausted by former cultivation; being careful to have none put on the other and better half. As soon as the frost was out of the ground, which did not occur till after the 1ts of April. I ploughed it well, harrowed and cross-ploughed it, in this way pulverizing the soil thoroughly. On the 14th of April, with a shovel plough, I laid it off into rows each way, two feet apart, and planted it, dropping two grains to the hill; I covered with a harrow, and followed the harrow with the roller. The whole after-cultivation was done with a hoe, which was tedious and required an amount of labor I had not anticipated on account of the growth of grass, timothy, and clover, and of many weeds. I gave it two hoeings, and, to have done it justice, it should have had the third. The crop was greatly injured and reduced by the occurrence of two storms of wind which swept nearly the whole to the ground, and besides many ears were entirely ruined by *blight*, the consequence of *bruises* received in *hoeing*. On the 7th day of September, I had the crop cut and put into stacks. I cut it thus early because being mostly on the ground and many rains occurring, the crop was injuring very much. My hands are today engaged in shucking it, and I will be gratified to have you measure it tomorrow.

Very respectfully, &c.,

GEO. W. WILLIAMS.

Messrs. E. CLARK & W. W. FORMAN.

[CERTIFICATE.]

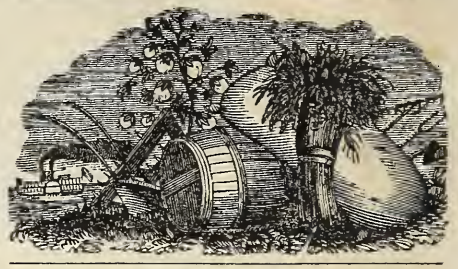
We, the subscribers, appointed by the Bourbon County Agricultural Society, to measure one acre of corn cultivated by George W. Williams, do certify that we have measured the same accurately, and there is 127 bushels, 6 gallons, 1 quart, 1 pint, and half pint, to the acre.—We were exact in the measurement of the land as well as the corn. Given under our hands this 28th of September, 1843.

EDWIN CLARK,
W. W. FORMAN.

Planters of Georgia! you especially who already "*know enough about farming*," we commend to your particular attention the facts contained in the above article. How many of you raise, as the average product of your farms per acre, one-tenth of this yield? How many of you cultivate an acre of corn upon your poor exhausted lands with less labor than Mr. Williams bestowed in the culture of this? And yet you raise fifteen to twenty bushels, while he raised one hundred and twenty-seven! nearly equal to the average production in Georgia of ten acres of land! This is no imaginary picture: every observant man knows that the average corn crop in Georgia does not equal two barrels per acre! Why is this? It is because there has been no spirit abroad in the land for improvement—it is because almost every planter in the land is foolishly striving to see how *many* acres of land he can cultivate, while little attention is paid to the system of culture or to the improvement of the soil. It is no argument against this large yield of corn that it was only accomplished upon a single acre; experiments should always be made in a small way—and an experiment on one acre serves as well to show what may be accomplished by an enlightened system of culture, as an experiment on one hundred acres—and in the event of a failure the consequences are only one-hundredth part as disastrous.

But we have another object in view, in calling attention to this article, and it is to ask—Do not these facts force the mind of every intelligent, reflecting planter, to acknowledge the important benefits to be derived from Agricultural Societies? We think so. Why not, then, form them in every county and neighborhood? Shall we grope on in poverty, ignorant of the improvements of the age, while all the world are enriching their estates, filling their purses, elevating and refining their intellects, and improving their lands, by the aid of Agricultural Societies and Clubs?

These are grave and important questions, and they deserve the grave consideration of those to whom they are propounded. Let the planters of the entire South contemplate the consequences to those who come after them, if they persist in that system of culture which has already quite exhausted one of the most fertile regions on the continent of America—let them survey in their mind's eye the squalid poverty which will be entailed on those who will be forced, from necessity, to dwell upon and cultivate] these worn-out and exhausted lands, and then let them contrast all this with the other side of the picture, a view which must be presented of the whole face of the country looking like a well cultivated garden; a bounteous plenty rewarding the labors of the husbandman, and domestic peace and quiet reigning supreme throughout the land,—all, all the results of an enlightened system of Agriculture, the immediate consequence of having in every county and neighborhood, Agricultural Societies and Clubs.



WEDNESDAY, JANUARY 10, 1844.

THE BACK VOLUME.

All new subscribers who may desire it, can obtain the first volume, neatly bound in boards, at one dollar the volume.

SEND IN YOUR LISTS.

As it is very important in regulating our edition to know what number of subscribers will probably be obtained, we beg our friends to send in their lists at the earliest possible day.

SEND US MORE SUBSCRIBERS.

However unwilling we are to trespass upon the indulgence of our readers, and to occupy our columns with matters pertaining to our own affairs, nevertheless we deem this a fit occasion, being the first number of our second volume, to add a few words to what we have previously said, to induce a zealous effort on the part of the friends of the "SOUTHERN CULTIVATOR" to extend its circulation. Of the interest which many warm friends have taken in its behalf, we have already had many flattering evidences in the shape of a long list of patrons, and to all such we should be wanting in justice to our own feelings, not to extend our most sincere and grateful acknowledgments. There, too, are others who have promised a zealous co-operation, from whom we have not yet heard, but we doubt not they are faithfully discharging their duty to themselves and their country, in their efforts to aid the extension of the circulation of an agricultural journal. We made an earnest appeal to the patrons of the first volume to go among their neighbors and friends, and invite their co-operation in furthering of our views. Many have already responded—most nobly responded—to this appeal, and we beg leave to renew it, and to include, also, those who have been recently enrolled on our list of friends for the second volume. Every man has his influence in society, and each subscriber to the "Southern Cultivator" may readily obtain one other, and many of them can obtain a hundred.

The necessity of some exertion on the part of our friends, now that our enterprise is in its infancy, is very apparent to every reflecting mind. In the first place, we are unable to publish the work unaided by the friends of agriculture, and as we have before remarked, we are quite confident that no friend of the cause de-

sires that we should go unrewarded for our efforts to promote the interests of the agriculturists of the Southern States. Again, the price of subscription is so low as to preclude the possibility of sending out traveling agents, even though they could travel among our agricultural friends free of expense. We can only hope, therefore, to obtain a general circulation for our paper, by the united and zealous efforts of the friends of the work, in their respective counties and neighborhoods. If this reasonable hope be disappointed, we have no other alternative but to abandon the enterprise; but we feel assured it will not be disappointed, and we will not, therefore, acknowledge any such word as *"fail"* in our vocabulary. Let but the friends of agriculture, and the agriculturists themselves, come up boldly to the work, and the day is not far distant when the Southern Cultivator will become to the South, what those of longer standing at the East and North have been and still are to New England and the Middle States. This is indeed promising much, yet it shall be fulfilled to the letter, if our friends, who have assured us of their aid as contributors, do not disappoint our just and reasonable expectations.

In conclusion, we beg leave to remark, that although our list is increasing daily, the number of subscribers is yet inadequate, wholly inadequate to remunerate us for our labor and expenses. In view, however, of a greatly increased patronage, we have worked off a large edition of this number of the paper, and all new subscribers may therefore certainly rely on being supplied with the present number, and the edition will be increased if circumstances require.

TO CORRESPONDENTS.

"Agricola," whom we welcome most cordially to our columns, asks, why it is that he has seen nothing in our first volume on the culture of Sea Island cotton. The answer is, doubtless, as he supposes, the Cultivator has very few patrons on the seaboard, and those few have not contributed a word on the subject, and as we were wholly ignorant of the system of culture of long staple cotton, our columns have, heretofore, contained nothing in relation to it. We however thank "Agricola" for inviting the discussion, and trust that it may elicit valuable information to the cultivators of that class of cotton.

With regard to the peculiar kind of land to which "Agricola" alludes, we suggest the propriety of first analysing the soil to ascertain its constituent parts, then by a comparison with the soil which produces the long staple cotton successfully, the defects may be readily discovered, and the corrective applied accordingly.

In reply to the inquiry contained in his postscript, we remark, that the cultivator is manufactured, in this city, by Mr. Alexander Philip, and is made stationary, or to expand to any desired width—price seven dollars.

A correspondent from Butts county, for whose frank and candid letter we thank him, takes us to task for the scantiness of our editorial remarks, and says we sometimes permit communications, containing incorrect views, to pass unnoticed.

"For instance," says he, "in the able report of the committee on cotton from the Newberry Agricultural Society, published in the Southern Cultivator, of the 25th of October, the committee say, 'the seed should then be strewed very *thick*, from three to four bushels per acre.'—Now I differ entirely from that report, in planting cotton seed thick, (unless the ground is very rough.) Cotton seed should be planted as thin as possible, to insure a stand. It would be best to have only enough stalks for a stand, and none to chop out. But as that connot be done, the nearer we approach to it the better. When cotton is planted thin, the growth is not checked, and it continues to grow. When planted thick, in sprouting, it bursts up the crust of dirt that covers it, leaves the roots exposed, and sometimes dies. If it does not die, when the hoe passes through, in chopping out, the stalks intended to be left, fall to the ground. But if there are but two or three stalks in a place, the growth is more vigorous, and the chopping out much more rapid and easy. After cotton forms the third leaf, it should be brought to a final stand as soon as possible, as it then branches better and matures earlier. As facts are worth more than arguments in planting, suggest to the chairman of that committee, Mr. Editor, to try a few rows of cotton planted thin.

"Again, in a communication from that minute observer and practical farmer, Mr. John Farrar, he comes to the conclusion, that this climate is too dry, to make as much corn per acre, as is made in more northern climates. I think Mr. F. is mistaken on that subject—at least, I hope so. On uplands, by proper manuring, and, perhaps, subsoiling, (I never used a subsoil plow,) or on rich bottom land, one hundred bushels of corn can be raised on one acre of land, and perhaps more, in the State of Georgia. The reason that I have come to this conclusion is, I raised the present year, on about seven acres of bottom land, on the Oakmulgee river, more than one hundred barrels of corn. Sickness prevented my measuring the produce of a single acre, which, if done, would have shown a large yield. The corn was planted on the 9th of May, and plowed and hoed only once. And from the seven acres thirteen large wagon loads and fourteen ox cart loads of close, slip shucked corn was gathered, besides pumpkins without number.

"I regret very much that an acre was not measured. Therefore vague calculations of the ground and quantity raised, prove nothing. It has convinced me, however, that one hundred bushels of corn per acre can be raised in this State.

"I am anxious that your Cultivator should be established on a firm and permanent footing.—The information diffused by it among the planters, will be worth more to them than all the rant about politics in all the pelitical papers in the State."

We plead guilty to the charge made against our editorial labors, and offer, in extenuation, that our arduous duties in another department of our vocation, prevented our bestowing as much attention on the Cultivator as we desired. This, however, will not be the case in future, as our arrangements are so made as to permit us to bestow more attention upon the editorial columns of the Cultivator than we have heretofore done. Another reason for not controverting the views of our contributors, was a desire, on our part, to invite discussion from others, whose practical experience would be of more value to our readers than our crude notions.—And we are gratified that in this we have succeeded so far as to draw out our correspondent, who, we hope, now that he has *"broke the ice,"* will continue to favor us with his views upon any and all subjects connected with the objects of our journal.

AGRICULTURAL PAPERS—PREPARATION OF COTTON.

In thanking our friend, Col. M'Donald, for his zealous efforts in our behalf, and the expression of his kind feelings, we beg leave to invite the attention of the reader to the subjoined extract from his letter. We concur fully with him as to the value of Agricultural Papers upon the productive industry of the country, and can but hope that the day is not far distant when their value will be more generally appreciated.

The preparation of cotton for market is a subject, astonishing as it may be in a cotton growing region, which we think is not sufficiently appreciated among our planters generally—though there are many exceptions. The truth is that too many of our planters are quite too careless in gathering and ginning it, and then by a very unwise system of economy they seem to think if they put it in bagging that will get it to the market in which it is first sold, it is all sufficient. Indeed it never seems to have occurred to this class of planters that, all cotton is bought by dealers with direct reference to the order in which it is when sold, and make their bids accordingly. As we shall devote considerable attention to this subject at the proper period for introducing it to the attention of our readers, we need not on this occasion say more than to assure every planter that, the proper care and attention to it, is always liberally rewarded by the additional price they receive for their cotton.

Eufaula, Ala., January 2, 1844.

"I should be extremely sorry to know that your work, the only one at this time in the region of the country, properly speaking, the cotton growing section, should not only be not sustained, but well supported. It only requires some exertion on the part of the farmers not only to sustain such a work, but to make it a useful and valuable part of every man's library. Next to the bible, each farmer should read and study an agricultural work, where he could learn a thousand different maxims that would apply to his every day business. He would there find out how his brother farmers do many things that he never once thought of.

In our region of country, we have prepared, the past fall, much beautiful and fine cotton.—The cotton raised in Barbour county has been selling at Eufaula, (many of the farmers not having to haul it more than ten to fifteen miles,) for 8, 9, and as high as 10 cents, and some lots have gone over 10 cents. The high prices are, no doubt, owing to two causes: the one is, that our soil is peculiarly adapted to the raising of the great southern staple; the other is, the care and attention bestowed in the preparation for market. The proper preparation of cotton for market is a subject that is too much neglected by nine-tenths of the cultivators of that valuable staple.

I made some twenty crops of cotton in a small way in my native State, Georgia, and I had been so often told in your city, and in Macon, by the purchasers, that my cotton was badly handled, that my gin was a bad one, that I determined, if possible, to prepare my cotton in a different way; that is, to make less and put it up so that when it came to be sampled, I would at least not be ashamed to stand by and see it drawn out. In a future letter I will probably give you my present system of preparing my cotton for market."

A NEW VARIETY OF CORN.

The following variety of corn, it is stated in a paragraph in the Cabinet, was brought from the Oregon Territory:

From the Farmer's Cabinet.

CALICO CORN.—The readers of the Cabinet may be pleased in hearing of an article of grain, that approaches nearer than any other in making flour and bread similar to wheat. I send a sample of the flour and two common sized ears of the corn. The hull or covering of the grain is of so many and various colors, that when ground fine, some of the particles being bolted through with the flour, may have a tendency to darken it some; but as to the color of the flour or bread, few, if any, could discover from the appearance of either, which was made from the corn, or which from the wheat, when laid by the side of each other. The bread of the corn, when mixed and prepared for baking in the same manner as wheat flour, will become light sooner than wheat; and in mixing, is more difficult; and for pies, does not stick together as well as wheat flour. In taste, a difference can be discovered. But let a person who has no knowledge of the article make use of the bread, pudding or pies, which occurred at my own table, and let him be asked of what the article was made, and he would pronounce it wheat—so near does it approach to it.

I have said enough by way of recommendation, as it will recommend itself more rapidly than seed can be procured. The object of my present remarks is more particularly to those who may become possessed of a portion of it to plant, that they may be careful to prevent it from becoming adulterated by mixing. It is not sufficient to plant a portion in the garden, and having a corn-field of other corn near by. It will mix much further than I could have believed, had I not seen it.

In raising what little I have, I planted it the 24th day of the sixth month, and gathered it the 10th inst., and my neighbor having a lot of corn near by, I purchased the privilege of topping, or cutting off the tassel, to prevent mixture. I am told, and believe, as much per acre can be raised, as of other corn; the stalks frequenly have two ears on, and the ears generally have as much on as other corn. I have observed almost every color among the grains of this corn, but I have not seen yellow, without believing it was a mixture. I have seen some lots that retained all the colors, but I had no doubt of their being much adulterated, from the hardness and shape of the grain—of their compactness on the cob, and their straight rows, which do not often occur in the genuine Calico Corn.

Please retain the two ears of corn and flour at the office of the Cabinet for inspection.

I have omitted to mention, that it ought to be gathered as soon as it is ripe, or it will swell, sprout and damage; particularly if the weather should be wet or damp. I had one and three-quarter bushels of shelled corn, weighing 72 or 73 pounds when taken to the mill, and had 30 pounds of superfine, and 20 of common flour—and 21 pounds of bran; and several millers agree in opinion, that much improvement in grinding might be made, with a little preparation. Respectfully,

A. W. TOWNSEND.

New Brighton, Pa., Oct. 30, 1843.

From the American Agriculturist.

LOTION FOR A BRUISE OR SPRAIN.

In a letter from Mrs. Susette Andrieu, a woman who, by instinct, experience and talent, is, as I am persuaded, the best nurse in these United States, I find the following recipe for sprains and bruises. My system has always been to spread such things far and wide, for the benefit of humanity and the brute creation. In every family there should be a common-place book, in which such things should be entered or pasted, for although we often hear of cures for burns, scalds, sprains, colics, &c., when these occur, we have either forgotten the materials or the proportions, or we have them not at hand. How many farmers are there who have such a thing as a set of phlemes to bleed a horse, or a bottle with the neck of it wrapped with twine, ready to administer a drench? But to the prescription for a bruise or sprain: 1 pint soft soap, 1 pint strong vinegar, 1 handful of table-salt, a table spoonful of saltpetre. I. S. S.

No man ever regretted that he kept aloof from idle companions in his youth.

The value of property destroyed by fire in the city of Boston, during the year 1843, was only $140,000.

AUGUSTA MARKET.

WEDNESDAY, P. M., January 10.

Cotton—At the close of last, and the early part of this week, our market was very quiet, and prices rather drooped. The news of an advance of ¼ to ⅜ of a cent in New York, with an active market, and very heavy sales, was communicated to only two of our heavy operators by a private letter on Sunday night, and as the Northern mail failed on Monday evening, they had two days to operate in on a flat market, during which they operated largely. On Tuesday night, however, the mail came through, and had the effect of producing a decided advance in our market, and to-day a much better feeling and more activity were manifested. The sales for the last three days have been to a considerable extent, at prices ranging from 7¾ to 9 cents—principal sales 8¼ to 8¾ cents.

Exchange– Checks on New York, Charleston and Savannah, are abundant at par. Central Bank bills are at a discount of 2 to 4 per cent. Georgia 6 per cents have not been so firm for the last few days, owing principally to the disappointment holders had been subjected to, in not receiving their interest in this city. This is, however, only a temporary depression, and the slight deduction which has been submitted to in the few sales that have taken place, will be instantly regained when the Governor completes an arrangement for paying the interest in this city.

GARDEN AND FIELD SEED.

A GENERAL assortment of fresh and genuine GARDEN and FIELD SEED, among which are the following:

Red and White Clover,
Blue and Green Grass,
Rye and Orchard do.,
Timothy and Herds do.,
Millet and Lucerne do.,
Seed Corn of every valuable variety,
Seed Wheat,
Buckwheat and Potato Oats,

Kept constantly on hand by the subscriber, all of which are offered for sale at very moderate prices. All orders, by mail or otherwise, executed with neatness and despatch.

SOUTHERN CULTIVATOR.

VOL. II. AUGUSTA, GA., JANUARY 24, 1844. No. 2.

ADDRESS

Delivered before the Hancock Planters' Club, by ELI H. BAXTER, ESQ., *Nov.* 3, 1843.

Let not the friends of good order be startled at declaration that I am, in feeling and principle, an agrarian! Not of that class of agrarians who contributed so much to bring about the decline and ultimate fall of the Roman Empire; not of that class who have been so prominent in warring upon the institutions of society, who, in their fierce zeal to level, would place the torch to the rich man's dwelling, and distribute among the idle and dissolute, the hard earnings of industry and economy—no; I mean an agrarian as its derivation imports—one devoted to the improvement and cultivation of the soil; one who is desirous of elevating, in the estimation of man, agriculture as one of the most honorable and useful pursuits.

To the most careless observer the necessity has become imperative, the conclusion irresistible—we must revolutionize our system of agriculture, we must improve our lands, or we must abandon our homes.

A tract of country upon which Providence has bestowed, with a profuse hand, his choicest blessings, has, by a most destructive system of culture, almost become, in appearance, a barren waste. At every point the eye meets the evacuated and dilapidated mansion—worn out and exhausted plantations. Fields that once teemed with luxuriant crops, rewarding abundantly the labors of their proprietors, are disfigured with gaping hill-sides, chequered with gullies, coated with the broom straw and pine, the sure indices of barrenness and exhaustion—all exhibiting a dreary desolation. Heretofore we have contemplated the gradual and certain deterioration of our lands with a careless indifference. Cheap and apparently inexhaustable supplies of rich land lay upon our borders. So even as our plantations, from exhaustion, ceased to reward our labors, we sought relief by removing to the rich lands of the southwest. But the inducements to emigration have ceased; this door of relief is closed; the choice lands in desirable situations are all occupied; their prices have become high, and there is now no alternative, but in expatriation, or remain and be content with a lean and scanty subsistence, or improve our lands.

In considering the subject of agricultural improvement, with a view to offer something new for its encouragement and improvement, I find every point has been occupied by Buel, Ruffin, Garnett, and a multitude of others.—They who follow those distinguished benefactors of mankind, can only repeat and urge the adoption of measures that have been repeatedly recommended by them. This consideration must not discourage us; we must have the fortitude to recommend ten thousand things that fall stillborn from the lips; we must subject ourselves to the mortification of making suggestions that will be received by many as contemptible and puerile. If Columbus could have been discouraged from his great purpose by the sneers and ridicule of his cotemporaries, the American Continent would still have been a howling wilderness. If the Christian disciple and missionary had abandoned the sacred desk, and ceased to preach the doctrines of the cross, because genius and eloquence had long since exhausted the argument, in convincing and persuading man to flee from the wrath to come, the sun of righteousness would long since have set, and the civilized world would have been enveloped by the dark clouds of superstition and bigotry. A spirit of improvement is developing itself, and attachment for our homes is increasing. To increase and encourage this spirit, and strengthen that attachment, should be the object of every friend of agriculture. To give a successful impulse to this spirit of improvement, it is important, indispensibly necessary, that we should be impressed with the truth of the proposition, that we occupy the choicest portion of country lying between the St. Lawrince and the Sabine. So long as we consider that other sections of country possess more natural advantages than our own, so long we shall continue restless and dissatisfied. This feeling of dissatisfaction is incompatible with a spirit of improvement. Men will not bestow much time and attention in the improvement and preservation of lands that they expect soon to abandon. Anxiety to move is his predominant feeling, and during this feverish impatience, he makes no improvement. To clear up, exhaust and turn out, field after field, until the whole plantation becomes impoverished and unproductive, has been the general system of agriculture in Georgia. Convince a man that his lands are valuable and desirable, and he will immediately set about their improvement and preservation. To accomplish this, we must compare and contrast. Let us then compare and contrast the advantages of the middle part of Georgia, worn out and exhausted as it is, with other sections of the United States.

My opportunities of forming a correct opinion of the relative advantages of the different sections of our country, have not been limited. Hearing of the great fertility of the lands south and southwest, and of their extraordinary productions, I caught the spirit of the times, and became impatient to see and examine for myself, those sections of country most prominent in the public eye for their fertility and production. I have seen the fine table lands of Alabama, Mississippi and Florida; the rich grain lands of Western Georgia; the rich alluvials of the Mississippi and Red rivers, and the richest of all lands that lie within the cotton region, the lands in southwestern Georgia; yet, after considering all their advantages, I esteem the lands lying in the middle part of Georgia, between the strata of rotten limestone on the south, and the line separating the cotton growing part of the state from the grain, as possessing more advantages than any of them. Fertility, climate, health, water and markets, are the subjects to which the considerate and intelligent agriculturist directs his attention, in determining upon the relative advantages of countries. A hurried parallel of them will exhibit our great advantages.

Fertility is the only advantage the most favored portions of the cotton region possess over the middle part of Georgia, and this advantage is confined to exceedingly small portions or tracts of land. Take, for instance, all the rich lands of Decatur, Early, Baker and Lee, and consolidate them, and they would not make a district nine miles square. Nine-tenths of the residue of the lands in these counties are poor, and the others are not surpassing in fertility the good lands of Hancock. These very rich spots in the cotton region are but painted sepulchres, exhibiting an attractive exterior, but within full of corruption and putrefaction—these rich spots are full of disease and death. The white families that do not retreat to healthier points, are never without the badges of mourning.—Their children that survive infancy, are delicate, sickly, and ricketty from the cradle to the grave. In these rich lands, the congestive and bilious fevers are raging from June to November. Those who reside upon them, spend their summers and falls in languishing upon sick beds, and when well, in watching by the bedsides of their sick and dieing families and friends. The industrious inhabitants of these rich lands can have an abundance of the good things of life, but they have no taste or appetite for their enjoyment—to the sick, the choicest delicacies are the most loathsome. What is life without health?—a miserable existence. Who can calculate the cost of so much sickness, anxiety, midnight watchings, and mental agonies for the loss of departed relatives. Is there not enough of sorrow and trouble in these low grounds, without increasing them by going to breathe the putrid atmosphere of those grave yards? How many of our acquaintances, who have settled upon these lands, have survived their deadly miasmas? Good water, one of the greatest blessing to man, upon these rich lands is scarce; what is found, is warm and unpalatable. With us, fountains of pure water gush from every hill-side; a temperature pleasant at all seasons, comparatively exempt from the ravages of the autumnal diseases of the south, and the inflammatory afflictions of the more northern latitudes. We can take the noon day sun, and breathe the night air of autumn, without the fear of those fatal consequences attending such exposure in southern latitudes; and we have a soil which, if restored to its virgin fertility, would quite equal their productions in the great staple of the south. At no point of the cotton region does the cotton plant do better than upon the fresh or manured lands of this part of Georgia. In 1842, James P. Knowles, a planter in Hancock, gathered thirteen bags of cotton to the hand, and made a plenty of corn and other provisions. Can Red river, Florida or Southwestern Georgia, do better than this? The difference in the productions of the two locations is comparatively trifling. If the Mississippi planter can average his seven bags of cotton to the hand, we can average five. Deduct from this difference the loss which the southern Planter sustains in slave property as compared with us, and we have the highest nett profit.

From observation and experience it has been ascertained, that the profit here upon slave property, by natural increase, varies from five to ten per cent annually, whilst the southern planter loses that much by death and physician's bills. It may be asked, if the productions of the two sections of country are so near equal, how is it that we find such a difference in the value of estates. It is easily and satisfactorily explained. It is mainly to be attributed to inheritance, and the too partial beneficence of the federal government A large proportion of the estates we find south of us, have been carried from this State, and the States north of us.—Here the farmer has from six to twelve heirs; the planters of the southwest have but few heirs,

the diseases of the climate most generally reduce them to one or two. The federal government has greatly increased these fortunes by pre-emption rights and other annuities.

If the relative advantages of the two sections have been correctly delineated, what should be the difference in the products to make them equal. To an intelligent and philosophic mind, no production that the laboror could gather after making, should tempt him to exchange situations. Before we conclude to fix our homes upon these rich lands, we should think of the beautiful couplet of Pope—

"Man wants but little here below,
Nor wants that little long."

Human life, when not abbreviated by disease, is but a span; to afflict that short period with the sufferings, mental and corporeal, incident to a sickly climate, is at best but poor philosophy. Here we can have health, long life, and lands, worn out and exhausted as they are, enriching their proprietors who are industrious and economical. The most of you have read an address lately delivered by the great New England statesman, at an agricultural celebration in Western New York. The occasion, the place, and the time for preparation, prompted and enabled that distinguished man to throw into his address all the powers of his highly gifted mind. Bis great object in that address, seems to have been to exhibit the great advantages which Western New York possessed over the planting portions of the world. The repeated bursts of applause from his audience tell, in strong terms, how successful he was in accomplishing that object.

I have considered all his reasons and positions, and they but confirm me in the opinion, that our portion of the State possesses, in a much more eminent degree than Western New York, all the elements conducive to the wealth and happiness of man. His conclusions are correct, as applicable to countries exclusively adapted to planting and grain growing, but totally inapplicable to us. His contrasts and parallels, as he has carried them out, not only exhibit our advantage over plantation States, but over grain States. He says, that "he planter makes but one product for sale and buys twenty; that consequently, a failure in the crop, or a serious fall in the price, is attended with the most disastrous consequences. Having to buy every thing, if he fails in a crop he is ruined; if his product declines ten per cent in price, it affects to that extent his whole annual income. Western New York is independent of these vicissitudes, because she produces every variety of production, both vegetable and animal, necessary to the comfort of man. It is this variety which constitutes the great advantage of the farmer of Western New York. If his crops fail, and prices fall, still he is independent; his family is fed and clothed out of his own productions."

Every one who hears me, knows that we possess, in a much more eminent degree than the farmer of New York, all the elements of independence. What, grain, vegetable, or animal, that they can raise in Western New York, that we cannot raise here? If their tables are supplied from the products of their own soil, so are ours; if their families are clothed with fabrics made from their own fleeces, so are ours. If we cannot raise as much wheat and corn per acre as the farmer of New York, we can raise an abundance for our own consumption, and make heavy crops of cotton, that control and regulate the trade and commerce of the world. If they have health and good water, so have we. The mildness of our climate makes our productions quite equivalent to theirs in sustaining animal life. In New York, their first fruits ripen in June; here we have a great variety of fruits ripening from April to November. The orange and pine apple, the only fruits of the tropics that are desirable, are brought to our doors, at such prices as the poorest farmer can buy them. Notwithstanding we export large quantities of the great southern staple; notwithstanding we direct all our energies to its production, reserving our best lands for it, yet corn and wheat are as cheap here as they are in New York. If our old worn out soils can do so much under our wretched system of culture, what could they not do under the improved system of the north? If we can make so much grain, and yet make so much cotton, what could we not do if all our labor was directed to the making of grain? Here we can be farmers or planters, as taste or interest may dictate. Indeed, our lot has been cast in pleasant places. We can have the independence of the farmer, and enjoy the superfluities and luxuries of the planter of the tropics.

The same distinguished gentleman, to please his audience, drew a parallel between the condition of society in the planting and farming communities. He inquires, "What is society in the plantation? There is no society. There is a capitalist, and there is a labor of a particular description. But as a society, a society of intelligent and free spirits, there is none, none, none, and there never can be." 'Tis true; the parallel is drawn between the West Indian planter and Western New York. But we are planters, and we have labor of a particular description—yea, we have slave labor—yet our society is free, intelligent, and virtuous. Our latitude and temperature is particularly favorable to the development of the highest grade of physical and intellectual powers. The institution of slavery has *not* impaired the spirit of liberty. Upon this subject the views of the celebrated British statesman are beautiful, and true as beautiful—"Where there is slavery, those who are free are by far the most proud and jealous of their freedom. Freedom is to them, not *only* an enjoyment, but a kind of rank and privilege. Not seeing there, that freedom as in countries where it is a common blessing, and as broad and *general* as the air, may be united with much abject toil, with great misery, with all the exterior of servility; liberty looks among them like something that is more noble and liberal. Here the people of the Southern States are much more strongly, and with a higher and more stuborn spirit, attached to liberty than those of the North. One of the great obstacles to agricultural improvement, is the low estimate put upon it as a pursuit by all classes of society. The cultivation of the soil is considered a pursuit unworthy of the attention of the scholar and gentleman. The successful planter educates his more gifted sons for one of the learned professions, whilst he destines his less intellectual for the farm."

It has become common for the agricultural class to look up to the merchant and the learned professions as a higher order of society. The young man of genius and ambition, looks upon the cultivation of the soil as a grave that is to keep in perpetual night all his high hopes of distinction. This feeling in society is radically wrong, and has been mainly superinduced by the humble and unpretending character of those engaged in it. The capacity of the intelligent planter to serve the country is overlooked, and his claims for office superseded by the babling politician of the village and city. To engage in agriculture is a voluntary ostracism. This subject has attracted the attention of every one who has taken any interest in the cause of agricultural improvement. It is a subject of regret and lamentation in every agricultural address; yet it is a prejudice so deeply rooted in society, that no remedy has as yet been suggested that promises to eradicate it. The intelligence of the people has been appealed to; agriculture has been exhibited with all the attractions that genius and fancy could throw around it; education of the agricultural classes has been recommended and adopted without effect. Still the young men of genius, promise and education, all throw themselves into the learned professions; still the cultivators of the soil are content to be considered a menial class in society, subservient to the merchant, mechanic and professional man; having little or no participation in the offices of honor and profit which they confer. Before we can make much progress in the great work we have embarked in, public opinion upon this subject must be revolutionized; this disgraceful prejudice must be hooted from society. To effect that revolution, the remedy is easy, simple and effectual, and you have it in your own hands. The agricultural class constitutes six-eights of our population:—you must make your numbers and your influence tell at the ballot box. Agriculture sustains all the great interests of every country. She feeds the people, pays all the expenses of the government, in peace and war. She should not be content with casting her vote for those who are to rule over it, but she should have agents from her own body to participate in the administration of the government. Let her claim her ratio of representatives in the State and Federal legislature—it is her legitimate and constitutional right. Organize and unite, and you cannot fail to enforce this right. Teach the young aspirant after fame and distinction, to look to you for the gratification of his wishes; make agriculture the theatre upon which genius and talents are to exhibit for popular applause, and you will soon eradicate from the public mind that contemptible prejudice that has been so long operating so injuriously upon this great interest. The imposition of taxes is considered one of the most important duties of government, and hence it has become a fundamental principle in free governments, that those who pay the taxes should impose and regulate them. It was the disregard of this salutary principle by the mother country, that excited her colonies to revolution. The mischiefs to the public interest, growing out of a disregard of this principle, is too apparent in the legislation of many of the States. The debts of many of them have become so large as to startle the patriot and statesman. Some are so distressed with this debt, as to seek relief in the discreditable, disgraceful remedy of repudiation. If the farmer and planter had have had the control of the public councils, those ruinous and reckless projects that have created this indebtedness, never would have been adopted. It is only the cultivator of the soil that knows any thing of the toil necessary to make a dollar; and these are the men who, in our legislative assemblies, are for holding close the purse-strings of the State. If the journals of the legislatures whose actions have been characterized by such wasteful expenditure of the public money, and abuse of public credit, could be examined, I feel assured it would be found that they are controlled by men belonging to that class known in political economy as the unproductive.

Though all admit the great importance of this branch of the public interest, yet look to your own legislature and see how it is neglected and disregarded. You will find upon its journals, a long catalogue of standing committees upon various subjects connected with the public interest, yet you will find no standing committees upon agriculture. Long and elaborate reports are made upon the contemptible humbugs of the day, yet not a breath is spent upon this all important interest. In eighteen hundred and ....., a time of unprecedented gloom and distress to the planters of this State, the legislature passed a law offering an encouraging stimulant to the cultnre of silk. At that juncture it was a political measure that would have been creditable to such geniuses as Pitt and Clinton. The great staple of the State, from a concurrence of causes, was so depressed as not to pay the cost of production; and there was no prospect of improvement, as the low prices proceeded from over production. The country being deeply in debt, distress was predicted by every tongue, and time has verified the truth of their anticipations. Expecting no relief from the culture of cotton, the people began to direct their attention to the culture of silk. Many made considerable investments; all believed it would be profitable; yet no adequate and persevering effort was made. At this juncture, the legislature passed a law offering a high premi-

um upon silk culture. Many embarked into the business, stimulated by the public bounty. At the next session of the legislature, the law was repealed, and all that had embarked in it, in discouragement, abandoned it. Why the friends of agriculture did not sustain this measure, is a circumstance that has always excited my surprise; it is a fact, however, that forcibly illustrates the necessity of this great interest being more efficiently represented in the halls of legislation. If the silk culture can be made profitable in this State, what a loss has its citizens sustained by a discontinuance of the bounty.

Two years more would have attested the question. If unsuccessful, the bounty would have cost the State but little; if successful, the people could have paid millions. The exhausted hill-side, and the pine barren, would have been covered with the mulberry, and we might have been realizing from its culture as much as our fathers did from the culture of the cotton plant.

As a measure of advancing this branch of industry, the encouragement of agricultural societies, fairs, the distribution of premiums, and patronage of agricultural papers, cannot be too strongly recommended. Every citizen who feels an interest for the welfare of society, without regard to his pursuit, should enroll his name as a member of some agricultural society. If a mechanic, you have an interest in the great work. If the farmer makes good crops, you will get more work, better paid, and provisions cheaper. The same argument applies to the merchant. We want the influence of your names, and presence, and purses. These annual celebrations are fit occasions to beat up for volunteers in this great work, and we most respectfully invite one and all to come and go along with us in this great work of benevolence and humanity. It is in truth a work of humanity and benevolence! It will not only increase our means of clothing and feeding the poor, but agriculture makes employment abundant and profitable, and where there is plenty of employment, there are no poor. The benefits of these fairs must be apparent to all. Who can look upon these fine exhibitions of stock without resolving to make an effort to improve his swine, cattle or horses? Who can look upon the improved implements of husbandry without its suggesting to his mind something that may be turned out to profit. Recollect, that one of the great improvements to the cotton gin, the brush wheel, without which it never could have been instrumental in bringing about that revolution in commerce which has so distinguished the seventeenth and eighteenth centuries, was suggested to the mind of a lady, by the exhibition of the model by its immortal inventor.—They not only create a spirit of emulation between farmers, but between ladies. The splendid exhibitions of the domestic fabrics that surround us, show that the ladies are taking an interest in this great work; they give us their presence and smiles, and when woman smiles, success universally crowns the efforts of man, no matter how perilous the enterprize. Perhaps, too, they may be instrumental in substituting the old fashioned and too much neglected music of the spinning wheel, for the contemptible and too common thumbing upon the piano forte. I consider, however, the distribution of premiums as decidedly the most efficient in giving effect to agricultural improvement. It is now no experiment; its efficacy has been amply attested in Europe and this country. Scotland has quintupled her products. In every country, climate and soil, the agricultural products have been increased to an incredible extent, where this artificial stimulant has been applied. Here we want legislative aid, and you will be recreant to this great interest if you do not get it. We not only want premiums for the best stock, the best implement, and the best domestic fabrics, but we want premiums, and high premiums too, for the best ditched plantation, the best crop of wheat, corn and cotton. It is upon the improvement of our lands we wish to see all the intelligence of the agricultural class directed. There is no want of knowledge in the cultivation of our soil with our farmers; but they are ignorant as to the best means of making and applying manures. It is here we want the light of science. She has snatched the thunderbolt of Heaven and placed it powerless at our feet; she has made safe highways through the "pathless ocean;" she has annihilated time and distance; she can and will, in due time, make discoveries as wonderful and beneficent for this great interest; she has already discovered, in many places in the bosom of the earth, inexhaustible supplies of manures; she is still at work, and perhaps it is already accomplished by the discoveries of Jauffret. By this discovery we can convert all vegatable matter, in a short period of time, into rich manure. If his process succeeds, these old plantations of ours will soon teem with crops as luxurient as when in their original fertility. We want gullies filled up and leveled, and plantations made rich; we want high premiums to stimulate farmers to make efforts commensurate with these great objects. Societies are too poor—the State must do it.

"One of the most remarkable features of modern times is, the combination of large numbers of individuals, representing the whole intelligence of nations, for the express purpose of advancing science, by their united efforts of learning its progress and of communicating new discoveries." It is to this circumstance that we must attribute the accelerated progress men make in modern times in the arts and sciences. We want legislative assistance to accelerate our improvement in this great interest. $25,000 to be given by the State annually in the way of premiums, would be attended with the most beneficial effects. What substantial objection can be urged to a mere regulated system of premiums furnished by the State? For the State to patronize one branch of industry at the expense of another, is unjust, and ought not to be tolerated; but this reason does not apply to the encouragement of agriculture. All classes and pursuits participate equally in benefits conferred upon it. "Speed the plow," and you will give a corresponding animation to the business of the mechanic, merchant and manufacturer.

A distinguished ethical writer of modern times, has well remarked, that the final view of all rational politics, is to produce the greatest quantity of happiness in a given tract of country. The richest thought and glory of nations, the topics which history celebrates, and which alone almost engage the praises and possess the admiration of mankind, have no value farther than as they contribute to this end. When they interfere with it, they are evils, and not the less real for the splendor that surrounds them. The happiness of a people is made up of the happiness of single persons; and the quantity of happiness can only be augmented by increasing the number of the recipients.

That it may and ought to be assumed in all political deliberations, that a larger portion of happiness is enjoyed among ten persons possessing the means of healthy subsistence, than can be produced by five persons under any advantage of power, affluence and luxury; that consequently the decay of population is the greatest evil that a State can suffer, and the improvement of it the object which ought, in all countries, to be aimed at in preference to every other political purpose whatsoever. Here the duty of the politician is clearly and distinctly laid down—increase population in order to augment human happiness. The population of every country depends upon its productions.—The district of country that produces fifty bushels of corn to the acre, will sustain five times the number of inhabitants that a district will that produces but ten. Multiply, subtract and divide, and see what a difference in the sum of human happiness is to be carried to the credit of that government which, by a system of policy, quintuples her productions and her population.

To be continued.

Great Yield of Wheat.—Mr. T. C. Peters, in a letter to the "New Genesee Farmer," says:—

The largest yield of wheat that I have heard of this year, was in Alexander, Genesee county, N. Y. Mr. James Lewis, of that town, raised from 2 acres and 70 rods of ground, 140 bushels, clean for seed, and 8½ bushels shrunk wheat; 60 pounds to the bushel. This is a trifle over 60 bushels and 2 pecks to the acre. The wheat was thrashed and accurately measured. That there might be no mistake, I requested a friend to procure from Mr. Lewis a statement of the whole of his crop, method of cultivation, &c. I will remark, that I am personally acquainted with him, and that he is a man of strict integrity and veracity.

The whole field in wheat was 17 acres and 71 rods; principally bottom lands on the Tonawanda Creek, and of course alluvial soil. The previous crop was corn and spring wheat; no manure applied to present or previous crops.

"The ground was "summer fallowed," plowed twice in the season, and dragged three times. It was sown from the 5th to the 10th of September, broadcast, one bushel and a half to the acre. The seed was the "Red Chaff Yellow Flint." It was harvested from the 1st to 6th of August, 1843. The wheat was thrashed, and accurately measured. The whole product was 677 bushels clean for seed, and 70½ bushels shrunk; equal to 42¾ bushels per acre.

The above 2 acres and 70 rods were taken in a body, from a portion of the field.

Here we see, that if the soil be in a proper condition, it will produce 60 bushels of wheat; because it has been done in our midst. There is no mystery about it.

Valuable Cows.—At the meeting of the Agricultural Society of New Castle County, Delaware, in September last, Mr. Holcomb exhibited 8 beautiful native Devons, among them the celebrated Cow "The Lady." The result of twelve weeks' trial with this cow, gave 174 pounds 12 ounces of butter, averaging 14 lbs. 9 oz. per week—the highest product in any one week being 19 lbs., and the lowest 12½ pounds. To Mr. Holcomb for this Cow, the committee unanimously awarded the first premium.

Her feed the first part of the time was hay, and dry oat and corn meal mixed—subsequently this was changed to slop: two buckets a day was regularly given her, containing about two quarts of corn meal, and as much wheat bran, mixed in a bucket of warm or tepid water, with a little salt. The week of her great trial, in June, she was fed for about ten days on three gallons of meal a day, at three feeds, mixed as above. She had the run of a good pasture, and she was also, for a time, fed on green oats, and again with corn fodder that had been sown broadcast.

The Weeeling Times gives an account of a cow, the property of Dr. H. W. Chapline, of Ohio county, Va., which was milked three times a day, and yielded in the months of May and June, for 16 days, upwards of 34½ quarts of milk! and during two weeks that a record was kept of the amount of butter manufactured from the milk of the same cow, showed a yield of 29 pounds, an average of 14½ pounds a week.—These facts are substantiated, the Gazette says, by the affidavit of an individual whose word alone would gain credence for more extraordinary statements.

Who can beat it?—The Little Rock Gazette of the 27th ult., says that on the plantation of Mr. R. H. Douglass, in Arkansas county, one of his boys gathered 601 pounds of neat cotton, (white and clean as usual,) in one day—and that another boy belonging to the same gentleman picked 649 pounds, (not so clean, however,) in a day, making together 1250 lbs. On another day the same boys picked 1042 pounds.

From the A[illegible]y Cultivator.

THE IMPROVED [illegible]TURE OF COTTON.

Messrs. Gaylord & [illegible]ucker—Entertaining the profoundest respect and the kindest feelings towards the opinions and practices of those planters who are greatly my seniors in age and in agricultural experience, I propose now, in this third paper, to engage in discussing "the principles and philosophy of this improvement in the culture of Cotton." I will first remark, directly, gentlemen, what I have intimated thro'out this correspondence—that in conducting these experiments, and in advocating the claims of this improvement, (the leading and meritorious features of which belong to your invaluable Cultivator,) I have had no ambition to gratify, which is not common to the lover of science and agricultural improvement; nor have I any interests to subserve thereby, which may not be the privilege of every planter in the country, however humble his pretensions or ability. Yet, admonished as I have been, by the precipitate and unmeasured tirade of vituperation and spleen, which my first paper excited among the corps editorial of the country, and others of the "skinning gentry," I have not ventured upon this most delicate position, though long promised, without again revising carefully and practically, the principles and ability of this system.

In my first paper it will be recollected, I stated the grand object which this system of improved culture proposes to accomplish for the planting interest of the country, and I also gave there a fair and impartial, and a most satisfactory expose of that system, (if such it may be styled,) by which the cotton plant is at present grown. In my second number, I gave in detail, in an equally plain and simple manner, the *modus operandi* by which my experiments were conducted; this was no second hand report, or say-so of another person, but in part the work of my own hands, and the entire management under my immediate supervision. In this paper, I propose giving *the why and the wherefore* for all this—at least, in my humble opinion; and to point out the *inconsistent*, the *reckless* and *grassy* policy of the present practices of the country, as compared with the *systematic*, *economical* and *philosophic* policy of this improvement.

It is my purpose, gentlemen, first to give you a correct sketch of the botanic characteristics of the cotton plant, as we meet with it under the circumstance of its most favorable culture. I do not offer this in the spirit of ostentation, to appear learned from the technicals used, (the necessary peculiarity of every science.) My object is simply to call attention to a subject—too much neglected by planters—about which the books are carelessly in error; and a proper knowledge of which, in my opinion, tends greatly to indicate the best or right mode of culture.

The botanic name then, of the plant we cultivate, is *Gossypium herbaceum;* we find it in the fifteenth class of the Linnean system, (*Monadelphia,*) and in the thirteenth order, (*Polyandria*) The first leaves that make their appearance after the cotyledons, three to six are *ovate*, and indicate certainly the sucker or branch limbs, that will first put out from the stalk. After these, we have the cotton leaf proper, *three to five lobed*, and mercronate, with one gland upon the *mid-rib* beneath; these leaves invariably indicate the arm limb, growing out horizontally, and articulated, forming at each joint one or more balls; coming out with the arm limb, we have almost invariably a branch limb, with several balls—or a stem with one to three balls. The stalk is *ligno*-herbaceous and *pubescent*—and in our climate an annual, attaining the height of *six to ten feet*. The period of flowering is from 10th *June to frost;* the calix double, the outer one three-cleft; capsule 3 to 5 *celled*, with 7 to 9 *seeds* in a cell, involved in the staple. Early in the morning the *milk white** bloom may be seen, in the form of a conic scroll, emerging from the fringe work of its outer calix; and with the rising sun it unfolds the segments of its petal, and by one hour by sun we behold the full blown bell-formed flower. Thus, blooming white, it remains till 12 o'clock, when within 15 minutes thereafter, we may observe by the naked eye, a faint ray of pink skirting the thin margins of the segments, which pink color may be seen by one to two o'clock, to have diffused itself throughout the bloom. It thus continues changing from white to red, till sun up the next morning, when it will be found a beautiful brilliant pink; now with the rising sun it gradually wilts, and by 12 o'lock it drops off, leaving a distinctly formed ball, securely sheltered by its calix.

This description, which is strictly correct, differs in several of its particulars from Eaton's, and from the miserably erroneous engraving and description of the same, to be found at page 307 of "Sears' Wonders of the World;" and yet strange to say, this same engraving, with probably but a single correct feature, is copied into the "American Agriculturist," in illustration of an article by Dr. Philips. I might point out a half dozen errors in that engraving; it will answer my present purpose however, that I detain you with but two or three such notices. You will first observe the bloom and the description given, and you will agree with me at once, that Mr. Sears has been *bugged* by an okra flower; the cotton bloom in its healthy state, is never so much flared, nor has it any *red spots* in the bottom. Observe again to the left, that young ball with its *drooping calix;* that is altogether unnatural, and is never seen except where the worm is or has been. You will observe the same error in the opening ball; every little boy, who has picked but fifty pounds of cotton, will tell you if that were the fact, there would be no trashy cotton. I am sure Dr. Philips has detected these blunders, with others equally evipent. This I suppose will be sonsidered a small matter, about which nobody is at fault; because even intelligent planters have never thought it worth while to give a correct description of the cotton plant. This same carelessness is observed, when we cast our eyes upon the large map of Alabama; we there see a most imposing engraving of a large *fancy plant*, with its one hundred and one errors, if called a cotton plant. Observe again, the beautiful and chaste vignette of our own excellent and cherished "Southern Cultivator; we see there an engraving designed for the cotton plant, yet I am sure if the *pendent* open balls were painted *red*, you would sooner take it for a pomegrante bush!

To the planter who is satisfied merely to plod along the inanimate imitator of some skinning neighbor, this sketch will appear a tedious and uninteresting detail. I am convinced, however, of its importanee—and there is a spirit of improvement abroad in the land, which requires just such detail of fact; because it is not possible, at least it is extremely improbable, that we succeed in improving and perfecting the culture of any article of vegetation until we make ourselves *well* acquainted with its natural characteristics. Hence I remark, that when we look upon the stately pyramidal appearance of an improved cotton stalk, grown under favorable circumstances, we observe at once—indeed, we are forcibly struck with the distance proper in its arrangement upon the soil, which is so clearly indicated. Again, we observe an uncommonly large amount of foliage for an annual, besides some 3 to 4 lbs of seed cotton upon the stalk—literally crowded from its base, upon an area of some 15 to 20 square feet, to its apex, at the height of 6 feet. Now in view of these clearly established facts, the invariable effect of certain well defined causes, I shall not suppose any planter so dull as not to know what course to pursue, if he find that it require a given amount of grain to grow a pig to a given size in one year, that to produce another such pig the next season, the necessary amount of food or grain must be first supplied. Without the food, the pig will be found at the end of the year a *landpike*; and so the cotton, without the geine and manure, will be found, as is too common, the *little Frederick!* Were I to assume an affirmative position in this analogy, every planter would reply instanter, and most indignantly too—Sir, you are behind the times; our own sage Franklin, more than a half century ago, in his friendly advice to Poor Richard, has assured us, "that by constantly taking out of the meal tub and never putting in, we shall soon find the bottom." Philosophically true this—good homespun and sound doctrine; yet plain and simple as be this doctrine, the cotton planter knows it only in song—his acquaintance with this golden truth is theoretic entirely. His exhausted fields and dwarfish puny cotton, tell tales more positively contradictory and gloomy, than I have room or inclination here to enumerate.

The governing principle then, in this improvement, is to give constant and diligent attention to keep the *meal tub well supplied*. In the first place, produce and haul out upon your land a sufficiency of good manure, fully to supply the requirements of the plant all the season. In another place, I have shown that it is a perfectly easy matter to produce this manure, to which I will further add here, that the decaying materials abound spontaneously, scattered up and down, filling each nook and corner on every plantation, during all the season, a waisting nuisance that might be casily collected and converted into a profitable revenue, if but one-third the time and attention otherwise sedulously consumed in the butchery of the soil, in a petit war against grass and weeds, the inevitable produce of such latitudinarian systems of culture, was devoted to that most valuable employment. In this most important department of agriculture, science is actively engaged in rendering the planter the most essential service.

Having derived these important indications from the figure and natural characteristics of a perfectly matured cotton plant, the judgment of the planter is brought into active requisition in properly adjusting its relative position in width of row and its situation on the drill, in order that we secure the greatest possible advantage in its subsequent culture. My own experience inclines me to the opinion, that when land is improved only to the extent of 150 to 200 bushels of manure per acre, less than fifteen square superficial feet to each stalk will be too close. Nor will improvement carried to five times that extent, require greater distance than twenty square feet to each stalk. Since, then, it is found necessary that each stalk occupy this distance, it would appear that the simplest course would be to lay off the rows equi distant each way. The question is frequently asked, "Why not lay off the land 4 by 4 feet, or 5 by 4 feet?" There is a very serious objection to this simple plan, which every planter must perceive on a moment's reflection. In either case, the cotton will be found so entirely interlocked by the 20th June to the first of July, as to forbid further work; yet we find, under the most favorable circumstances of seasons and culture, that it will take the stalk until the 10th July to attain the height of six feet, short of which we should not top it, nor earlier in the season; and it is very desirable, and highly necessary even, that the cotton be swept once after topping it, which we find impracticable unless the rows be laid off wide one way, with a view to that desirable operation. Upon land then, that is but moderately improved, I prefer the rows north and south 5 feet, by 3 feet east and west; and upon land in a higher state of improvement, 6 feet by 40 inches will be found the best distance. Though we shall find the stalk a little crowded the narrow way by this course, yet we secure the more important advantage, in being able to scrape and pulverize the surface later in the season. I suppose there to be other advantages likewise, in this plan of laying the rows at right angles, north and south, and east and west, and bedding the land north and south, to which, however, I must refer at another time.

The next object to which I shall direct your attention, is the mode of culture which I conceive to be necessary in the after management

*The Sea Island Cotton bloom is yellow.

of the cotton plant; the correctness, and even superiority of which, I hope to establish as clearly here, as in practice it has so triumphantly succeeded. The constant and invariable success which attends this improvement in my hands, is the result of a *strict and scrupulous adherence to system in its management.* Every science and every profession among men, which is either useful or valuable, acquires both respect and importance on account of system. System is essential to certain success in every undertaking; and especially is it necessary in this first of all professions. The principal object I have had in view, in all this manuring, thorough plowing, laying off and bedding the land previous to planting the seed, has not been to plant alone; men plant abstractly, as handsomely and with the same facility, with less labor; it has been done to encourage and facilitate the early and extensive growth of the fibrous and soil roots, by which means the plant readily and equally early, augments the extent of surface (in number and length of its limbs,) for fruiting, and the consequent number of its organs of atmospheric nutrition. The immense advantages which the plant derives from an early accomplishment of an object so desirable, are at once obvious when we recollect "that the soil and atmosphere offer the same kind of nourishment to the roots and leaves of the plant."—There can be no reasonable doubt, though I possess not the means of positive measurement, but that the plant multiplies its organs of atmospheric nutrition in precisely the same ratio that an improved and judicious system of culture facilitates the growth and prosperity of its roots. There is also another interesting consideration connected with this subject, which I esteem worthy of notice in this place; which is, that though the soil and atmosphere offer the same kind of nourishment to the roots and leaves of the plant, yet the character of its assimilation and consequent appropriation widely differ. My own opinion is, that the roots assimilate food for the production of the stems and leaves mainly, and that the leaves assimilate the same for the production and maturity of the blooms and fruit. I do not claim originality for this opinion; I think I have seen it hinted at in some work on vegetable physiology, though I cannot now say where.* I have been governed by this impression, at least in conducting my experiments, which have not as yet been of a sufficiently varied character to enable me to determine and assert the fact positively. My attention was first called to this interesting subject while investigating the cause and effect of rust upon the cotton plant, which every planter has seen, some of the features of which would seem to strengthen this position. How desirable is it, then, if all this be fact, that we adopt such system in our after management as will not only preserve this natural chain of action unimpaired, but encourage its progressive prosperity? It is not enough, however, that we thus dismiss this part of the subject; its importance requires of us a much more simple and extended view.

We will commence then, at that age of the plant at which it is first worked, by examining the roots of two stalks: we pull up one in the ordinary way of thinning cotton, that is, we take hold of the stem and draw it up, and we have a single long root (in most instances) tapering to a point; we have simply the tap-root. We will take up the other with a spade or hoe, the stalk standing in the centre of some six to eight inches square of soil; we then gently sift or shake the soil from the roots, and we have a fair specimen of the cotton root: we have what is properly meant by tap-root, a plant with a main root long and tap-like or tapering, dipping deep into the soil; beside this tap root, however, we find an almost innumerable quantity of fibrous or surface roots diverging in every direction, as long in many instances as the tap root itself, and coming out generally from one-half to one inch below the surface. This is a fact worthy of notice, with which every planter may, if not already aware of it, acquaint himself early the next season. This may appear to some persons a very simple and a very trivial investigation, yet I find in it a most satisfactory solution of the immense injury which the cotton plant sustains from the multifarious policy of the country. I remark then, as the plant comes forward, so the tap root (where it exists, though an unnecessary appendage in our climate,) sinks deep into the soil, while the fibrous or surface roots multiply and shoot in every direction; hence I say, "as early as possibly convenient" after the plant is up, "plow out the middles *well*, the wide way, having first run around the plant with a scooter plow." The main object in this operation, is once more, before the surface roots have come out so far as to sustain injury, to thoroughly loosen the soil and again commingle it with the manure. The plant being now thinned down to two or three stalks in a place, and a small quantity of soil molded about the hill, is left in this most favorable and growing situation. In the course of some fifteen to twenty days, when we return to work it again, it will be found to have come forward rapidly, standing from 12 to 15 inches in height and finely limbed. If we now take the trouble to examine a hill or stalk, we shall find an amount of earth included within the circuit of these fibrous and soil roots, as they penetrate all parts of the loamy mold in pursuit of the luscious geine, (like a flock of sheep fresh upon a rich pasture,) that will weigh more than a hand can tote. With these facts before us, let us turn our attention for a moment to the practices of the country at this stage of operations. One planter will now commence work, and the plant standing from 10 to 12 inches high, "with a bull-tongue or scooter plow," and he will dagger into the soil, as close to the plant as he can possibly get, some 3 to 4 inches deep—he says, "to loose up the earth, that the tap-root may go down." Another planter will again, the second and third time, run the bar of a turn plow to the cotton—he says, "to kill the grass;" thus it stands bedded in the middles, and "steaming" a few days, when these hot beds are plowed out; though I have even seen it barred the third time before plowing out the middles! All this may answer the *purpose fully*, and even look very well to the planter that operates to kill grass; but we have a latent cause operating destructively in this practice, and though the *certain effect* is not always willingly recognized in the turning yellow and falling leaves of the plant, it is not however the less obvious. The planters operating thus, will tell you, in the first instance, "this cotton has received a fine working; there's not a sprig of grass or weeds to be seen; but it does not grow off as it should; this *little dry spell* has checked its growth." But partial showers may have fallen upon the other man's cotton; he says, "See my cotton; how clean and nice it is worked, though it is too wet and does not grow; *rainy weather* does not suit cotton." This is the logic (I will not say universal) of the devotees of this *grass killing* policy, in accounting for its disastrous consequences, and will, I am sure, be very readily recognized as such by every impartial man. Now, the truth is, I will illustrate the whole difficulty here, by a very simple, though rather uncouth simile; it is however not the less pertinent to my present purpose, because men are not to be benefitted, nor will they improve in the practice of any science or profession, unless they exercise the faculties of thinking and reasoning, though such exercise be bought at the expense of decent ridicule. We will suppose the planter operation in this was, having received a pair of fine Berkshire pigs, says to his trusty man, Sambo, "take this bushel of corn to the barn-yard and feed those pigs well; I want them to grow *large* and *fat*." Well, Sambo, always anxious to carry out the views of his master, and having carefully watched his operations in the treatment of his cotton, to make *it grow large*, takes up the basket, and then providing himself with a hammer or hatchet, he proceeds to the yard; he first takes hold upon the gentle, unsuspecting grunters, one by one, and with his instrument he knocks or breaks out their teeth, and then throwing down the corn, he returns to the house with spirits buoyant in the consciousness of having so consistently discharged his duty! "Well, Sambo, you have given those pigs plenty of corn, ha?" "Yes, sir, they are well fed." In a few days he takes a friend to look at the fine Berkshires. Yes, Sambo has given them corn plentifully; there it lies by them! But this is too plain a case; the pigs have the *teeth-ache, and they are broken off, too!* neither the wet nor the dry weather has caused the mischief here! And yet the pigs, like the cotton, have only *their teeth broken off!!* Poor Sambo! we leave him to explain to the world the rationale of this *root and teeth breaking policy.*

N. B. Cloud, M. D.

Macon Co., Ala., Nov. 1, 1843.

*Since writing the above, I see, in a report of the sitting of the Academy of Sciences for August the 14th, a paper was received from M. Dutrochet, on the production and ripening of fruits. This gentleman states "that the removal of the leaves of fruit trees, in order to expose the fruit to the direct influence of the air and light, is exceedingly destructive." I suppose he means destructive to the fruit. If so, his experiments would seem to corroborate this opinion.

From the Albany Cultivator.

LETTER OF MR. ELLSWORTH—BOMMER'S PATENT.

We invite the attention of the readers of the Cultivator to the annexed letter of the Hon. Mr. Ellsworth, chief of the Patent office at Washington, on the subject of patents, and the claims of Mr. Bommer in particular. There is no subject in the whole range of agriculture, of more interest to the farmer, than that of manures; and any improvement in its manufacture, by which its quantity and quality may be increased, will be received by them with favor. That manures made in the way recommended by Mr. Bommer, or according to the patent claimed by him, are of superior quality, no one acquainted with that method can doubt. But if, as Mr. Ellsworth seems inclined to suppose, it is only the French method, with some unimportant additions, so far as the making of the manure, or its quality is concerned, that method should be generally known, that all may avail themselves of its advantages, and we thank Mr. Ellsworth for enabling us to give the specifications a place in the Cultivator. We have given the large pamphlet, just published by Mr. Bommer, and containing an ample account of his method and its advantages, a copy of which he has kindly placed in our hands, an attentive perusal, and can safely say there are few, if any, publications on the subject there discussed, whatever may be their pretensions, which combine such a mass of practical instruction on the preparation and use of manures. Of the legality of the patent under which he is acting, we do not express an opinion; but we know that the method used by him, and described in the pamphlet, a copy of which is furnished every purchaser of a right, will make manure in any quantity, and of the best quality for almost every kind of cultivated crop. Of the French method, as described in the specifications, we are not competent to judge, having never witnessed its effects; we should, however, prefer purchasing Mr. B.'s book, in which the whole process is detailed.

—

LETTER FROM MR. ELLSWORTH.

Washington City,
Patent Office, Nov. 3, 1843.

Messrs. Gaylord & Tucker:—I noticed in your last number of the Cultivator, just at hand, a particular notice of Bommer's process—also his advertisement announcing "Bommer's manure method, secured by letters patent," and referring to "documents recorded in the patent office," to prove his rights. This advertisement has greatly increased the burden of answering requests for copies of "Bommer's Patent." Whilst I have studiously avoided expressing an opinion on cases pending or decided, yet as special reference is now made to the bureau to sustain the advertisement, and fearing that the public may be misled by my silence, I hasten to state the facts as they appear of record. Mr. Bommer, on the 12th of May, 1843, presented an applica

Archibald Smith
ufebr
Roswell Ga

tion for a patent for making manure. This application was duly examined, and rejected for want of novelty. No appeal was taken. The application was withdrawn, and $20, the usual sum allowed on withdrawals, paid to Mr. Bommer on the 6th of July last. No other application has been made by Mr. Bommer for a patent for similar purposes.* It may not be improper to state that Messrs. Baer & Gouliart, in June, 1843, obtained a patent for an alleged improvement on the method of making manure, patented in France by Jauffret, which said method, however, has not been patented in the United States, and is therefore free to the public. How far the public are restricted in the use of foreign inventions, may be ascertained by referring to the claim of the American patent, which, you will perceive, is restricted to the preparation of the *heap* and the mode of *applying* the lye to the same; the *ingredients*—in other words, the *lye itself*, not being claimed. That no injustice may be done to the parties concerned, I send you a copy of the American patent, and only add that Mr. Bommer has become an assignee for several States, under this last mentioned patent.

Yours, &c. H. L. Ellsworth.

Copy of Baer & Gouliart's Patent.—To all whom it may concern: Be it known, that we, Charles Baer and John Gouliart, of the city of Baltimore, in the State of Maryland, have invented certain new and useful improvements in the manner of making manure, which has been for many years practiced in France, and has been there secured by Letters Patent under the name of "La Methode Jauffret," and we do hereby declare that the following is a full and exact description thereof.

In the method of Mr. Jauffret, a pit or reservoir is prepared of sufficient size to contain the quantity of prepared lye which may be required by the nature of the establishment. This reservoir or vat is intended to be a receptacle of water saturated with decomposed animal and vegetable matters, and is further to receive the ingredients hereinafter named; such water is to be found on nearly every farm, and it may be augmented by the drainings of stables, by dish water, suds, and other substances of a like nature.

Mr. Jauffret, however, finally prepares his lye, by which the fermentation of the articles to be converted into manure is to be promoted, in the following manner, under various modifications.

For the conversion of from one to two thousand pounds of vegetable matter into manure, he takes about

200	lbs.	of night soil,
200	"	calcined plaster in powder,
50	"	wood soot,
20	"	wood ashes unleached,
60	"	quick lime,
1	"	common salt,
1	"	rough saltpetre,
150	"	lye or ferment drainings from a Jauffret manure heap.

These ingredients are, in many cases, to be replaced by others; this lye to be prepared 10 or 15 days before use. The quantity of materials above named, for the conversion of from 1 to 2,000 lbs. of straw or other dry vegetable stalks, will answer for about double that quantity of green vegetable matter.

In using this lye, the plan of Mr. Jauffret is to steep in it the vegetable fibres, which are to be acted upon by throwing them into the vat or reservoir containing it, and removing it thence at great labor so as to form a high heap in the vicinity of the vat, into which the drainings are allowed to run.

We have thus given a brief outline of the method of Mr. Jauffret, the same appearing necessary to the understanding of our improvements, which consist in our omitting altogether the excessive labor of steeping the materials to be acted upon in the lye, and elevating them from thence to the heap; and also in the preparation of a lye, which is equally effective with that of Jauffret, at much less cost, and which can be used immediately on its being made, thereby saving the delay of 10 or 15 days, which "La Methode Jauffret" requires.

We prepare a reservoir to contain the lye as usual, and in the immediate vicinity of this, we make our stacks or heaps of vegetable matter, which is to be converted into manure.

We give to the ground, where the heap or pile is to be made, an inclination towards the vat; if the ground is a firm clay, it may be merely sloped, and have shallow trenches dug on its surface to conduct the drainings back into the vat; or it may have a flooring of timber, brick or stone, as may be preferred, which may be so trenched as to conduct the whole towards a central drain.—When our platform or flooring is of clay, we cover the trenches and whole surface of it with brushwood or rails, so as to form a temporary grating that will support the weight of the heap, and thus insure a drainage, and the admission of air to the heap from below.

The materials to be converted into manure, we pile up on this prepared platform immediately as it is delivered by the carts, and this we sometimes continue to do until the heap has attained the whole height to be given to it, when, by the use of a pump, buckets, or other suitable means, we raise the lye from the vat and pour it on to the heap, continuing so to do until the whole mass is saturated; we, in general, however, raise the heap to a height of two, three or four feet, more or less, and then pour on a portion of lye, repeating this as the height of the pile is increased; this procedure obviates the necessity of lifting the whole of the lye to the full height of the heap.

The materials which we employ in making the lye, may be limited to the following, namely: cow, horse or hog's dung, or night soil, the urine draining from stables, and quick lime.—The ingredients used to be intimately mixed with a sufficient quantity of saturated water.

Two of the kinds of animal dung we have found to answer as well as a larger number. A perfectly good lye will be made by taking one barrel each of two of the species of dung, two of the urinary drainings, one of quick lime, and about 50 barrels of saturated water, which is then to be used as above explained.

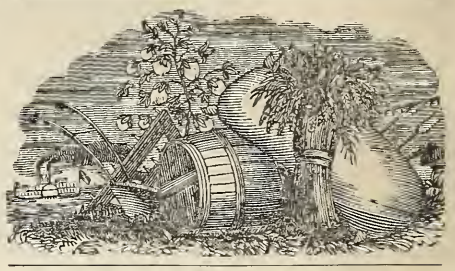
What we claim as our improvement on Jauffret's method of forming manure by the rapid fermentation of vegetable fibres, is, first, the forming of the said vegetable matter into piles or heaps, without its being first immersed in the prepared lye, and the subsequently saturating the same by the pouring on the lye in the manner set forth.

Charles Baer.
John Gouliart.

Witnesses,
Th. M. Abbett,
J. R. Abbett.
} (Patented June 24, 1843.

*Mr. Bommer informs us that on finding his own claim rejected, he was induced to make an arrangement with Baer & Gouliart, by whom his claim was again presented, and the patent secured in their names. —Eds.

Book Farming.—"I pity the stupidity of the man who thinks that if we use books, we must close our eyes against the light that is beaming upon us from other sources, or that we must become mere theorisers, and the victims of ruinous experiments. What! does a man loose his own common sense, his prudence and his judgment, whenever he takes up an agricultural paper, or opens a book upon husbandry? Cannot one make himself acquainted with the doings of others, without loosing his power to judge whether it would be well for him, in his circumstances, to copy their examples? Our brains are not so weak as this, The knowledge acquired from books does not make us all mad.—But if it did, there would be more zest and true enjoyment in the learned madman's course, than in that of him who has learned out, and who thinks that books cannot make him wiser. I ask what book-farming is? Common book-farming is, learning by means of books, new facts, opinions, results of experiments, modes of operation, and the using such parts of the information as can be turned to profitable account in our individual situations. If this be folly, we are content to be called fools. An agricultural paper will be worth to you every month, if not every week, more than its annual cost."



WEDNESDAY, JANUARY 24, 1844.

THE BACK VOLUME.

All new subscribers who may desire it, can obtain the first volume, neatly bound in boards, at one dollar the volume.

SEND IN YOUR LISTS.

As it is very important in regulating our edition to know what number of subscribers will probably be obtained, we beg our friends to send in their lists at the earliest possible day.

Mr. Baxter's Address.—In this number will be found the first part of the address delivered before the Hancock Planters' Club, in November last, by Eli Baxter, Esq., which we commend to the considerate attention of the reader. It abounds in home truths, which, if carefully weighed, cannot fail to be productive of much good. No planter, or head of a family, in Georgia, should omit to give it a careful perusal. Especially do we commend it to the youth—many of whom are growing up with erroneous notions of the true position of the agriculturist in society.

Improved Culture of Cotton.—The reader will find, in this number the third of the series of articles of Dr. Cloud, in defence of his system of the culture of cotton. Accompanying the article of the Dr., in the Albany Cultivator, is a drawing, representing the top and the 35th and 36th branches of a stalk of cotton cultivated by his system, which is certainly a very flattering testimonial of the success of his method.

The Doctor's gallantry has not only induced him to bestow the highest praise upon this drawing of the plant, which was executed by a lady, but has led him into an attack upon the correctness of all other delineations, among which we come in for a share, and the very beautiful cotton stalk in our head is compared to a pomegranate. Verily, this is not very flattering to the taste or capacity of the artist; but as we know not who he was, having copied it from a vignette on a bank bill, at a season of the year (mid-winter) when we could not obtain an original drawing, we shall not enter the list against our friend, the Dr., as the merit or demerit belongs wholly to another.

Curing Sweet Potatoes.—In our next, we will endeavor to afford J. L. Moody all the light on this subject at our command.

Agricultural Societies.—Again and again have we urged the necessity of forming Societies and Clubs in every county and neighborhood; and we are pleased to observe that in several counties, a proper spirit has been aroused. There are, however, too many counties in which no move has been made on the subject.—This state of things should not continue, particularly in a community where there is so much necessity for improvement; and we therefore repeat our solicitation to the friends of agricultural improvement, to organize Societies. Let not the indifference of a few self-conceited farmers, who think that "nothing can be taught them about farming," dampen your ardor in the good cause. You who are willing to profit by the experience and counsel of others, know the advantages to accrue from such Societies, and you should not faulter in the good work.

While on this subject, we beg leave to introduce the following very just and sensible remarks of the "New Genesee Farmer," which we commend to the attention of every friend of agriculture.

How to Sustain County Societies.—Those who desire to see their County Agricultural Societies increase in numbers, and in spirit and usefulness should take pains to *increase the circulation of agricultural papers* among the farmers of their county. In no other way can the object be so easily gained. All experience and observation have shown that *reading farmers* are the only ones that can be relied on to sustain and carry forward these grand means of improvement. Take your horses, then, ye friends of agriculture, and spend a day or two in calling on the farmers of your town or county, and induce them ALL to become reading farmers—they, or their children, will thank you for it hereafter.

Progress of Improvement.—From "E. W." of Narcoochee, Habersham county, we have the following flattering evidence of the lively interest which the subject of Agriculture is exciting among our citizens, from which we confidently predict the most satisfactory results. No citizen in Georgia has a finer opportunity to compete with the Kentuckian, in a large yield of corn, than "E. W." and we rejoice to see that he "*wont stay beat.*" This is the right spirit, and augurs most favorably for the cause of agricultural improvement. We hope he will enter fully into the rivalry, and give us, at the expiration of the year, the actual result—having accurately measured the land and its product.

We concur fully with our correspondent, in the propriety of converting much of the land in the Northwestern part of Georgia, into meadow lands and the culture of grasses. It is certainly a reflection upon our home industry and enterprise, that a large portion, (in fact, quite all,) of the Hay consumed in the Southern and Eastern sections of Georgia, particularly in the cities, is supplied by New England. The same remark will apply with nearly equal force in reference to Butter and Cheese. It requires time, however, to correct these things; and we doubt not, a few years hence, the hardy yeomanry of our Northwestern counties will supply many of the articles which are now obtained from abroad.—If we mistake not, "E. W." is a most worthy son of New England, and therefore speaks advisedly of the capacity of the "Mountain Hills" to produce Irish Potatoes. We think he might also have added, with great propriety, Apples and, perhaps, Pears. For all of these articles, a large amount of money is annually sent abroad—which, by a judicious system of economy and well directed agricultural industry, should be kept at home.

We hope "E. W." will frequently seek our columns to communicate his well digested practical views.

Mr. Editor:—I am pleased to receive the first number of the second volume of the "Southern Cultivator,"—a paper which no Planter should be without. It is exceedingly gratifying to hear, through the "Cultivator," what our brother farmers, in this and other States, are doing. Our friend in Kentucky beat me at raising corn last year, but I *wont stay beat.* We have lands in Georgia which will yield equal to their best in Kentucky. In 1842, I had a swamp cleared, containing about 20 acres: it was late in May before it was ready for planting; and, notwithstanding, there was much wet weather, (which prevented our cultivating it as it should have been,) it yielded from 80 to 100 bushels to the acre—besides, a fine crop of *pumpkins* and *melons.*

From many year's experience, I am convinced we should plant less, and cultivate our lands better. For years, I gave my attention to the raising of corn; but I find our lands can be used much more profitably, and at less expense—not in "digging" them up for gold, oh no!—but in sowing grass, and turning them into meadows. We can make as good hay, and as much as can be raised on their best meadows in the New England States. Off of 10 acres, we can make hay enough to winter 300 head of cattle and mules. The "Mountain Range," which is free to all, is inexhaustible, affording fine grass for cattle and horses from April to December.

A good farmer should have at least 50 milch cows, and make Goshen Butter and Cheese enough to supply your city.—Our mountain hills grow the *genuine Irish Potatoes*, equal in quality and quantity, to the Potatoes raised in Maine.—We ought, by all means, to send, from Habersham county, 1000 barrels Potatoes. The question is, why don't we do it? E. W.

Curing Corn.—The importance of this crop renders the subject of the best method of gathering and curing it, one of deep interest to the planter. We have, therefore, copied into this number, an article from the "Cultivator," which expresses a decided preference for the plan of cutting off the stalk at the ground, and curing stalks, corn and fodder all together. While we regard this plan as of very doubtful propriety at the South, where the crop generally ripens in September, long before frost, we nevertheless deem it of sufficient importance to give the views of the editors, and invite the attention of our planters to their consideration, with the hope that some of them will attest their applicability to this climate by actual experiments.

Fine Hogs.—J. D. Copeland, of Cracker's Neck, Greene county, writes us as follows:—

On the 28th December last, I killed a couple of "Land Pikes," or Common Stock Pigs. On the day I butchered them, they were just 21 months and 8 days old, and they weighed as follows—604 and 441 lbs., making together 1045 lbs. neat pork; and saved from both 207 lbs. of first rate lard. My manner of raising them is quite simple—they ran in my kitchen yard as pets until they were probably 6 months old; I then put them in a lot, and fed them on corn and slops from the kitchen occasionally, until some 4 weeks before I killed them—I then put them in a close pen, and fattened them on corn meal. From the above experiment, I am fully convinced that our native stock is good enough, if well attended to.

Best Method of Curing Corn.—Our Indian corn crop is one of the most valuable, if not *the* most valuable crop cultivated in the United States, and every thing relative to the best methods of growing and securing it are proportionably important. In securing Indian corn, two methods are commonly used; the first, is to top the corn, by cutting the stalk immediately above the ear, and this is usually done as soon as the grain is glazed, though some farmers scarcely wait for this. The second is to cut up the corn by the bottom as soon as the ear is glazed, bind the stalks and ears in small bundles, set them up, and let them stand till thoroughly cured, In the first method only the upper part of the stalk is saved for fodder, but the corn ripens finely, and nothing can be more beautiful than a field in which the husks have fallen from the ripened grain, and the thick golden ears give a promise of the rich harvest at hand. Still we prefer the second method, and that from ample experience of both. We have our corn cut up by the bottom, because in that way we save the whole of the stalks for fodder, and that is no unimportant matter to the farmer. In topping, only the poorest part of the stalk is saved, for if cut and cured properly, there is no more nutritious food for animals than the stalk of corn. It is true, when very large, cattle and sheep are unable to eat them; but if converted into chaff by a cutting machine, as they can easily be, there is no food eaten more readily, or with more profit. It is not hazarding much to say that there is more value in an acre of cornstalks cut by the bottom and properly fed out, than in an acre of ordinary hay, and no farmer can afford to dispense with such an item in providing for his stock. But the saving in the stalk is not all; experiments show that there is a gain in the grain of nearly 20 per cent in cutting by the bottom, in preference to topping. Experiments made by Mr. Clark, Judge Buel, and others, and recorded in the volumes of the Old Genesee Farmer, and the Cultivator, place the matter beyond a doubt. In one made by Mr. Clark, he found the yield per acre of the corn topped, to be 47 bush. 18 lbs., and the untopped 60 bush. 8 lbs. From some experiments instituted by ourselves several years since, it was ascertained that there was no difference of consequence in the product, when the corn was left on the untouched stalks till harvest, and when they were cut by the bottom after the corn was well glazed, but that both these methods gave a greater product than when topped in the usual manner. It is said that when corn is topped, and after the corn is gathered, that cattle will eat all that is valuable of the stalks as they stand in the field. This is certainly a mistake, as the most nutritious part, the main stalk itself, is generally left untouched by them. If the corn crop is well manured, as it should be, the cultivation of the season is an excellent preparation for wheat, and some of the best farmers of our country use the corn crop for this purpose. In this case cutting up by the bottom is indispensable for the getting in of the wheat properly; and if it is intended to follow the corn with spring crops, as is frequently done, such as wheat, oats or barley, it will be found that the absence of the large stalks that disfigure corn grounds when only topped, will greatly facilitate both the putting in, and the harvesting of these crops. For all these reasons, and the additional one, that it is only by cutting at the bottom that corn can be saved from the effects of early frosts when they occur, we are decidedly of the opinion that the corn crop of the country might annually be increased in value, were the method of cutting it by the bottom as soon as the grain is fully glazed, to become general.—*Albany Cultivator.*

REWARD OF INDUSTRY.—Among the competitors for premiums for the best improved farms at the Middlesex County Agricultural Fair, there were several instances of notable industry; we copy the following from the Report of the Committee, because we look upon it as evincing a degree of patient industry and marked success that cannot fail, by its example, of impressing upon the reader how vain is the conclusion which some arrive at, that, because difficulty may present itself, it cannot be overcome. The reader we think, will say with us, that though Mr. Walker received the *fourth* premium, his skill and industry would have entitled him to the first almost any where else than in a region where, from its rock-bound soil, men have to enact the part of men.—*Am. Farmer.*

"The farm of George W. Walker, of Marlborough, contains about 70 acres of land.—Nine years ago Mr. Walker purchased a very rough, rocky pasture, on one of the hills in Marlboro', containing 45 acres. At that time he was young and poor, with no capital but his labor to begin with, and of course he purchased on credit. He commenced cutting the bushes, digging out stone, and laying wall. He managed to build a barn 31 by 32 feet. He was in the habit of "working out" some portion of his time, and after he had finished his day's work, he would return to his own land, moon-light nights, and work among the stones till 11 or 12 o'clock. and then sleep in his barn. He has now 13 acres in a good state of cultivation. He has built him a house, laid 175 rods of stone wall, paid for his place, and has some money at interest, and all this has been done with his own hands, for the last two years, with the assistance of a boy now 9 years old. Let all poor young farmers look at this, and be assured that persevering industry will be sure to meet its reward.

The committee award to Mr. Walker the 4th premium of $12.

FARMERS' BOYS.—There is a wholesome change going on in public sentiment, which promises to do much for the improvement of the country and the condition of the people. We mean the change which is taking place among the young in relation to the great work of tilling the soil. A few years ago, and the young men left their fathers' farms as soon as they could get away from them—and the fathers themselves not unfrequently encouraged them in it. A hard hand and a sunburnt face were deemed poor recommendations in life; and more "genteel" modes of getting a living were sought by the young. But they are beginning to look at the matter in a different light. The dull times thro' which we have passed, lately, have opened their eyes to the fact, that after all there is nothing like a farmer to stand through all times, and they are quite content to stay at home. The result will be, that our farms will be better cultivated, and produce more; that large farms, which are not half cultivated, will be divided, and well husbanded; and that we shall have a large and virtuous population scattered all over our fertile hills.—*Nashua Telegraph.*

HINTS TO YOUNG FARMERS.—Consider your calling both elevated and important: never be above it, nor be ashamed of the frock and apron.

Never hire a man to do a piece of work which you can do yourself.

Instead of spending a rainy day idly, repair whatever wants mending, or post your accounts.

By driving your business before you, and not permitting it to drive you, you will have opportunities to indulge in the luxury of well applied leisure.

Never trust your money in the hands of that man who will put his own at hazard.

Take an agricultural paper, and some good family paper, and pay for them in advance.

Remember that economy and industry are the two great pillars of the farmer's prosperity.

Never run in debt without a reasonable probability of paying at the time agreed.

Never buy any thing at auction because the article is going cheap, unless you have use for it.

In December, reckon and settle with all those with whom you have accounts—pay your shop bills and your mechanics, if not promptly done at the time.

Put off no business for to-morrow that can be done to-day.—*Ohio Repository.*

LEAVES.—Among the many materials which at this season may be collected for manure, leaves are far from being the least valuable.—As soon as old Boreas has shaken down the withered foliage, harness up your team, and devote a day or so to hauling in a supply to be used as litter for your hogs, sheep, cows, horses and other domestic animals, and whose comfort during winter, is, like your own, promoted by the luxury of a warm bed. In this way, very important and valuable acquisitions may be made in a short time, and without an outlay of much expense.—*Maine Cultivator.*

A St. Louis paper tells a story of a disconsolate widower, who, on seeing the remains of his late wife lowered into the grave, exclaimed with tears in his eyes: "Well, I've lost hogs and I've lost cows, but I never had anything to cut me up like this."

AUGUSTA MARKET.

WEDNESDAY, P. M., January 24.

Cotton—The activity noticed in the market in our report of the 10th inst., continued, with an advancing market, up to the middle of last week, when prices having attained their maximum, 9¾ cents, the market became very quiet, and on the receipt of later accounts by a transient ship, on Friday last, the market gave way, and prices declined ¼ to ½ cent on all descriptions. The market is now very inactive, and we omit quotations, as both buyers and sellers seem disposed to await later accounts from abroad, which are expected daily.

Exchange—Checks are at par on Charleston, Savannah and New York. Central money is very steady at 3 to 4 per cent discount. Georgia 6 per cent Bonds are firm at 88.

GARDEN AND FIELD SEED.

A GENERAL assortment of fresh and genuine GARDEN and FIELD SEED, among which are the following:

Red and White Clover,
Blue and Green Grass,
Rye and Orchard do.,
Timothy and Herds do.,
Millet and Lucerne do.,
Seed Corn of every valuable variety,
Seed Wheat,
Buckwheat and Potato Oats,

Kept constantly on hand by the subscriber, all of which are offered for sale at very moderate prices. All orders, by mail or otherwise, executed with neatness and despatch.

SOUTHERN CULTIVATOR.

VOL. II. AUGUSTA, GA., FEBRUARY 7, 1844. No. 3.

COMMUNICATIONS.

SPARTA, February 1, 1844.

Mr. Editor—Plowing, though practiced by many, is little understood in this country. Indeed, so little importance is *generally* attached to it, that it is not unfrequently confided, either to the foreman, who is satisfied with any thing that pleases his master, or to an overseer, who is oftener ambitious to acquire a character for a "business man," which, in its literal signification, means to be ahead of every body else in the various operations of the farm, without reference to the quality of the work. Nor are these important personages singular in their notions. It is too often true, that they are encouraged, by the owner or employer, to glide over the farm as rapidly as possible, either directly by words, or by conduct which is unequivocal in its meaning—in bestowing praise when *much* work has been done, and in maintaining profound silence as to its *quality*. It can hardly be supposed in this day of general intelligence, that the subject of plowing is one upon which total ignorance prevails. But it is believed, that there are by far too many practitioners of this noble art, who practise it according to the method of their ancestors; who "trot up the hill and down again" as their daddies did before them. With all such, I have nothing to do on this occasion. They are too skillful to be instructed by "book farming;" too well versed in their business to be benefited by the experience and opinions of their neighbors, when obtained through an agricultural newspaper; too much engaged in watching the phases of the Moon to take "time" to read any thing relative to farming. It is sufficient for all such that they sow their wheat during the dark nights of October; plant their corn on the increase, and their potatoes on the decrease of the moon. Arguments with such are unavailing—successful practice alone can or will teach them.

The paramount object of all winter or spring plowing, is the complete pulverization of the soil—of summer plowing, to lessen the labor of weeding and cleaning the crop, and to make the earth permeable to the atmosphere—of fall plowing, the turning in the grass and weeds which have grown upon the land. It cannot be necessary to adduce reasons in support of the doctrine here laid down, that the earth, to do all that it is possible for it to do in growing and maturing plants, must be *effectually* pulverized to that depth, below which there is no food for plants. The examinations of the curious have discovered the fact, that the small fibrous roots of corn penetrate the soil, in favorable situations, several feet in depth, and by comparing these with similar roots of other plants, we readily conclude, that all fibrous roots grow as *deep* in search of food when it can be found, as the preparation admits and the atmosphere allows. And yet, in the face of this fact, how often do we see the most superficial preparation, if preperation it can be called? How often, as a necessary consequence of imperfect preparation, or what is frequently true, of no preparation whatever, do we hear farmers complain, that their land is so hard "they can't scratch it." A ten day's drought withers and ruins their crops; renders them miserable and unhappy, while their ungrateful feelings are excited against a kind Providence, who ever works for their good if they would but do their duty.

The quality and texture of soils are so various, as to render it impossible to lay down *particular* rules for our guidance in performing this work. Every practical farmer knows that different soils require different management.—But as a general rule, and one that is applicable to all soils, we should plow fully as deep as we find soil, and when practicable, use the much abused turning plow in preference to all others. It cannot be so successfully used, perhaps, on fresh land where there are innumerable trees and stumps, or where many stones abound, as the scooter or colter. But on every other description of land with which I am acquainted, I prefer it to any other plow in use in this section, whether it invert completely, or at an angle of forty-five, or any intermediate angle.—There are, however, hundreds of these plows in use, scarcely worth their weight in iron. An imperfect turning plow I regard as worthless.—The work of such may be passable to the eye merely, but will not bear the thrusts of the walking cane—a certain indication of bad plowing. They should be made so as to cut as deep at the point of the wing as at the point of the plow—the bottom of the furrow then will be like the bottom of a trench. The plowman, by holding it to its proper place, with such an instrument, can break up land as effectually as with the spade. The objections so often urged against this implement, are without foundation. Repudiation is the order of the day in farming as well as in politics. We inconsiderately imbibe opinions that are fallacious, and do not take the trouble to examine them closely, therefore we are prone to adhere to them. If *we* injure our lands in using them, *every* country upon the continent of Europe, that has doubled and quintupled its productions per acre, ought now to be *barren*—so ought the New England States. If they are too hard to the horse, the objection lies against the maker and not the implement.—Where properly made, they are drawn with more ease than any other plow performing the same work. After you have procured such plows as are described above, you will find the coulter, if the subsoil be clay, or clay abounding in disintegrated rock, of incalculable service, if run in the same track with the turning plow, as deep as your strongest horses can pull them. You are then certain that your land is thoroughly broken; that you have formed in the clay a reservoir for superfluous water, which will rise through the pores of the earth, in a dry time, to supply the wants of vegetation. Land so prepared is in a fit state to receive seed. A little drouth, under such circumstances, will be regarded as a blessing; land will be more mellow during the year; the crop will be more luxuriant in its growth, and more abundant at maturity. Such, at least, is the result of one year's experience. Without good plowing and manure, there can be no good farming on our exhausted plantations, if, indeed, any where.

GEORGIAN.

RAYTOWN, GA., February 1st, 1844

Mr. Editor—In perusing the pages of your excellent journal, I find a remedy recommended for the Hollow Horn. Although my experience on this subject is very limited, still, such as it is, I have concluded to give it to you.

For the hollow horn, my rule and practice has been, when a cow brute was observed with sunken eyes, dry nose, and *cold horns*, (which are sure signs of the disease,) is to bore the horn on the under side only, with a common size gimblet—for should the hole in the horn be made too large, the fly might get into the horn and create maggots, which would prove fatal. I do nothing more, unless the holes should close up with matter, I then insert a sharp pointed stick or broom straw, of a proper size, in them occasionally, in order to keep them open, until a cure is effected.

Under this practice I have never lost a cow with the hollow horn, while my neighbors, under different practices, lost many.

Respectfully, your o'bt serv't,

AARON W. GRIER.

Equally silly is he who is killing his land to fill his purse, with him who killed his goose to get the golden egg.

The labor of an editor's life is not so much what he has to write, as what he has to read.

ADDRESS

Delivered before the Hancock Planters' Club, by

ELI H. BAXTER, ESQ., *Nov.* 3, 1843.

Concluded from page 11.

How few planters know how much corn can be raised from one acre of land, well manured and well cultivated. In some sections of the United States they raise 100 bushels of corn, and 35 bushels of wheat per acre. In Hancock, there are some planters that do not gather 100 bushels of corn from 20 acres, and four or five bushels of wheat per acre. It is not surprising then that we have a decaying population. The State makes investments in stocks and internal improvement, with the view of realising interest. What interest, I would ask, has she received upon her bank stock and works of internal improvement? Millions would not cover her losses. Twenty-five thousand dollars expended annually in the way of premiums to agriculture, would treble your productions and population. Your taxes would be trebled without increasing its burden. Whose money do you ask for? Your own. Who pays the tax? Every cent of it comes out of the planter; for the profits of the mechanic and merchant are but profits upon the labor of the husbandman. Do not be put off with the hollow pretence of the politician, that the State is in debt, and injustice will be done the public creditors. It is the most efficient step that the State can take to fill her treasury and pay her debts. If the Legislature refuses this pittance, make it a question at the elections. If you would take half the interest in this matter that you do in the party questions of the day, which are of little or no interest to the public welfare, success would be certain to attend your efforts.

Agricultural papers and periodicals have been considered, by all intelligent men, as a means well calculated to bring about a reformation in agriculture. We patronize, with a liberal hand, the political papers of the day, that cost three times as much per annum as the Cultivator and Farmer's Register, but which do not afford half the instruction. One of the benefits arising from the circulation of these papers is, the increase of the public taste for the business of agriculture. The student will make but little progress in the sciences, if he has no relish for them; the student of law and medicine had better abandon them, if they take no delight in the study, their minds will doze and wander, while their eyes and lips drag lazily over their text books; the rich, successful and enterprising merchant takes as much pleasure in selling a yard of tape as the costly cashmere—to make a successful farmer, we must delight in the bleating of the lamb, the lowing of the cow, and the neighing of the horse; we must delight in the collecting and applying of manures, and in the growing crop. These papers are full of instruction that is substantial and profitable. To the cultivator of the soil they are of incalculable benefit; they come ladened to you, at a cheap rate, with the learning of the chemist, the botanist, geologist and philosopher; they bring to you, in a condensed form, the experience and learning of ten thousand heads, upon all the subjects connected with agriculture; they lay before you the agricultural experience of every age, climate, soil and country; they contain intellectual treats for the scholar as well as the illiterate farmer; they contain fine specimens of eloquence, in the addresses to agricultural societies, by the most distinguished men of Europe and America; they are a valuable dispensatory, without the unintelligible technicalities of the profession; they contain valuable and instructive matter for the housewife; in fine, they are literary omnibuses, well ladened with all the choice productions and discoveries of the age. These papers want patronage; they are not conducted by their proprietors with a view of personal benefit; they are the disinterested labors of the philanthropist for the benefit of his fellow creatures. No family should be without one; they are the cheapest and most valuuble periodicals of the age; no one will ever look back with regret to the money expended for the Southern Cultivator or Farmers' Register.

I come now to the discharge of the most important and interesting part of my duty—and I regret that it has not devolved upon one more skilled and experienced—the improvement and cultivation of our soils. I shall not fatigue your attention with suggestions as to the best mode of planting and cultivating our lands, only so far as it is calculated to improve or deteriorate. We could all make enough if we had good soils to do it upon. The question about which we all feel the deepest interest is, the practicability of renovating and restoring our old worn out lands to more than their original fertility. If we can, then it is clear that we occupy the most valuable lands upon the American continent; and the oldest of us will see the day when the waves of emigration that have been so long rolling from us, will set back to these abandoned lands. That it can be done, I feel as confident as that we shall have day and night, spring and summer, seed time and harvest.

The agricultural statistics of this country and Europe, are full of the most encouraging facts. Many portions of Europe that have been in constant cultivation for more than a thousand years, instead of being exhausted, have increased in fertility. Flanders, which is represented to be a sandy beach, has been so much improved that it is astonishing the world with the quantities of its products. Judge Buel, of New York, has imparted to a pine barren a fertility that is surpassing in its productions the rich lands of Tennessee and Kentucky. Lands that some years since could have been bought at four dollars per acre, cannot now be bought for one hundred and thirty-five dollars per acre. But we need not go to Europe or New York to be satisfied that we can improve our lands. You can be convinced of it in your own State, and in your own county. Mr. Thos. Whaley, a successful and intelligent farmer, is manuring annually every acre that he plants in corn and cotton. From fields that twenty years since were turned out as exhausted, he is now gathering luxuriant crops. We have only to commence the work, and success will attend the effort. We must make it a business, and be as faithful in attending to it as in planting and cultivating our crops. The first thing to be attended to in improvment is, to preserve our broken lands from being washed by the heavy rains. The first step in this part of the business is, to arrest the gullies and clay galls, which may be aptly compared to a cancerous affection upon the human system; they will, unless arrested, continue to dilate and widen, until the whole field is denuded of soil.—Ditching, when done upon correct principles, will effectually prevent their formation. But, unfortunately, all our fields are already gullied. Before we proceed to ditch, these gullies should be filled up and leveled. This can be done with little labor. The pine brush answers an admirable purpose for this object; and if they are not convenient, the fence row and the swamp will furnish you with an abundant material.

Ditches usually cross the gullies at right angles, and if they are not filled before the ditch is made, the water that they collect in times of heavy rains, will form such a body that it will break over the embankment of the ditches opposite the mouth of the gully. I have found it less difficult to fill up these gullies with brush, than to make the embankment high and strong enough to resist the volume of water that collects in them. Every farmer in this part of the State, should set about ditching his plantation. Appropriating one week with all hands, with horse power and the necessary implements, and you would ditch the whole plantation. They afterwards require but little attention to keep them in order. The ditches should be wide but not deep, with descent enough to carry off the water, without washing them deeper than they were made. Two inches every 12 or 15 feet, according to the length, is sufficient. They should never be made by the eye; the level and plumb should indicate the course and fall.

The clay galls, those offensive looking ulcers upon our fields, can only be arrested by being coated first with sand. To apply manure to them without sand, is a waste of labor and of manure. To restore them to sufficient fertility for cultivation is, in my opinion, too costly to be profitable; but a small quantity of sand scattered upon their surface, and then covered with brush, will arrest their further expansion, and nature will soon set them out with pine, which will become valuable for timber or fuel; or you may set them out with the plum tree, which will soon restore them to their original fertility.

In manuring there is a great want of system. We shall never do much at it until we make it a regular business; setting apart so much time of each year, with all our hands, to this branch of the business. If we will but economize our materials for making manure, we should have an abundance, not only to manure crops, but to keep in progress a permanent improvement of our lands. I am clearly convinced, that if we would but economize our cotton seed, and apply them jukiciously, every planter who makes four bags of cotton to the hand, would have a a plenty to manure in the hill, his entire crop of corn. This valuable manure is wasted in planting and in application. They should never be applied to wheat, as it takes too many to the acre to do much good. We loose immense quantities of manure for the want of fencing our sheep, hogs and cattle. The most of farmers pen their cattle, but there is no regularity about it, and instead of changing them at regular periods, they are permitted to occupy the same spot for the entire year, when by moving them ten times the quantity of land could be as profitably manured. Vast quantities of valuable material for making manure might be saved by throwing obstructions across the bottoms and small branches, to catch, at particular places, the vegetable matter and alluviums that are carried down in times of hard rains. The manure made by sheep and swine is as valuable as that made by the cow; yet there is not one farmer in an hundred that makes any manure from them.

We plant too much. Every man should resolve not to plant a line of corn unless he manures it; for one acre well planted and well cultivated, will make twice as much as an acre of the same quality of land badly planted and half cultivated; and a little manure will treble the products.

Every planter should have a meadow or pasture ground, so situated that his plow horses may feed upon it at night. I have ascertained that a plow horse will do better when he can have pasture every night, with two-thirds food, than he will do kept up all the time with corn without allowance. With this pasture we can do with one half of the corn; for when the horse is not at work he can do without any corn.

Too little attention is paid by planters in this State, to the character of their soils in planting their crops. Upon every plantation there is some portion better adapted for cotton than others. Such fields or spots of land should be reserved exclusively for cotton; alternating them with crops of small grain instead of with cotton, corn and then small grain. The same course should be observed with lands favorable to corn. Land should never be planted two years in succession in cotton, unless they are level lands, which should always be taken into consideration in setting apart particular fields for cotton. The surface of the cotton field being bare all winter and summer, it is much more subject to be washed by hard rains than if in corn.

There being but little forest and no swamp land, it has become very costly to raise pork. To superscede the necessity of feeding so much corn to hogs, I would advise the sowing of rye and oats for them in winter and spring; and as an additional substitute, I would recommend every corner of fence that is permanent upon

the plantation, to be set with the plum, peach and apple tree, which, if judiciously selected, would furnish food for your hogs from May until November.

Upon most of our plantations timber for fencing has become scarce, and where it is plenty it is inconvenient. The repair of our fencing has become one of the most laborious duties in our agricultural labors. The time that intervenes between the laying by and gathering of the crop, and between the gathering and the planting, which we should appropriate to the collection and making of manure, is devoted to the repair of fences. It has become to us highly desirable to adopt some system that will save labor in this department of our business. From a suggestion in the Cultivator, I am satisfied that a great deal of labor can be saved by ditching. The time employed in cutting, mauling and hauling rails to the places where wanted, would make ditches which would be permanent, and require no repairs upon our descending grounds, as the rains would keep them from filling up. Ditches, with the embankments made with the earth taken from them, with half the rails around, would make a fence that would answer as good a purpose as the best of fences, made in the usual manner.

I would suggest to every farmer the value of agricultural memorandums—such as a note of the time and manner of planting different fields; the quantities of manure applied; the character of the seasons, and their productions. Independent of the pleasure which we will derive from it as a paper of reference in after times, it will constitute a sort of agricultural thermometer, that will tell us at the close of each year, the progress we have made in the great work of renovating our soils.

Before we can make much progress in agricultural improvement, I consider it of primary importance to create in the mind of the landholder, an attachment to the soil upon which he lives. The plan which I propose for its attainment, has been suggested by an act which you will find in your own statute book. The member who introduced that measure is deserving of the highest commendation, and the act itself will be considered, in all time to come, as the brightest spot in the legislation of the State. I allude to the act which exempts from sheriff's, sale, the mansion house of the debtor and 20 acres of land. I unhesitatingly recommend to the agricultural class, a law exempting from sale all the lands of the debtor connected with his mansion, provided it does not exceed five hundred acres. To make it prospective, will remove all constitutional objections. You need not shrink back, startled at the boldness of the proposition. It will be the law of the State within a short period of time. It will receive a cheering response from every landholder in the State. The professional politician, who is always upon the watch for the popular current, will embrace it, and it will carry him into power. It is a cord that will vibrate pleasantly upon the feelings of every husband and father; it will smoothe their dying pillows, for the widow and orphan will have a home! It is a constitutional and inherent feeling of every man to desire a home; it is his constant aspiration. Who has not heard the song, "Home, Sweet Home," and not felt electrified at the truth and beauty of the sentiment, "Though ever so humble there is no place like home?" What would so effectually attach men to their lands, as the reflection that they have a home, a permanent home, a home that no vicissitudes can take from them; a home in old age; and, above all, a home for their destitute widows and helpless orphans? These considerations cannot fail to give them, hallowed as they are, an increased endearment that they never possessed before. In a political point of view this measure is deserving the most favorable consideration of the statesman. It will effectually arrest the decay of population, and we should no longer see the tide of population rolling out of our borders; it will invigorate and stimulate the arm of industry. The poor man of every pursuit will be encouraged to increased industry and economy, to procure the comforts of a permanent home. It will bring into action every motive and inducement that can prompt men to beautify their homes and fertilize their lands.

It is the labor of the husbandman that fills the granaries from which all are fed. Depress his business, and the hammer of the mechanic becomes silent for the want of employment; the machinery of the manufacturer ceases from its labors; and the sails of commerce are no longer unfurled to the breeze, but idly flap at their moorings. The manufacturer works short time, and no serious inconvenience is felt by society; but let agriculture cease from her labors and what would be the consequence? Industry would stagnate in all its branches; society would be overwhelmed with the distress of famine, and dessolation would overspread the land.

Judge Buel, in an address delivered before the Agricultural Society of New Jersey, expresses in beautiful and admirable style, the influence which agriculture exercises upon the political institutions of every country:—"I need not remind this enlightened assembly of the important bearing which the condition of our agriculture, and our agricultural societies, have and ever must have upon our political destinies.—The farmers of our country will be the last class to be corrupted by the smiles and blandishments of power; the last class to part with republican habits, to degenerate under the baneful and enervating influence of extravagance, dissipation and fashion. The higher the condition of agricultural improvement, the greater will be the intelligence and independence of the agriculturist, and the stronger his inclination and influence in perpetrating the virtues of our revolutionary fathers, and in maintaining in their purity the institutions which they established, and in defending them, if need be, from foreign and domestic foes. Cherish their interest above all others; enlighten it, encourage it, honor and reward it, for it is the palladium of our freedom."

All must acquiesce in the correctness of these sentiments. Their truth is established by the history of every state of ancient and modern times. We all admire and adore our form of government—it is the perfection of human wisdom—we cannot improve it; but every patriot is anxious for its perpetual preservation. American citizens should keep fresh in their recollections, the opinion of the philosophic historian, that there was a point of elevation beyond which States could never go, and that when they reached that point, they could not remain stationary, but began to decline until they were finally blotted from the catalogue of nations.—The history of States would seem to establish the truth of the historian's opinion. How mortifying to the patriot and statesman! All the republics and kingdoms of ancient times have passed away. "Where are their cloud caped towers, their gorgeous palaces?" Science and the arts are important to preserve them. No one can now tell the spot where Demosthenes poured forth the thunders of his eloquence, to awaken his countrymen to a sense of their danger from the usurpations of Philip. Where is the Senate and the Forum, where Cicero so repeatedly, in strains of matchless eloquence, addressed his enraptured countrymen. Many of the states of Europe are manifestly upon the decline. Spain is nearly consumed by those internal fires that have been kindled and kept constantly burning by the collision of her domestic factions. France, after the battle of Waterloo, but for the jealousy of neighboring States, would have ceased to exist as a nation. History teaches us that science and eloquence, the arts of peace and war, cannot give stability to States; that the popular axiom in politics, that "intelligence is the life of liberty," is not entirely true, if we are to understand from it, that it can establish and preserve free institutions. It is an important auxiliary, but there is another element more necessary to the preservation of the public liberty than intelligence—it is public virtue. I do not mean public virtue as taught by some of the schools, but virtue founded on that perfect and sublimated morality first proclaimed from Mount Sinai, and afterwards taught by the illiterate fisherman. Public virtue is particularly necessary to give stability to free institutions. In popular governments, where every citizen participates in its administration, each should possess the qualification necessary for the performance of this high privilege—each citizen should be intelligent, moral and independent.

You will never witness the mortifying spectacle at your elections, of seeing the unprincipled demagogue dragging up to the polls the independent land holder. If the people of free States are virtuous and independent, they need have no alarm for the elevation or depression of particular parties. Confiding in the truth, the great republican truth, that man is capable of self government, it is immaterial to which political party the people confide its administration. Being virtuous and independent, they will necessarily have faithful and capable agents, who will be hurled from power so soon as they cease to administer it in its purity. Agriculture is particularly favorable to the improvement of these high qualities. The husbandman asks no favor but from his maker; he asks no favor of the government, but the protection of life, liberty and property. Interest makes him the friend of the laws, and to him the most hateful and detestable of all despotisms is in the government where the law is not supreme.

Employment is the great preservative of morals. What gives so much employment to man as agriculture? Where there is plenty of employment there are no paupers, and but little crime. Every thing around the husbandman is calculated to improve and refine his virtuous feeling. He can make every thing in nature subservient to his moral improvement, "from the loud peal of thunder to the chirp of the insect; from the lofty oak to the spear of grass." "He can find tongues in trees, books in murmuring brooks, sermons in stones, and God in every thing." Who can look upon the rich harvest field, without having his thoughts elevated to Heaven? Who can witness the ceaseless return of the seasons, and mark their delightful influence upon the animal and vegetable part of creation, without feeling a sense of gratitude and love for that Being who has been pouring upon his creature, ever since the creation of the world, one continued stream of mercies and blessings. These associations can but refine and purify their affections, and enforce the obligation of that great moral precept, the foundation of all public and private virtue, "love and good will to man."

The want of this great element is signally manifest in the history of the French Revolution. The reader of history, after he closes the last chapter of the French revolution, will involuntarily pause and inquire, why a revolution, kindled through the joint influence of oppression and the spirit of liberty, which progressed so successfully, and promised so much for the liberty and happiness of man, should have terminated so disastrously. It was clearly not for the want of intelligence, civilized refinement, and capacity for war. At its commencement and during its progress, France was the great centre of politeness and refinement; she was illuminating the world with the brilliancy of her discoveries in chemisty and philosophy; the splendor of her military achievements were electrifying and startling all Europe; the great genius of her captain prostrated and leveled mountains, and transferred his legions and munitions of war from kingdom to kingdom, as by magic; he planted his standard in almost every state in Europe, and the French Eagle perched in triumph upon it. History has disclosed the cause without assigning it as the reason. Intoxicated with her success, France declared there was no God! All moral restraints were removed. The virtuous citizen was os-

tracised, and the government of the country devolved upon the sansculotte of the city and town. Atheism let loose upon society all the bad passions of the human heart; avarice, lust, revenge, envy, malice and cruelty, riotted upon the lives, property, rights and liberties of her people.—The streets of Paris become slipery with the blood of her people. Humanity and reason stood aghast, intimidated and silenced by the fierce cry of the infuriated populace. Thus we have seen a revolution, the most remarkable in modern times, for the want of this great preservative element, public virtue, terminating without accomplishing any thing for the amelioration of man. In fact, the example of the French revolution has been a drag-chain upon the spirit of liberty, and has thrown back for a century, the march of free and popular institutions.

I cannot permit the occasion to pass without adverting to an incident in the American revolution, that illustrates the strong attachment which the possession of a home gives to independence and freedom. At the darkest hour of the American revolution, when every patriot was almost despairing, the British General issued the proclamation, offering freedom and protection to all those who would come forward and subscribe the declaration of allegience, a person familiar with the scenes of those days says, "That even members of Congress, men of worth and influence, many who had held office, in despair gave up and subscribed the declaration; but that the men in the middle classes stood firm. And who constituted that middle class that stood firm in that eventful and trying crisis? They were mostly the small landholders!'

It then becomes the highest duty of the State to offer any inducement for the occupation and improvement of the soil; to make, if practicable, every citizen a landholder; for if ever the political institutions of this country are placed in jeopardy and peril by an enemy, either foreign or domestic, the great mass of landholders will be the first to rally to their rescue, and the last to abandon them.

Prevention of Smut in Wheat.—At a late agricultural meeting in Sussex, Eng., John Ellman, Esq. related the following account of an experiment in preventing smut in wheat. He took four sacks of smutty wheat, sowed one sack of it with brine only, as strong as he always made it, to bear an egg as large as a shilling; he sowed another with lime only; he sowed the third sack with brine, strong enough to bear an egg, and then let it lay in lime all night; and the fourth he sowed without any thing.—The result was as follows: where the brine only was used, every now and then there was a smutty ear, still not many; where the lime only was used, there was much about the same quantity of smut: where the lime and brine was used, there could not be found a single smutty ear; and where nothing was used it was a mass of smut.

Useful Recipe.—I send you below, Messrs. Editors, a receipt for making a composition which will render wood entirely incombustible. It is very simply prepared, and quite easy of application, being used the same as paint with an ordinary brush. A good coat of it applied to the floor under the stoves would be an excellent precaution.

Take a quantity of water, proportioned to the surface of wood you may wish to cover, and add to it as much potash as can be dissolved therein. When the water will dissolve no more potash, stir into the solution, first a quantity of flour paste of the consistency of common painter's size; second, a sufficiency of pure clay to render it of the consistency of cream.

When the clay is well mixed, apply the preparation as before directed to the wood; it will secure it from the action of both fire and rain. In a most violent fire, wood thus saturated may be carbonated but will never blaze.

If desirable, a most agreeable color can be given to the preparation by adding a small quantity of red or yellow ochre.—*Buffalo Com. Adv.*

From the New Genesee Farmer.

RESULTS OF EXPERIMENTS—SCIENTIFIC FARMING.

The following statements, from the N. York Tribune, afford a good illustration of the importance of scientific experiments in agriculture, and the necessity there is that Experimental Farms should be instituted for the purpose. In relation to the experiment with lime and charcoal, it is important that the previous character of the soil should be accurately understood; for on some soils these substances would be of very little use. It is also important for us to know what is the difference in effect between the oyster shell lime and common stone lime. We apprehend it is not great.

"We remember to have been much struck at the recent exhibition at Niblo's, under the auspices of the American Institute, with the remarkably fine specimens of cereal grains and of garden vegetables, from the farm of Mr. Pell, and can now understand their marked superiority.

"At a meeting of the Farmers' Club, Mr. Meigs stated that Mr. Pell, of Ulster county, made a statement at the Repository relative to his experimental farming, from which it appeared that he found benefit from the use of oyster shell lime, using 300 bushels per acre. That in addition he had employed 25 bushels of charcoal per acre. That on this charcoal dressing he obtained, last summer, *seventy-eight bushels and twenty-four quarts of wheat per acre.* That he had 20,000 apple trees in full bearing. That in dry weather he had applied lime freely at the roots—found that this preserved the verdue and growth, when the neighborhood was much injured by drought. That he had cut wheat two or three weeks sooner than his neighbors; and when the root of the straw began to turn brown, and when, by the pressure of the finger and thumb on the grain, the milk would fly out.—That this wheat weighed 64 pounds per bushel. That he sold it for seed at $1, when ordinary wheat was 87½ cents. That he cut clover and housed it on the same day—sprinkling about a bushel of salt over every load. That this clover retained its green color, and was preferred by cattle to that saved the old way. That he dipped a sponge in ammonia, and applied it to the worm nests on his trees, and banished them completely. That he has sent 4000 barrels of apples to market, many of which go to London, and there sell for $9 per barrel. That he employed a man from Vermont to engraft 10,000 apple trees, for $150; that this man brought a company of men, of whom two sawed off the proper limbs, two made the proper incisions (two of them) in the branch, two more inserted the grafts, two more applied a compost of wax, tallow and rosin. That out of the 20,000 grafts not one failed."

Since the foregoing was in type, we found the following in the Albany Cultivator:

"EXPERIMENT WITH CHARCOAL.

"*Messrs. Editors*—I mentioned to you last spring, that I had sown 52 bushels of charcoal dust to the acre, on wheat, and would give you the result of the experiment. In order that my promise might be fulfilled, I selected a corner of a 25 acre field of wheat, containing by survey two rods. The grain was harvested while in the milk, on the 17th of July; thrashed, cleaned, and measured on the 21st, yielding 31 quarts and 1 pint, or 78 bushels and 24 quarts to the acre. As the above fact may appear incredible to many wheat growers, I enclose the survey, and certificates of two of my men, who measured it.

"I have grown cuttings of the Camelia japonica, soft wooded geranimus, cactus, wax plants, &c., in pure charcoal dust, without any admixture of earth; likewise corn, beet, carrot, and other seeds, and believe it to be the most valuable substance now known as a manure, being pure, incorruptible and lasting.

"Yours respectfully,

Robt. L. Pell.

"*Pelham, Ulster, Co., Nov.* 20, 1843."

"I, M. W. Powell, surveyor, hereby certify that I have measured the ground herein described, beginning at an apple tree, and running a northwest course 95 links, thence a southwest course 50 links, thence east 30 links to a line to the north angle, thence east 70 links to the place of beginning; the line from the base to the north angle being 26 links, containing 2 rods, which is a portion of R. L. Pell's wheat lot No. 2.

M. W. Powell.

Affirmed before me, on the 15th day of July, 1843. M. M. Keller, J. P.

We, Patrick Farrell and Leonard Latten, hereby certify that we gathered, thrashed, cleaned and measured the wheat grown on the above described two rods of ground, belonging to Robert L. Pell, Esq., of Pelham, Ulster Co., and the yield was 31 quarts and 1 pint, dry measure: we believe if the gleanings had been threshed, there would have been one bushel.

Patrick Farrell,
Leonard Latten.

From the Farmers Monthly Visitor.

Qualifications of Farmers' Wives.—A writer in the Visitor for May, speaks of the great importance of females, especially the wives of farmers, being acquainted with all the duties of a domestic kind, and bestows high encomiums upon her "who rises with the lark," prepares suitable food for her family, &c. My opinion perfectly coincides with his as to the importance of a farmer's wife knowing, superintending and assisting in her domestic duties, so that every thing be done as it should be. Yes: I would praise her for her skill in preparing the hot cakes and early breakfast. Yet I would contend for the superiority of her who, with neatness and skill performs her routine of domestic duties with alacrity, in order to spend a few hours in useful reading, that she may impart light and knowledge to those around her, thereby enriching her own mind, and the minds of her children, so that they may become useful members of society.

Time is making vast ravages among those who take an active interest in the welfare of our country. Who are to take their places? Shall we look for them in our large cities? Do not many of their young men live in idleness and dissipation? Are they accustomed to that close application to study and business which is necessary to discipline their minds and fit them for important places in government? Where, I say, are we to look for our future legislators and statesmen, but among the sons of our honest yeomen?

And does not the formation of their minds depend upon their mothers? Are not the first impressions the strongest and most lasting?—And are not those received from the mother? Is not the child taught the love of good and evil, and the love of God and his country, from his mother? Does he not imbibe her sentiments and feelings with the first dawnings of reason? How important, then, that she be intelligent, and that her sentiments be correct and her judgment good.

The business of farmers require constant attention through the busy seasons of the year; they have but little leisure for intellectual pursuits, or instruction of their children, and the wife who spends some portion of her time in useful reading, and imparting the information thereby gained to those around her, does abundantly more benefit her family, than she could possibly do in raking hay or picking potatoes. We are craatures of imitation—monkey-like. If a child sees his mother take a book, he likewise will take one. If she speaks of what she reads, he will likewise, and so imprint it on his memory. The influence of such a woman is great. It will be felt around her, and it will tell upon a generation yet unborn.

Women possess quicker sensibilities and finer feelings than men, and they have more leisure for improvement. Let them improve their time to the best advantage, and we shall have an intelligent community.

A man's mind is not very likely to expand or

be elevated, whose wife can talk of nothing but feeding the ducks and chickens, though the ducks and chickens *should* be fed, and fed *often*, too. ACCA.

A WIFE WORTH HAVING.—We were favored a few weeks ago with an interview with Mr. Harvey Ford, of Winchester, Litchfield county, who called in to pay his subscription for the fourth volume of the Farmer's Gazette. Mr. Ford's farm lies principally in the town of Goshen, and like most of his townsmen, he is a thorough-bred dairy-man, and employed in producing the famous Butter and Cheese, which has acquired such an enviable name all over the land.* His operations in this are not so extensive as many of his neighbors, he keeping only on an average twenty cows; but the products of his dairy are of the best quality, and always demand the highest price in the market.—The first premium on Cheese was awarded to him by the Hartford County Agricultural Society in 1842.

Feeling highly gratified with the opportunity of an interview with an intelligent farmer from that section of our State, we exercised our Yankee prerogative, and asked Mr. Ford a great many questions in relation to his business. We ascertained that he had occupied his farm about sixteen years, during which time his energies had been directed chiefly to the single object of producing a first rate article of butter and cheese; these richest of all the products of agricultural labor. Among other things, we asked him what quantity of these delicious articles his farm produced annually, and how much he usually laid out for labor, &c. From the answer we learned that Mrs. Ford had performed almost the entire labor with her own hands, and that Mr. F. had a regular account at home of the quantity made each year, the price for which they were sold, &c. At our solicitation he promised to send us a correct statement of his books.—Prompt in the fulfilment of his engagement, we received from him, a few days since, a written statement from which we copy as follows:—

108,807 pounds of butter and cheese, exclusive of what was used in the family, and some sold to families of which no account is given, made by one woman, (Mrs. Ford,) during a term of sixteen years past—except a very small proportion made by others during short intervals while she was absent or out of health. The amount of money for which these articles were sold, was $8,340 80. This is an average of 6,800½ pounds of butter and cheese per year, selling for $521,30; and all made by the hands of one woman.

Such a wife is an invaluable treasure to her husband. What would some of our modern fine ladies say to this? What would the *fashionable* Miss think, if told on her bridal eve that she would be required during the next sixteen years to manufacture 7,000 pounds of butter and cheese every summer! If told that instead of spending all her husbands money for silks and laces and trumpery, to enable her to make a great *bustle* in a ball room or at a fashionable watering place, she would be expected by her own industry to add $500 a year to the wealth of the family, how would her delicate hands be raised in horror at the thought! And yet our word for it, Mrs. F. has been a happier woman for 16 years past, than the most tightly laced and profusely bustled dandisette who promenades Broadway or Chapel street. We are almost inclined to read a homily on female education—but it would be out of our appropriate sphere.—*Conn. Far. Gaz.*

* The "Goshen Butter," which has acquired such a high reputation, we rather think is made in Goshen, Orange county, N. Y. We suspect there must be some mistake in the statement above.—[*Eds. Chron. & Sent.*]

OIL DESTRUCTIVE TO PLUM TREES.—Mr. David Tomlinson, of Schenectady, informs us that two of his neighbors lost quite a number of valuable plum trees the past year, by applying oil to caterpillers in the spring, to destroy them, as they had seen recommended in some publication.—*American Agriculturist.*

EQUIVALENT OF VARIOUS PLANTS TO HAY, &c.—We find the followidg table of equivalents in Smith's translation of Burgher's Economy of Farming:

100 lbs of good hay are equal to
90 lbs of clover hay, made when fully blossed.
98 lbs of do. made before it blossomed.
98 of do. second crop.
98 lucerne hay.
89 sainfoin do.
410 green clover.
467 vetches or tares, green.
275 green Indian corn.
374 wheat straw.
254 rye straw.
164 oat straw.
353 pea stalk.
201 raw potatoes.
175 boiled do.
339 mangel wurtzel.
504 English Turneps.
276 carrots.
308 ruta baga.
54 rye, (grain off.)
46 wheat, do.
59 oats, do.
64 buckwheat, do.
57 Indian corn, do.
45 peas.
55 beans.
60 horse chesnuts.
68 acorns.
62 sunflower seed.
69 linseed cake.
105 wheat bran.
109 rye bran.
167 wheat and oat chaff.
179 rye and barley chaff.

An ox requires 2 per cent of his weight in hay per day; if he works, 2½ per cent. A milch cow, 3 per cent. A fattening ox, 5 per cent at first, 4 per cent when half fat and afterwards. Sheep, when grown, 3½ per cent of their live weight in hay per day.

SUCCEISFUL CORN CULTURE.—We subjoin a short communication made to the Central N. Y. Farmer, giving a very pleasing account of the yield of an acre of corn in Oneida county, N. Y. We say pleasing, because neither the quantity of manure applied nor labor bestowed were large. We call attention to the *manner* of preparing the land and applying the manure, because we believe that the success of the crop was owing in a great measure to the circumstances of deep plowing and a division of the manure between the subverted and surface soils. We can the more readily incline to this opinion, as there was nothing very extraordinary in the *quantity* of manure applied, nor in the amount of labor bestowed to the after culture of the corn.—*American Farmer.*

Gentlemen—On the farm on which I reside, (belonging to S. Dakin, Esq.,) we cultivated the present season, one acre of corn. The land had lain in grass for many years, and for several of the last had produced but a light crop.—In the spring of 1842, it was plowed up, and received about fifteen loads of manure, and planted with potatoes—the crop only a moderate one. The last spring the piece was plowed twice, as deep as could be done conveniently, and previous to the last plowing, received twenty to twenty-two loads of long manure—the precise number I cannot state as no memorandum was made at the time. After the plowing, eight loads of compost manure were spread on the surface, and the piece harrowed and marked three feet apart each way—and planted the 19th day of May with the common large eight rowed corn, steeped in saltpetre water, and dried in time. It was hoed twice, which kept the ground tolerably free from weeds as it was kept clean the year before. It was harvested on the 19th of September, cut up at the ground and put in shocks, and husked in about ten days afterwards. The product was 182 bushels of ears, equal, as usually calculated to 91 bushels of shelled corn. Cost in labor, 28¼ cents per bushel.

Last season we cultivated something more than double the quantity of land, naturally the same kind of soil, but which had been many years under the plow, and lightly manured, and obtained 200 bushels of ears, which cost 47½ cents per bushel of shelled corn.

CYRUS INGALLS.

FALSE ESTIMATION OF AGRICULTURE.—The first obstacle in the way of agricultural improvement, is the low estimate which has been put upon this calling. It has too often been regarded as an employment that requires nothing but physical power—mere brute force; and consequently, if a young man exhibited any considerable degree of talent, he must be put to some other calling. The natural tendency of this has been, to degrade agricultural labor, and to impress upon those who had any aspirations after distinction, the impolicy of groveling in the dust, as cultivating the soil has sometimes been regarded. The effect of this has been to draw talent away from agriculture, and to create an impression that the calling was not as respectable as some others. Many a young man has been driven from agriculture, and brought to ruin by this cause. And if it were not ungallant, I would say that some of our young women, faultless in every thing else, have been so far deceived as to prefer a husband employed in other pursuits than agriculture. But the reverses which have attended other pursuits, will, I trust, soon teach them, that the permanent home of the farmer's wife is greatly to be preferred to the changing abode and variable fortune of many other classes of our citizens. * * * * Agriculture is no mean employment. It was the first into which our race entered, and it is the last which can be abandoned. It has commanded the attention of some of the wisest and best men of ancient and modern times. Cincinnatus, renowned in war, was not ashamed to follow the plow; and the estimate which posterity has put upon his worth is such, that the *farmer* has thrown the *general* into the shade. And in our own country, to mention but one example, the Farmer of Mount Vernon was the Father of his Country. Who, then, would disdain a calling pursued by the wise and the good—a calling essential to the well-being of society, conducive to public virtue, promotive of health and happiness, and one to which Washington was proud to retire, from one of the highest stations ever conferred on man. But modern discoveries have made agriculture more attractive than formerly. Now the application of science renders it an *intellectual* employment; so that the laborer may improve his mind while improving his soil, and cultivate his heart as well as his farm.—*Correspondent of N. E. Farmer.*

THE PEACH.—With the fertile soil of our country, we have but little difficulty in growing peach trees until they are three or four years old, when they are attacked by the worm in the root, or a disease called the yellow, and frequently by both. In either case the tree dies in two or three years.

The following remedies have been found perfectly successful in preventing the worm in the root: When a tree is first set out in the orchard, apply three quarts of fresh or unleached wood ashes, and add ashes every spring: Another method is to pour chamber-lye around the roots of the trees several times during the spring and summer.

The method pursued by Mr. Pell, of Pelham, Ulster county, N. Y., is to put one half peck of fine charcoal to the roots of each tree when first set out in the orchard, and adding a quantity each spring.—*B. G. Boswell, Philadelphia.*

HOW TO HAVE A SHARP RAZOR.—Take a strop of thick harness leather, the size you want for a strop and fasten it at each end upon a piece of wood, then rub upon its surface a piece of tin, (any tin dish will do,) until it is smooth.—Strop your razor upon this, and you will find it worth all the patent strops that were ever invented.—*Selected.*

WEDNESDAY, FEBRUARY 7, 1844.

THE BACK VOLUME.

All new subscribers who may desire it, can obtain the first volume, neatly bound in boards, at one dollar the volume.

SEND IN YOUR LISTS.

As it is very important in regulating our edition to know what number of subscribers will probably be obtained, we beg our friends to send in their lists at the earliest possible day.

PLOWING.—In welcoming "*Georgian*" to our columns as a contributor, we cannot omit to invite the reader's attention to his article on plowing, which will be found in this number. There is no portion of agricultural industry requiring greater attention and care than the manner in which the plowman discharges his duty, and yet we believe that few, very few, of our planters regard it of sufficient importance to bestow that attention so necessary to its proper execution. To all those, therefore, who think it of little consequence whether their lands be well or imperfectly plowed, we commend the remarks of "Georgian;" nor indeed are there any portion of our planters who may not be benefited by the learning and practical observations of such a writer, who, we sincerely hope, may continue to enrich our columns with his views upon all subjects pertaining to agriculture.

OBSERVATIONS ON SWEET POTATOES.—I have observed in using my potatoes out of the hill or bank, that those in the north side of the hill had sweated the most, the east and west sides did not sweat quite so much, while the south side was perfectly dry, and much more rotten than any other portion of the hill.

Now for my mode in putting the potatoes in the hill: In the first place, I excavate to the clay or subsoil, in a concave form; I then place pine bark so as to cover the bottom of my excavation, with the outside of the bark upwards; I then fill up with potatoes until the hill, which is about five feet in diameter at the surface, is about two feet above the surface; then cover the potatoes with pine bark, taking care to put the inside of the bark next to the potatoes; out side of the bark I place a layer of crop grass, and then cover up the hill, three or four inches thick, with dirt, leaving a hole at the top of the hill sufficiently large as a ventilator, say six or eight inches in diameter. Generally my potatoes keep tolerably well.

This is one mode: now for another which I have sometimes tried. In the first place, I throw up the dirt so as to raise an embankment some six inches high, then cover with pine bark, and go through the same process as with the hill above. In putting my potatoes away in this manner they dry rot, and I cannot succeed. My object is now to cause my potatoes to sweat on the south side of the hill, and then there is no difficulty in keeping them sound.

Will you, through some of your correspondents, inform me upon this subject. My own opinion is, when the potatoes are placed in the hill they should be made entirely wet before hand, or after being put in the hill, by pouring water on them.

If I have missed the mode of putting up potatoes, I hope to be informed through the columns of the Southern Cultivator.

Yours, &c. J. W. MOODY.

Locust Grove, Ga., Jan. 15, 1844.

Remarks by the Editor.—We acknowledge ourself quite at a loss to account satisfactorily for the causes which produce the difference noticed by Mr. Moody, in the different sides of his heap. Nor, indeed, would we be justified in entering into a disquisition, without more data upon which to base the argument for any opinion we might entertain. We incline to the opinion, however, that either excavating or embanking for the location of a heap is not so desirable, or so apt to secure the potatoes, as placing them on the surface of the ground. This is a very important subject to all planters at the south, and with a view to have all the information possible, we last spring opened our columns to its discussion, which elicited several interesting communications from different gentlemen, containing their mode of saving potatoes, to which we beg leave to refer Mr. Moody, at pages 71, 81 and 95 of the first volume of the "Southern Cultivator," as also one or more articles on the same subject, which were copied from some of our exchange papers.

THE CULTIVATOR.—The reception from the editors, of the London "*Pictorial Times*," for December, has served to remind us that we have heretofore omitted to notice the change in the form of publication of this most excellent agricultural journal. With the new year it doned an entire new dress, and instead of the quarto form in which it has won so many laurels, it appears now in a large octavo of 32 pages, monthly. It is now, therefore, one of the handsomest (it has always been one of the ablest) agricultural papers we have the pleasure of reading.

CORN STALK SUGAR.

The following letter of Mr. Webb, which was read at the meeting of the Agricultural Society of New Castle County, Delaware, in September last, is highly interesting; the more so as it gives the result of an actual experiment in the culture of corn stalk sugar. The production of 3 tons of fodder, 500 lbs. of sugar and 50 gallons of molasses, from one acre of land, and that too by one not a regular sugar planter, versed in all the minutiæ of the business of grinding, boiling and granulating, is in the highest degree satisfactory, and, we doubt not, will encourage others to embark in making the experiment of raising sugar from corn stalks.—The enterprise is yet in its infancy, and it is reasonable to suppose that, as it advances, the spirit of improvement will simplify the whole process, so as to enable the planters generally to raise a large portion at least of the sugar consumed in their families. Nor will it stop here; for if subsequent experiments should prove that the cultivation is profitable, the sugar equal to that produced from the sugar cane, instead of being large importers of sugar, the U. States will become exporters. The subject is certainly one of importance to our planters, and we hope they will give it a fair test by patient investigation.

The American Farmer introduces the letter of Mr. Webb with the following remarks: —"We shall direct the reader's attention to to the following letter from Mr. William Webb, upon a subject of growing interest to the agricultural community. We say growing interest, because we find that the ball set in motion by Mr. Webb, is rolling onward over hill and dale throughout our land; and we do hope, and that before many years, to see the manufacture of sugar from cornstalks made a branch of the *economy* of every farm—we mean, so far at least, as the *home* consumption of the article of sugar may be concerned. Why, we would ask, should a farmer buy any thing which he can make on his own farm? If then, by devoting an acre of ground to the culture of corn, to be manufactured into sugar, he can secure a supply of sweetening for his family, why should he not do so, and thus save so much annual outlay? The *saving* of the money expended for this single item alone, would, in a life time, amount to a very handsome outfit for either a son or daughter on commencing house-keeping. And by the way, it should be the object of all farmers and planters, to keep these truths constantly in view—that true economy consists in, selling more than you buy; buying nothing which you can make at a less cost than you can purchase it; buying nothing that you have no use for, no matter how cheap it may be; saveing wherever you can do so, without resorting to meanness; and taking care of whatever you may have earned or possess. But as we did not intend to read a *homily*, but merely to introduce Mr. Webb's letter, we will quit sermonizing, and present to our readers the letter itself. Here it is:"

WILMINGTON, Sept. 13, 1843.

To Dr. W. Thomson, President of the New Castle County Agricultural Society:

Dear Sir—Since my last communication to you on the subject of manufacturing sugar from corn, a sufficient time has elapsed to bring the ideas then advanced to the test of experiment. This has been done to a considerable extent by many individuals in different parts of the country; the results (so far as known) have confirmed every reasonable expectation, and given confidence to all interested in a successful issue.

Notwithstanding the disappointments and failure necessarily attendant on all new enterprises, enough has been developed by the efforts of experimenters to show beyond a doubt that this manufacture can be profitably carried on.

If any one skeptical on this subject, will take the trouble to chew the pith of a corn stalk which has ripened without producing grain, his doubts will vanish. Indian corn and sugar cane belong to the same family of plants, and offer many points of resemblance. The saccharine matter found in their stalks, is exhausted by the process of vegetation in the formation of seed; and the sugar cane will no more yield sugar after it has perfected its seed, than will corn under the same circumstances. From analogy then, we must conclude, that the plant most productive in seed, will be most productive in sugar. This plant is Indian corn. That such a result has not yet been fully confirmed by experiment, is no proof of its incorrectness. The best mode of preventing the formation of grain upon the

plant is not yet understood. The plan hitherto practised, of taking off the young ear is as objectionable as injurious to the stalk. From some trials made the present season, it is believed that taking off the tassel will be found effectual in securing the object. Let the corn be cultivated at such distances (according to the quality of the land) as will grow the stalk about an inch in diameter.

As soon as the tassel appears sufficiently to be taken hold of with the hand, it should be pulled out; this operation does not injure the stalk in any perceptible degree.

But without anticipating improvements we will give a calculation from the results which have been actually obtained. In the first place, the fodder is at least equal in value to a crop of the best timothy hay. No green food which can be raised on a farm, is to be compared to it for increasing the milk of cows. It may be preserved for winter use to great advantage, by packing it, when partially cured, alternately with layers of any straw. If properly saved, this part of the crop will pay all expenses. We last season obtained from one acre between six and seven hundred gallons of juice. This quantity if properly manufactured, will make at least five hundred pounds of sugar and fifty gallons of molasses. The estimate then for one acre will stand thus:

	Dr.
To ploughing and harrowing	$2 50
2 bushels of seed and boiling	2 00
Cultivating	4 00
Taking off ears	5 00
Cutting up, grinding, saving fodder, &c.	17 50
Wood	5 00
	$36 00
	Cr.
By 3 tons fodder, at $12 per ton	$36 00
500 lbs. sugar, at 6 cents	30 00
50 gals. molasses at 30 cents	15 00
Stalks after grinding	4 00
Ears taken off	1 00
	86 00
	36 00
Balance	$50 00

Our operations, the present season, are not yet sufficiently matured to furnish any further observations.

I am respectfully yours,
WILLIAM WEBB.

NORTH CAROLINA TEA.—A communication appeared in the Richmond Enquirer a short time since, on the culture of Tea, from the China seed, in Grenville county, N. C. It was supposed by many at the time to be a hoax, as the writer, a Mr. Newbell Puckett, was not generally known in the county—but a correspondent of the Raleigh Register thus explains matter:

Some business called me to that neighborhood this week, where I met with Mr. Edward Lewis, who informed me that Mr. Puckett was his mother's overseer; and that the letter to the editor of the Richmond Enquirer was no hoax. The fact that Mr. P. came to this state last winter, and has occupied an humble, but respectable station in life, satisfactorily accounts for the limited acquaintance which the neighborhood has with him. At the request of Mr. Lewis, Mr. Robert Eaton and myself visited his mother, the lady in whose service Mr. Puckett is now employed. He states that an acquaintance of his found some seed in a paper of tea, and planted them in a flower box. They vegetated, and the seed of the plant matured in the fall; and were sown the following spring, and cultivated with success. Mr. P. brought some of these seeds with him to this State, and divided them with his employer, Mrs. Lewis. From these, which they sowed last spring, they raised about half a gallon of seed. Mrs. Lewis favored us with some of the tea, prepared in the usual way, and, in flavor, it very much resembles the foreign tea. By comparing the pods, leaves and stalks, with cuts or plates of the Chinese tea-plants, found in encyclopedias and gazetteers, you may perceive a striking similarity. If this should prove to be the genuine article, and can be successfully cultivated in the United States, it may not only keep in circulation among us thousands of dollars, which would otherwise be transported to a foreign land, but will place a pleasant and nutrative beverage in the hands of every cottager.

Yours, most respectfully,
L. K. WILLIE.

Oxford, Jan. 10, 1844.

PLANTERS' CLUB OF HANCOCK.

The Annual Fair of the Planters' Club of Hancock, will take place at Sparta, on Friday and Saturday, the 1st and 2d of November next, when the following premiums and honors will be awarded:

For the best acre of upland corn, a silver cup, value $10 00
second best 5 00
third " 3 00
fourth and fifth, do. Honors.
best acre of low ground corn 5 00
second do do 3 00
third do do 2 00
fourth and fifth do. Honors.
best acre of wheat, on upland, a silver cup, value 10 00
second best, a premium of 5 00
third do do 3 00
fourth and fifth, Honors.
best acre of Cotton, on upland, a silver cup, value 10 00
second best, a premium of 5 00
third do do 3 00
fourth and fifth, Honors.
best acre of Oats, a premium of 3 00
second best do 2 00
third, fourth and fifth, Honors.
best acre of Sweet Potatoes 3 00
second best 2 00
third, fourth and fifth, Honors.
best acre of Turneps 3 00
second best 2 00
third, fourth and fifth, Honors.

By a rule of the Club, competitors for premiums on crops, will be required to give the modus operandi of culture, the quantity and quality of manure applied, and evidence that the land reported on contained a full acre, and crop accurately measured.

For the best Jack, a premium of $5 00
second best 3 00
best Georgia raised Mule 3 00
second best 2 00
best Mule Colt 3 00
second best 2 00
best Stallion of 4 years or upward, ... 5 00
second best 3 00
third, fourth and fifth best, Honors.
best 3 year old Colt or Filly 3 00
second best 2 00
third, fourth and fifth best, Honors.
best 2 year old Colt or Filly 2 00
second best 1 00
third, fourth and fifth best, Honors.
best brood Mare, with or without a colt 5 00
second best 2 00
third, fourth and fifth best, Honors.
best Bull 3 00
second best 2 00
third, fourth and fifth best, Honors.
best 2 year old Bull 2 00
second best 1 00
third, fourth and fifth best, Honors.
Cow producing the largest quantity of milk, without regard to blood 5 00
second best 3 00
third best 1 00
fourth and fifth best, Honors.
best Milch Cow 3 00
second best 2 00
third, fourth and fifth best, Honors.
best 2 year old Heifer 2 00
second best 1 00
third, fourth and fifth best, Honors.
best Ram 2 00
second best 1 00
third, fourth and fifth best, Honors.
best Ewe 2 00
second best 1 00
third, fourth and fifth best, Honors.
best Boar 3 00
second best 2 00
third, fourth and fifth best, Honors.
best Sow 3 00
second best 2 00
third, fourth and fifth best, Honors.
heaviest fat Hog, from 1 to 2 years old, in proportion to age 2 00
second best 1 00
third, fourth and fifth best, Honors.
heaviest Pig, agreeably to age, from 6 to 12 months old 2 00
second best 1 00
third, fourth and fifth best, Honors.
best piece of 8 yards Homespun, for gentlemen's wear 3 00
second best 2 00
third, fourth and fifth best, Honors.
best Counterpane 3 00
second best 2 00
third, fourth and fifth best, Honors.
best piece of 10 y'ds Domestic Silk ... 5 00
second best 3 00
third, fourth and fifth best, Honors.
best article of Negro Clothing 2 00
second best 1 00
third, fourth and fifth best, Honors.
best article of Negro Blanketing, of cotton or wool 2 00
second best 1 00
third, fourth and fifth best, Honors.

The Club has set apart ten dollars, to be awarded by their committees to articles manufactured by ladies, not enumerated in their premium list, such as Capes, Collars, Caps, Pockets, Baskets, or any fancy article made by a lady.
TUTTLE H. AUDAS, Sec'y.

Sparta, January 23, 144.

CURE FOR BURNS.—Burns or scalds may be relieved, and speedily cured, by an application of *ink* and raw cotton, to take out the fire, and a salve of lard and Jamestown weed, to heal the wound. The salve is made by stewing the leaves or seeds of the weed in lard, and straining through any thin cloth. This is an excellent article for sores of any kind. Fresh cuts are soon healed by its use, and if you have a horse with galls or sore back this is a superior remedy. Every family would act wisely to always have the salve in readiness.

ANOTHER.—Another good remedy for burns is a preparation, one part of lard, one part of rosin, and a half part of turpentine, simmered together till all are completelg melted. The burns, with an application, should be washed daily and dressed with fresh ointment.—*Tennessee Agriculturist.*

LOCK-JAW IN A HORSE.—Loraine gives an account of successful treatment for this disease. A mare, from severe treatment, had a violent attack of the lock-jaw, and after it had continued nearly a day, the animal was incapable of rising, and seemed to be in the agonies of death. Dr. Dewes was consulted, who having been informed by Dr. Ruse that he had cured a horse of the lock-jaw by dashing cold water over him, recommended this treatment. Thirty or forty buckets of water were dashed over her head and body with despatch. But little effect was produced, and in about two hours the bathing was repeated, and then the clenching of the jaws was a little relaxed. A third was tried and she bit the grass around her, though unable to swallow it. A fourth enabled her to eat, and the next day she was well, and for three years, the time the account was given, she had been as healthy and active as ever.—*Far. Gazette.*

EFFECTS OF DEEPENING THE SOIL.—The Liverpool Times gives the following fact, illustrating the beneficial effects of loosening the soil to a considerable depth:

"On Saturday last, there were exhibited in the Exchange News Room, two enormous specimens of the red beet, or mangel wurtzel, grown by Mr. Robert Neilson, in a field on his farm at Halewood. Each of them weighed upwards of 20 pounds. They were not merely curiosities in themselves, but remarkable proofs of the effects which may be produced on vegetation by the deepening of the soil, for the ground which produced these gigantic roots, would certainly have produced double the quantity of potatoes, or of turneps, or of ordinary sized beets, usually grown on an equal extent of land. They show that by deepening the soil, an amount of produce may be got from it much greater than any one has yet thought it possible to raise."

GREEN AND DRY WOOD.—A cord of wood whilst green, is said to contain 1443 pounds of water, which would make one hogshead and two barrels Let every farmer who hauls wood to market, remember that when he transports it green, he is carrying that weight and quantity of water on his load, which if he had suffered his wood to remain after it was cut till it was suitably seasoned he might save from the burden of his oxen or horses, or pile upon the top of it three-fourths of a cord of seasoned pine, and yet have no heavier load than the green cord alone weighed.—*Maine Cultivator.*

COTTON IN INDIA.—The following item of news, received by the late arrivals from England, will be interesting to some of our readers; The report of the Bombay Chamber of Commerce, contained in the Indian newspapers, shows that the experiments in growing cotton have been, on the whole, successful. A specimen of Nurma cotton was pronounced to be a very fine, soft, strong, long, and clear-colored staple, which would complete with the very best American short sample cotton, could it be produced in sufficient quantity.

HABITS OF SPIDERS.—The following curious fact is given on the authority of Mr. Spence:—Having placed a large full grown spider on a cane planted upright in the midst of a stream of water, he saw it descend the cane several times and remount when it had reached the surface of the water. Suddenly he altogether lost sight of it, but a few moments afterwards, to his astonishment, perceived it quietly making its way on the other side of the stream. The spider having spun two threads along the cane, had cut one of them, which, carried by the wind, had become attached to some object on the bank, and so served the spider as a bridge across the water. It is supposed that spiders, when adult, always use similar means to cross water.

LOVE OF HOME.—The Irish are often ridiculed, or contemned, for vaunting the comfortable homes they have left behind them. "The Almighty knows," they say, "what we've come here for, we were a dale better off at home!.' This is false in word, but true in feeling. Their earnest affections take possession of their memories, and efface all but that which made the happiness of their birth-place, and childhood's home. There, in perpetual freshness, are the joys of youth; the associations of song and story are there; there, in golden light, all the bright passages of life—its pleasant acquaintanceships, and sparkling incidents. And there, those ministers of suffering, trial, superstition, even death itself, have their root of sorrow plucked out, and become ministering angels, messengers from another world! Who ever looked back upon home, through the vista of time, or the wide spaces of distance, and saw any thing but light and beauty there? Surely, then, the poor Irish may be pardoned the hallucinations of their filial love.

SCALDED MILK FOR BUTTER.—In the Boston Plowman, we notice that Mr. Johnson, of Framingham, scalds his milk during the winter season after drawing it from the cow, and then sets it away in the usual manner. The butter made from the cream is as yellow, sweet, and solid as it made in June. The same things is done by all good butter-makers in this vicinity, with the same effects as detailedby Mr. Johnson.—*American Agriculturist.*

As it is characteristic of great wits to say much in few words, so small wits seem to have the gift of speaking much and saying nothing.

AUGUSTA MARKET.

TUESDAY P. M., February 6.

Cotton—Since our report of the 24th ultimo, which left the market in a very inactive and depressed state, accounts from Liverpool to the 4th January, were received by the steamer at Boston, which show an active market and a slight advance on former prices The effect of this news upon our market was instantaneous, and the rates advanced to the highest point of the season, at which the market continues very firm. We quote 8½ to 9¼ cents as extremes—principal sales 9 to 9¼ cents. Ten cents has been refused for a crop lot in square bags, gined by the Carver gin.

Exchange—Checks on New York, Savannah and Charleston are abundant at par. Central Bank bills 3 @ 4 ℔ cent discount. Georgia 6 ℔ cent Bonds are dull.

GARDEN AND FIELD SEED.

A GENERAL assortment of fresh and genuine GARDEN and FIELD SEED, among which are the following:

Red and White Clover,
Blue and Green Grass,
Rye and Orchard do.,
Timothy and Herds do.,
Millet and Lucerne do.,
Seed Corn of every valuable variety,
Seed Wheat,
Buckwheat and Potato Oats,

Kept constantly on hand by the subscriber, all of which are offered for sale at very moderate prices. All orders, by mail or otherwise, executed with neatness and despatch.

SOUTHERN CULTIVATOR.

VOL. II. AUGUSTA, GA., FEBRUARY 21, 1844. No. 4.

From the Spartan.

Substance of a Speech delivered by Col. E. C. LEITNER, *before the Spartanburg Agricultural Society, at their last Anniversary.*

Gentlemen—In discharging the duty which, by your request, I am now about to undertake, my acknowledgment of inadequacy from the almost entire want of experience in the modus operandi of agriculture, will serve as a sufficient apology for confining my remarks to the great utility of Agricultural Societies. "In union is strength," and be the contemplated accomplishment what it may, union of strength ensures success.

"The greater the force the greater the impression," is a remark as extensive in its applicability as is physical nature itself. Nor does the effect of force exhibit itself in that which is physical alone, but is seen in intellectual efforts also.

Knowledge is not found to be self-existent, but is the result of the exercise of talent; and its increase is always in proportion to the amount of talent exercised, whether it be that of one man, or the concentrated talents of many men. In most instances, however, it is acknowledged, that where theory must be endorsed by practice before confidence will enlist, much more can be effected by the many in a given time, than by a single individual, though he were to labor for a period equal to the aggregate time employed by the many.

The agricultural art is purely practical from its very nature; therefore, the great necessity of concentrating the talents of many, in order to procure its rapid development. For, by experiments in agriculture, a knowledge of the art is to be obtained, which will always be in proportion to the number of well directed experiments. But of what avail would be the strife after knowledge in this or any other practical subject, unless it be communicated when obtained? The objectors to voluntrary associations, would perhaps say that recourse to the press would answer every purpose. To this we would assent, if every one would take every paper devoted to the agricultural interest. But who is it that does? One man brings to his aid the knowledge he derives from one paper, while his neighbor uses another, which, as far as it goes, is well enough; but would it not be much better, and attended with more immediate benefit, if, after a community of men have been thus laudably engaged, each in his own way, to improve his knowledge in "the great parent art," they would assemble at least once a year, and freely communicate upon the subjects, and success of the experiments by each made? If communities of men would thus act together, the knowledge which now exists, but which is almost imperceptible by its effects, owing to its partial dissemination, or probably owing more to the distinctive variety of subjects composing the "one art," which each man has informed himself, but which is not commonly appropriated, would be concentrated as to its force and wider spread in its application, so that each man could appropriate to his benefit the aggregate knowledge of the whole community, as easily as he now does that which he may have obtained by his isolated exertions.

But how are men to avail themselves of the knowledge acquired by each other, with greater facility than by social intercourse, than by mutually interchanging views, declaring the result and explaining the mode of operations by which that result was obtained? All will admit that it is the most expeditious and effective means.—From social intercourse, advantages of a much higher order may be gained than new books can afford on the subject of agriculture. Suppose the inquiry to be—"How shall we realize the greatest product of corn from a given quantum of land and labor?" To obtain this information, ten farmers from the number of your society are selected, to make experiments; each one adopts the mode of planting and cultivating, which, in his opinion, will succeed best, and at the meeting of the Society, (and in the presence of the whole Society,) each one of the ten appointed for the purpose, exhibits the result of his labor, and explains the plan pursued to obtain it. In this way, each member of the association obtains, in one year, an amount of practical information, which would otherwise have cost him the labor of ten years.

To the growers of stock, too, much good will result from Agricultural Societies. A premium offered for the finest domestic animal of whatsoever kind, will induce farmers to turn their attention to the improvement of their stock, not because the premium itself is an inducement, but because by such tribute of reward, an honorable emulation is excited to excel at exhibitions, more from the honor consequent upon the reward than the reward itself.

Apart from the above consideration, an agricultural society is of incalculable benefit to stock raisers, because these premiums will enhance their value. The fact that your cow, or horse, or hog, had taken the premium as being the finest animal of the kind exhibited at a show of animals, would give to a purchaser of fine stock a higher estimate of its value than any commendation of yours could inspire.

In confirmation of these views, I might instance those sections of our State in which Agricultural Societies have been organised. With Fairfield District especially, I claim to establish my views. Examine for yourself the papers of the day, and frequent advertisements of "fine stock for sale," may be found from that District, and it not unfrequently happened that a cow and calf has sold here for *one hundred and fifty dollars*. And thousands of acres of land which were, ten years ago, thrown away and given up, to be disfigured by gullies, as worn out and valueless, are now in a high state of cultivation, and yielding to their owners far heavier crops than they were capable of when first cleared. And the very lands which six years ago would not have commanded, upon an average, five dollars per acre, could not now be purchased for ten dollars per acre. All of which, as every one acquainted with that District will say, is mainly attributable to the influence of the Monticello Planters' Society. With confidence, therefore, I recommend the formation of an Agricultural Society in our District; for just as sure as like causes produce like effects, just so sure will such a Society benefit our district.

We may promise ourselves, as farmers, other benefits, which we think Agricultural Societies will promote. No one will deny but that Agriculture has heretofore been esteemed as one among the humble pursuits of life—as not possessing in itself material for investigation beyond the capacity of the humblest intellect. It has never been permitted to be ranked among and to be called a science, but has ever been esteemed as a mere art, to be learned from imitation, and requiring neither taste nor talent to enable its initiated to become *par excellence* with the most perfect of their predecessors. At the same time all will admit that agriculture is the source and foundation of every comfort of the human family, and of the wealth, power and glory of a nation; that although the seas and oceans bear our vessels to every nation on the globe, yet agriculture *alone* unfurls their sails and gives their freight; that notwithstanding science, by its magic power, has thrown the wide world into a mere neighborhood by the influence of steam, yet were it not for agriculture, distance would again be what it was, and the now artificial neighborhood would spread out again into a world. Whilst this is admitted, it seems no age of the world has given to it an attention worthy of its position, or which would warrant a conclusion that they knew its importance. The prevailing ignorance upon the subject of our remarks is farther manifest, from the singular fact, that agriculture has undergone less change in its manner of pursuit, than any other of the ancient arts. Mechanics are now affording to the human family comforts and conveniences of which the people of the last century never dreamed—and the same might be said of the learned professions—but where is agriculture? It is now where it was at a period so far back that history cannot inform us who is entitled to the honor of having done for the art what has been done for it. If we knew who invented the plow, and taught the horse and ox to become subservient to the uses of man, we would be compelled to revere him as the greatest benefactor of the human family, and as alone entitled to the singular honor of having possessed a skill in his profession, a superiority over which no individual of any subsequent age has been able to claim. And why is it so? Is it because it wants importance? or is it because its importance has never been appreciated. To the latter we must attribute its neglect. Parents never educate their children with a view to qualify them for the pursuit of a planter. Yet, if they design their children for any of the learned professions, they consider an education indispensable—an education favorable to the particular profession. But the world practically carrying out the idea that "any fool can be an agriculturist," none are educated for that purpose. Hence we may account for the existence of so many worn out and desolate farms—the frequent occurrences of those distresses consequent upon emigration. It is not from choice that men leave the home of their youth, the graves of their parents and children, of their friendly associates in life, the altars by which they worshipped, and around which thousands of friendly associations cluster; it is from necessity. Ask these, when you witness their distress upon the eve of emigration, why they go, and they will answer, "I can no longer make a support here." It is the tyranny of ignorance in the art of agriculture that creates the necessity. This state of things can only be remedied by awakening up an interest in the cause, which the efforts of Agricultural Societies can effect. Then will learning lend her

aid in developing the "riches of the art;" then will our country be able to claim her citizens as her wealth, and the great pride and boast of man consist in exhibitions of devotion to his country's good, by his attainments in agricultural knowledge.

ADDRESS OF THE HON. CHAS. DAYAN, BEFORE THE LEWIS CO. N. Y. AGRICULTURAL SOCIETY.

Extracts from the Address.—From the foregoing remarks, gentlemen, you will discover the importance of your position, and the importance of your occupation. It is undeniably true that your occupation is as honorable as any on earth, claiming the greatest antiquity, and in fact being the only one supplying the absolute wants and necessities of life, and as such must claim a pre-eminent usefulness. In a political point of view, you are emphatically the "bone and muscle" of the nation; you hold the power and the reins of this government in your hands. It is among the agricultural part of community that you find that integrity of purpose and purity of morals which form the moral integrity of a nation. You hold this power, it is true, but beware how you use it. All power in the hands of man is liable to abuse.—It is a characteristic of our nature to be inflated with power and to transcend our powers and duties for no other reason than that we have them; from you this abuse of power is hardly to be expected, so long as you sustain that moral and political integrity which have heretofore characterised your profession. You must always remember that ours is a government of laws based upon equality—equal rights and equal privileges are the legitimate inheritance of every American freeman; never use the power to degrade, impoverish or enslave your fellow man—for remember the language of St. Pierre, "That while we are riveting one end of the chain around the ancle of the slave, Divine Justice is riveting the other end round the neck of the tyrant."

No class of community has done more for society than you have The farmer has in all ages of the world been the pioneer to christianity and civilization—you have cut through and gladdened the way for the gospel ministry, and prepared them to carry the glad tidings of the gospel to the remotest part of the nation. In a word, you have been instrumental in civilizing and christianizing a world—for who can deny but what christianity and civilization have followed in close proximity the axe and the arm of the husbandman.

You have always nourished and sustained all other branches of industry—they have been solely and entirely dependent upon you, and are so now and always must be. Agriculture, Commerce, and Manufactures, have been denominated twin sisters, mutually dependent upon each other. But strike out of existence Agriculture and Commerce, and manufactures must, of necessity, perish. Strike out the other two, and agriculture, of necessity, must survive. Strike out agriculture, and man can only live as long as he can sustain himself on the spontaneous productions of the earth. Hence you see that you are not only the lords of creation, but the lords of the soil; and as such, you should, by all commendable means, strive to elevate yourselves to the dignity of your profession. You are styled the great producers of the nation—your productions are consumed by all the nations of the earth. Your national flag flutters in every breeze, and every port and harbor is whitened by your canvass. You may say these are high sounding words without meaning—examine for yourselves and you will find it true to the letter. Hence the dignity of your calling. You live in an age of improvement, and the field before you is wide, and it must be occupied by you, your children, and your children's children—and fear not, my friends, that your profession will be overstocked.

* * * * * * * *

I have already detained you long, and will close, by making a few remarks to the fathers and mothers engaged in agriculture. The father should duly appreciate the increased intelligence of his day, and consequently see the necessity of educating his sons. Scientific works on agriculture should be put into their hands and their attention called to their necessity. You should also teach them in the most concise plan of practical husbandry: when you try experiments, test them in the presence of your sons, explain to them the principles of your tests, and lead them to believe that demonstration is the best mode of instruction—teach them to reason from cause to effect, and to watch every practical result, and above all, teach them industry.—Teach them the old proverb, "a young man idle, an old man needy." That business is the salt of life, idleness its canker. Teach them that God, in the fulness of his wisdom, has ordained that the necessity of labor should be the enjoyment of man, and that it is honorable—teach them that labor gives strength and vigor to the moral as well as the physical faculties—that it gives food to the mind and strength to the body.

If you have hired men, never reflect upon their condition of life, but on all occasions give them to understand that you will estimate them by their moral worth.

Never taunt them for their poverty, unless it is the result of idleness and crime: in a few words, do all you can to sweeten their toil and condition of life: this will give them a cheerful heart, and a cheerful heart will give them a willing hand. In all your deal with them, maintain a scrupulous integrity, and for the time being as a father, aid and direct them by good and honest counsel.

To agricultural mothers I would say, educate your daughters in all the domestic relations of life. Teach them to know that honest industry is honor; idleness, dishonor; that industry is health and wealth; idleness, misery and want. These are obligations you owe your daughters, if you wish to prepare them for future usefulness in society. Teach them to despise the empty scoff of that female who is too good in her own estimation to work, devoting her time to spinning street yarn, and who, like Solomon's lilly, toils not, neither does she spin, and whose little hands are too delicate to knead a biscuit. Mothers, depend upon it, your daughters, in the estimation of all intelligent people, rightly educated, are held in higher estimation than those who sneer at honest industry; teach them never to feel themselves degraded by domestic duties. Teach them to stand to their post when they see a person approaching the door, and not run for fear of being caught at work. Teach them that every sensible man will pity a girl who runs to avoid the imputation of labor, and will despise her extravagance, if she should be caught at the wash tub in a silk dress. If you have female domestics, instead of treating them with neglect and indifference, be to them for the time being, a friend and mother—treat them with kindness and respect, and if occasion should require, throw the mantle of charity over them. Teach them that their toil is not servile but meritorious—do this and you will seldom want help.

From the New Genesee Farmer.

USE AND PREPARATION OF THE FOOD OF VEGETABLES.

To understand the process of nature by which certain elements of earth, air and water are transformed into living plants, and the best method of preparing these elements so as to produce the largest crops at the least expense, are objects worthy of the careful and profound study of every cultivator of the soil.

If we take 100 pounds of ripe hay, oats, wheat or corn, including the roots, stems and seed, and burn them carefully in the open air, we shall have only about 3 per cent of alkaline earths left, most of which can be dissolved in water. If we burn a pound of candles, or a pound of oil, whether animal or vegetable, the whole of these substances (which are truly "the fat of the land") will be transformed into invisible air and vapor. The atmosphere and water are nature's great storehouse for preserving an exhaustless supply of vegetable food. By *respiration*, *fermentation* and *rotting*, all organic structures are transformed into gases and soluble salts. It is from the lime dissolved in the ocean that the oyster elaborates its shell, and the coral insect rears its massive mountains of coral rock. It is mainly from the phosphate of lime held in solution in its mother's milk, taken from her food, that the sucking calf elaborates its solid bones. Without lime to be dissolved in her gastic juices, and taken into her circulating blood, the hen can make no solid shell to her egg The unnursed infants in the great cities of London and Paris, brought up without milk, and fed on arrow-root and other food that contains little or no lime, have soft, cartilaginous, rickety bones, simply because neither animals nor plants can make *something* from *nothing*.

As a general rule it is strictly true, and moreover it is a truth of great practical importance, that a feeble, diseased stem in wheat, liable to rust, &c., and a shrunken berry, are owing to some removable defect in the food of the plant. So different are the essential elements of the seed of this plant from those of its straw, that it is practicable to raise wheat that will yield twice as much grain in weight as there is weight of straw, taking it from the root. That it is also practicable to grow wheat which will give five times as much straw as grain, most farmers know by sad experience.

On page 254 of Transactions of the New York State Agricultural Society, 1842, Gen. Harmon, of Wheatland, states, that "In 1803, Pettin Sheffer, Esq., of this town, harvested 40 acres of wheat grown on the Genesee flats, that produced 62½ bushels per acre." What elements did nature provide, and where did she get them, for the growth of such a crop? Manifestly they came from the mineral and vegetable matter washed down from the highlands above. These elements are just as abundant now as they were at the close of the creation. Having found out, within the last 40 years, since Mr. Sheffer harvested his famous crop, what these vegetable elements are, and how to combine them under more favorable arrangements for the production of *cultivated* plants than nature has anywhere done, men of science have greatly exceeded the above large product. From nature's crab-apple, that weighs less than an ounce, science has at last grown fruit weighing twenty times as much, or 2000 per cent. more than the original!

By the use of charcoal and lime, a Mr. Pell, of Goshen, in this State, has harvested this season at the rate of 78 bushels 24 quarts of wheat per acre. The ground was accurately measured by a surveyor's chain, and the grain a sealed half-bushel, and the statements are all sworn to by two reputable men. I notice this triumph of science with the more pleasure, from the fact that I have long and zealously urged the use of these abundant elements upon the attention of the readers of the papers for which I have written.

It is more than twenty years since I first began to use pulverized charcoal to absorb the gases given off by decomposing vegetable and animal matter, urine, and the like, to be applied to garden and field crops. Its value in correcting the taint in meat, and purifying rain-water in filtering cisterns, led me to believe that it would be just the thing to absorb the food of plants from the atmosphere, into which so much passes, and hold it about their roots in a condition that neither dew, rain, snow, frost, nor the heat of the sun, would injure it or take it away. To labor hard to save and draw out manure on to one's fields, and then lose 60 or 80 per cent of this vegetable food by its solution in water, and washing away to form something like the Genesee flats in the bottom of Lake Erie, I never regarded as very good economy—which, by the way, is the soul of good husbandry.

A pint of human urine contains ammonia enough to make, with the other necessary elements, 60 pounds of good wheat. Charcoal

will absorb this liquid, and render it quite inoffensive to the olfactories of the nose. The direct application of urine to the soil, after the German practice, is bad economy, unless the soil contain a large portion of humus, or vegetable mold, for its tenacious retention. It is a better plan to have a reservoir filled with pounded charcoal under the stable floor, or near to the stable, into which the liquid excretions of all animals should be conducted like cider from the press. When nearly or quite saturated with urine, this coal will be manure of extraordinary power and durability—for nothing in the soil, but the roots of growing plants, will be likely to extract a particle of this vegetable food.

After wheat, corn, or grass has taken up all this nourishment, the coal (unlike lime, which has parted with its carbonic acid in the same way) is insoluble in water, and remains, as in a filtering cistern, to absorb and hold, for the benefit of the growing plant, more vegetable food from every rain that falls to the earth. For be it remembered, that dew, rain and snow—the poor man's manure, bring back to the earth all the gaseous elements given off by all the fires, respiration, and other decomposition of solid and liquid matter.

For the same reason, coal should be largely used in the formation of compost heaps. And where the farmer has straw which he can use to make beds for his horses and cattle in the stable, this, with a quantity of coal pounded with a flail, can be spread upon the stable floor, to absorb all liquid excretions. All these excrementious substances should be kept under shelter. Wood ashes, lime and muck, or vegetable mold, are valuable ingredients in all compost heaps. The coal stratum should be placed between the lime and the manure, and the whole should be covered with turf or more coal.

The analysis of soils abounding in fragments of limestone rocks shows a marked deficiency of this important element in their composition. The reason of this perhaps unexpected deficiency I will now explain:

Disintegrated limestone is decomposed by the vital action of plants, and its carbonic acid is taken up by their roots. It will then combine with more of this gas which abounds in the air and soil, and will again give it out to growing vegetables. It is in this way that plaster (sulphate of lime) after it has parted with its oil of vitriol, often produces such wonderful effects, although the amount applied is less than one forty thousandth part of the soil from which plants draw their nourishment. The action of the sulphuric acid, as I understand the matter, I will not stop to elucidate. But I wish to fix public attention upon the circumstance, that when lime in the soil has parted with its acid, whether sulphuric or carbonic, and especially the latter, it is soluble in water, and hence very liable to be washed out of the soil by rains, &c. All water that has passed through a soil possessing sufficient lime to be good wheat land, is *hard*, or holds lime in solution of which it has robbed the soil. The same is true, in a less degree, with regard to leaching of the soil, and its loss of allumina, potash and soda. The cultivation of the earth, without allowing any vegetables to grow upon it, would exhaust its fertility very rapidly.

The remedy for this is, to cultivate less land in grain crops, and cultivate it far better; to remove all excess of water by draining; to plow deep, and turn up to the sun virgin earth from below, and apply thereon manure, coal, lime, ashes and salt. Instead of applying large quantities of quick lime at distant periods, it is far better to apply a less quantity and often, to make up for the loss that occurs from its being dissolved in water, and carried with it into rivers and the ocean.

Leached ashes are valuable when applied to grass lands; and are far from being worthless on wheat, rye, oats and barley—all of which need their silicate of potash, to give them a good, firm stem. Grass and wheat know as well how to convey the apparently insoluble elements in leached ashes up into their organic structure, as did the trees from which these ashes were obtained. D. L.

Buffalo, Dec. 17, 1843.

GARDENING.

The season being at hand for gardening, we consider it our privilege as journalists to suggest a few things in reference to the importance of the science as well as instruction on the first and most important operations.

The history of gardening is most interesting in all its details, and for information on this subject we commend to the reader's attention Loudon's Encyclopedia, as containing more valuable information than all other works we have examined. In point of profit, no labor gives a better reward than that performed in the garden. Near large cities, extensive and industrious communities make handsome supports from the sale of vegetables and fruits.

No family, scarcely, sufficiently appreciates the every day comforts, to say nothing of the luxuries, of the garden. Vegetables and fruits may give at least half a support to a family, and when it is considered they constitute the most healthful and agreeable diet, they become much more valuable. It should not be forgotten that the science of gardening is an intellectual employment of the higher order. Botany, geology, chemistry, vegetable physiology and entimology are intimately connected with its practices.

Again, none but those who cultivate the garden can estimate the pleasure accruing to those who spend a portion of their time in its operations There is not a seed, sprout, leaf, bud, flower, or particle of fruit that does not afford pleasure in an eminent degree. No marvel, indeed, our Heavenly Father should have selected a garden for the residence of the first happy pair, and no wonder the most scientific of both sexes, throughout the civilized world, are charmed and delighted with the garden.—We will, however, not enlarge on this part of the subject.

The operations of the garden shall next have our attention.

1. The matter first to be studied is the location and character of the soil. For early vegetables it is preferable to have a southern exposure. The morning sun brings forward plants much faster than the evening rays, and therefore, when practicable, the land should incline to the southeast. For late roots, gooseberries and currants, a northern protection from the scorching rays of a mid-summer sun becomes necessary. The soil is of much moment.—Frequently there is a superabundance of clay. When this is the case, no application is better than sand. Pulverized charcoal is excellent on clay, (I have tried it.) When sand superabounds, clay may be put on advantageously.—But for an unproductive soil, well rotted stable manure may be indispensable. Fresh mold from the woods has advantages over all other applications. It is freer from insects, and injurious seeds of weeds and grass, than stable manure, and has no tendency to fire the plants.

The most important point in a country garden, is to obtain a sufficient quantity of manure. In towns it is not so, and not unfrequently there is so much put upon gardens that neither vegetables or flowers are good. There is little fear though to be anticipated on this score in our country gardens. To get enough vegetable mold is the important matter. This will correct most evils of a soil.

2. No time should be lost in spading the ground, and having it made ready for sowing. In our judgment, the more the soil is exposed to the frosts the easier it will be of cultivation, and the more abundant the crops. We think it no economy to plough a garden. Potatoes, beets, carrots, &c., may be cultivated as field crops, and then ploughing is preferable; but in the garden the spade, hoe, fork and rake, should be the chief implements. Land can be put in better state by one spading, than four ploughings, and when the plough is the reliance, we generally find it inconvenient to use it after the seed are sown, and the consequence is, too often, the weeds take entire possession. But whatever instruments are used, the soil should be thoroughly pulverized to a considerable depth, and always kept friable and free from weeds, which drink up the soul of the earth.

3. The first preparations should be for early peas, radishes, lettuce and potatoes. The soil for peas should not be very rich in stable manure. One-third of sand and two-thirds of vegetable mold answer admirably. We call attention also to another item in the cultivation of peas, which is not generally regarded. Commonly, the drill is too deep and narrow for early peas. Raise the soil about four inches, and open a trench at least six inches broad, and scatter the seeds plentifully over the whole. By this mode, the sun will have the greater effect; the rows will be broader; the stocks will mutually assist each other; fewer sticks will be required for support; and the crop will be three or four times as great as in the ordinary plan. Early peas may be protected by planks or broad rails during freezes, and the sun should exert all his influence in the heat of the day.

For radishes and lettuce, when not protected by glass, open beds should be made. Their construction is simple and cheap. Mark off a bed the size wanted, take out from six to ten inches of the surface, and fill it two-thirds full of unrotted stable manure, old tan, or fresh leaves. Some eight or ten days afterwards, put on about six inches of good garden mold, rake it to a level, and the sowing may commence the first open day. If cheap frames were put around such beds, and they could be covered with plank in bad weather, the plants would come forward a little sooner.

Cabbage seed might be sown in the same manner for early crops. But in all these operations, judgment, and many circumstances dependant upon the season, must of necessity have a contrary influence.

Nashville Agriculturist.

EXPLANATION OF TERMS.

(Continued from page 191, Vol. 1)

24. *Rotation of Crops*—is a course of different crops, in succession, on the same piece of ground, for a certain number of years, after which the course is renewed and goes round again in the same order.

There is a difference between a *course of crops* and a *rotation of crops*. Thus, if a piece of ground in sward be broken up and planted with Indian corn the first year; the second year with potatoes; the third year sowed with oats and grass seed; and mowed the fourth, fifth and sixth years—this makes a course of crops.—If, then, the seventh year, it be again broken up, planted as before, and the same course of cropping pursued, it becomes a *rotation of crops*.

25. *Soiling*—is the feeding of cattle, either in the barn or yard, through the summer, with new mown grass or roots.

26. *Live Hedge*—is a fence formed of living plants, usually the white thorn, planted closely in rows, which, being trimmed annually and kept clear of weeds, in a few years grow into a living, permanent fence, capable of stopping effectually every kind of domestic animal.

Most of the common farm fences in England are of this kind.

27. *Quicks*—a name commonly given to the young plants of the white thorn used in planting hedges.

28. *Layers*—are the tender branches of trees and shrubs bent down and buried in the earth, leaving the tops out, in which situation they are fastened with hooks to prevent their rising.

The part in the earth sends out roots, after which it is separated from the parent tree, and transplanted, in the same manner as trees raised from the seed.

29. *Cuttings or Slips*—are small portions of the twigs, branches or roots of trees or plants, cut off with a knife, or slipped off with the thumb and finger, for the purpose of setting or planting

in the earth, with a view of producing new plants or trees of the same kind.

30. *Sets*—are young plants taken from the seed bed to be set or planted out.

Cabbage and various other plants are usually propagated in this way, being first sown in beds, from which the plants are taken up and set out in fields or gardens.

31. *Fallow*—signifies land in a state of rest, not being planted or sown for a season, but repeatedly ploughed and harrowed, for the purpose of clearing it of weeds, and of dividing and pulverizing the soil more perfectly.

Such is sometimes called a *naked fallow*, because the land carries no crop.

32. *A Green Fallow*—is that where the land has been rendered mellow and clean from weeds, by means of some kind of *green crop*, such as turneps, peas, potatoes, &c., cultivated by the horse-plough and hoe.

The crop so cultivated and for the above purpose, is called a *fallow crop*. In this mode of fallowing, no time is lost by the land being left idle or in an unproductive state. Fallowing is sometimes distinguished by the season of the year in which the business is either principally or wholly accomplished; hence we have summer, winter and spring fallows.

33. *Winter Fallowing*—is only breaking up the land, or ploughing it in the fall, and leaving it exposed to the action of the frosts of winter.

34. *Dibble*—is a tool of very simple construction, for making holes in the ground, at equal distances, in which certain seeds are sometimes planted.

Seeds planted in this way are said to be *dibbled in*. It is used also in transplanting. The handle of an old spade or shovel, sharpened at the lower end, may answer very well for this purpose.

35. *Tiller*—is a term used to signify the branching out of a single grain, as of rye, oats, or wheat, *into several stalks*.

Where the individual kernels of any grain throw up *many* stalks, it is said to *tiller well*. Each shoot thrown out in tillering may be removed and treated as a distinct plant. A remarkable instance of this is related in the fifty-eighth volume of Philosophical Transactions. Of some wheat sown in June, one of the plants was taken up in August and separated into 18 parts, and replanted: those plants were again taken up, and divided in the months of September and October, and planted out separately to stand the winter, which division produced sixty-seven plants. They were again taken up in March and April, and produced five hundred plants, from which grew twenty-one thousand one hundred and nine heads, yielding three pecks and three quarters of wheat, all produced from one single grain.

36. *Ley*—a term used in agriculture, to signify land in the state of sward or grass.

We frequently read of wheat being sown on a *clover ley*; by which we are to understand, land in clover, directly after mowing, being turned up, and sown with wheat on the back of the furrows.

37. *Meadow*—grass land for mowing.

In this country, the word is seldom used to signify upland mowing, but that which is low and moist, and seldom or never ploughed. In other countries, and by some writers on agriculture in this country, it is the name given to all *mowing grounds*.

38. *Effluvia*—are those small particles flowing out of any substance, which produce in us the sensation of smell.

Thus, most flowers send forth effluvia; and substances in a state of putrefaction send forth effluvia of a very different nature.

39. *Chemistry*—is the science which enables us to discover the nature and the properties of all natural bodies.

40. *A simple substance*—is one which cannot be decomposed, or which is not produced by the union of two or more substances; such as iron, sulphur, &c.

Sir Humphrey Davy, a celebrated chemist in England, reckoned forty-seven known simple substances in nature.

41. *A Compound Substance*—is one which may be decomposed; or which is produced by the union of two or more other substances of different natures.

Thus, gun-powder is a compound substance, being composed of charcoal, sulphur, and saltpetre; and these substances, or those which united together, produce a compound substance, are called its *constituent* or *component parts*.

42. *The Elements of Matter*—are the simple substances into which all surrounding objects are capable of being reduced.

All the substances about which agriculture is employed are compounds; that is, they consist of elements into which they are capable of being resolved. Of this, no farmer should be ignorant; and he ought to attain at least to so much chemistry as to know the nature, the properties, and the combinations of those elements, (the number of which is very small,) which are continually working such wonders before his eyes.

43. *Analysis*—is the resolution or separating of a compound substance into its elements, or constituent parts.

44. *Caloric*—is the name which modern chemists have given to fire; or rather, it is that extremely subtile fluid which produces in us the sensation of heat.

The sun is the grand source of caloric, it is afforded also from combustion, and in various other ways. Thus, take a small phial about half full of water, grasp it gently with one hand, and from another phial pour a little sulphuric acid, or oil of vitrol as it is sometimes called, very gradually into the water. The phial will become hot, which is in consequence of the caloric disengaged from the mixture.

This subtile matter pervades the pores of all known substances, most of which are capable of existing in *three different states*—the solid, the fluid, and the ærial form or gaseous state; and these three different states depend on the quantity of caloric which may be present in any substance, at *any one time*. The first of these, termed *the solid state*, depends on the presence of *a small quantity of caloric;* such is water in the state of ice; when the quantity of caloric or matter of heat is increased to a certain degree, the body passes into the second or *fluid* state. Such is ice or lead when melted; and by still further increasing the quantity of caloric or heat, it rises into vapor, called the *æriform* or *gaseous state*, or simply gas.

"Almost all natural bodies are susceptible of existing from the mere expansive energy of caloric in these three states; and the only difference among them is, that some require *less* and others a *greater* proportion of caloric to induce these changes. Water, which usually exists in our atmosphere as a fluid, can fluctuate by a very slight alteration of the thermometer, either into *solid* ice, or into æriform vapor. All the metals exhibit the same phenomenon. If solid, they melt by the application of fire into a fluid mass; and if that be carried to a given pitch of intensity, they fly off in fumes and assume the gaseous state. The solid earth is not exempt from the dominion of this universal law. Flint and sand, when put into the furnace, dissolve into liquid glass; and if exposed to a still more powerful heat, they are dissipated in vapor and assume new ærial forms. Let it, therefore, be remembered, as an established principle in chemistry, that when different portions of *caloric* enter into combination with bodies, they pass, according to the quantity, into the respective states of *solidity*, *fluidity*, or *æriform vapor*."

45. *Gas*—is any substance converted to vapor by the action of caloric.

In other words, it is any substance dissolved in caloric; or, it is any substance reduced to the æriform state by the action of caloric. By the *æriform state*, it must be remembered, is *meant a state similar to that of air*, which is neither *tangible* or *visible;* that is, it can neither be handled with the hands, nor seen with the eyes.

It may seem strange that the hard substances from which we receive so many knocks and bruises, should in any way be converted into such a state. Yet something of this is seen every day. A log, which it would require two men to lift, on being burnt, is all converted into gas, except a residuum of ashes so small as to be collected into a measure and carried by a child. So in the putrefaction of an animal, the solid substance left is little more than sufficient to color the ground; the rest, except some fluid parts which may have sunk into the soil, is all converted into gas.

46. *Alkalies*—are substances of an acrid, burning taste.—Their most distinguishing properties are

1st. They change the blue juices of vegetables, as of violets, or red cabbage, to green.

2d. They render oils missible with water, thus forming soap.

3d. They combine with acids, thereby forming various kinds of salts.

There are only three alkalies. 1st, Potash, or the Vegetable Alkali. 2d, Ammonia, or the Volatile Alkali. The two first are also called Fixed Alkalies; the latter, or Ammonia, is called the Volatile Alkali, because it exists as a gas, and is that substance which, on opening, a smelling bottle so effectually searches the nose and head.

JERUSALEM ARTICHOKES.—In connexion with the advertisement of Mr. J. A. CLARKE, on the last page, we desire to invite the reader's attention to the following remarks of the editors of the Tennessee Agriculturist, showing the value of this vegetable. Among our exchanges, we have seen numerous references to the Artichoke, all of which concur in recommending it as very valuable; but we deem the annexed views quite sufficient to induce the planters of Georgia and Carolina to make an experiment in raising them.

JERUSALEM ARTICHOKE—(*Heleanthus Tuberosus*)

From the fact that many enquiries have been made of late, in relation to this very remarkable and useful plant, I am disposed to speak a few things of its culture and uses. The Jerusalem Artichoke is a native of the warmest parts of America, and of course was unknown in Europe, till after the discoveries in this country by Columbus and his coadjutors. Since that time it has been cultivated to considerable extent on the continent as well as in Great Britain, but the reports of its profits have considerably varied in that, as well as this country. In the old world, some have cultivated it to afford shade to the game; others have converted the stocks and leaves into fodder for cattle, and others again, have encouraged its growth for the tubers alone. In this country, there are two important objects to be kept in mind in raising Artichokes: 1st. The improvement of land; 2dly. The use of the tubers. However, the first matter is the cultivation, and I begin with

1. *Soil.* Almost any kind of land will produce Artichokes, and it is remarkable, that they will grow in the shade, that is, under trees, or in fence corners, very well indeed. Land, however, with a tolerably good sandy mold, will give the most abundant crop. Low, wet soils, and very tenacious clay, are not so suitable.

2. *Preparation of Land.* The ground should be broken as for corn, that is to say, one good, deep ploughing, and a thorough harrowing, will answer the purpose admirably.

3. *Laying out.* Rows laid off four feet each way with a bull's tongue or shovel plough, in most soils, will be the proper distance.

4. *Quantity of Seed.* From four to five bushels will be required to the acre, and unless the long roots are broken to pieces of three or four joints, or eyes each, this quantity will not be enough.

5. *Manner of Planting.* Drop one root at

each cross of the plough, and cover from one to two or three inches with a harrow, hoe or plough.

6. *Cultivation.* So soon as the young plants appear, run round them, with a cultivator, harrow or light plough to destroy the young weeds, and loosen the earth. Keep the ground free of weeds and open to the influence of the atmosphere, till the plants are about three feet high, when they should be laid by, by the use of a cultivator; or, in the absence of a cultivator, and when the land has been ploughed, the harrow should pass both ways to leave the ground loose and the surface level. Generally, about the same cultivation given to corn will answer well for Artichokes.

7. *Digging.* This is the most troublesome job in the management of this crop; and if the hoe is the dependence, the labor will be very tedious. The better plan, is to lay off a land as for breaking up the ground, so soon as the frost has killed the under leaves of the stocks. The plough should run from 6 to 9 inches deep, and let the hands, big and little, pass directly after the plough, to pick up, that none of the roots may be covered by the next furrow.

8. *Yield.* The produce to the acre is variously estimated from 500 to 1000 bushels, and it is probable the turn out on medium land would be nearer the latter than the former.

9. *Uses.* In England and other parts of Europe, the tubers have been considered quite a delicacy for man, and without doubt they make the most beautiful pickles. But their chief importance, in this respect, is their use in feeding hogs. From the middle of October to the middle of November, the hogs may be turned on the Artichokes, and with salt always in troughs, to which they can have access, they will grow and thrive till next spring, particularly, if the ground is not too hard for rooting. I have not experimented to ascertain the quantity of hogs to the acre of good Artichokes; but from the observation of two seasons, I am of the opinion 20 head will do well on an acre for four months. As some have complained their hogs would not root after them, it may be necessary, as hogs, like men, know not much before learning, that they be taught to root after them. This is done by calling the hogs after a plough that will throw out the roots, till the grunters learn their habitation, which will require but a very short time.

10. *Improvement of Land.* As the stocks grow from ten to fifteen feet in height, and the thick, porous foliage, much of the food of the plant is received from the atmosphere, and thereby the soil is not so heavily taxed as by other crops, the ground is protected from the killing rays of the sun and the stock and leaves fall and rot very soon. These advantages, with the manure from hogs, afford the cheapest, and amongst the richest coats in my knowledge. It is my conviction, (in the absence of long experience,) that Artichokes in summer, and Hogs in winter, will enrich our poor lands cheaper and much better than upon any other plan. To be sure, a farmer cannot have all his land in Artichokes, but every one should have enough to support his hogs through the winter, and I venture those who give this crop a fair trial, will reluctantly abandon it.

11. *General Remarks.* A few farmers of my acquaintance have informed me, that they have succeeded with Corn and Artichokes together, and it is highly probable this will prove a successful mode of cultivating these two crops, but on the system of "one thing at a time," we would prefer each crop separately. Some have supposed the second year's growth on the same ground would be more valuable than the first; but this is a mistake. The plants grow so thick the second year, that not more than half a crop can be anticipated. It might answer, to plough out rows and cultivate the second year; but the practice of putting Artichoke lands in something ese the second year, is the plan I must prefer.

Amongst the arguments which might be used in favor of this crop, it should not be forgotten that there is no labor of digging, but for seed; that more troublesome weeds and grasses are completely smothered out; and last, but not least, the young plants the second year are more easily subdued than almost any weeds known. Take Artichokes all in all, I think them worthy the attention of every farmer who wishes to enrich his lands, or raise his pork with a small outlay of grain.

USE OF LIME.

We have ever been among the most zealous advocates for the use of lime; but in all our advice we have recommended *caution* to be observed in its application; and that before using it, it would be well to ascertain whether the soil is or is not deficient in it. We hear one person say that it had acted like a charm upon his land, while another will tell you, that he used it without effect upon soil of precisely the same texture where its good effects had been so manifest. The reason of this difference in effect, might be accounted for in one of these ways: 1st. That the land of the one had organic remains in it, and the other none. Hence the necessity for the analysis of soils, so that the farmer may go to work intelligently. That lime is one of the most powerful agents in the improvement of soils, there can be no doubt; but that lime alone will make a *poor* soil *rich*, we never have and never will believe. The food of plants consists of several substances, all of which is necessary to be present in the soil, before its fertility can be perfected—among these substances we hold lime to be of the very first importance—but we have long thought, that the quantity of lime to the acre, could be very materially decreased below a hundred bushels, as the only benefit to be derived to the growing vegetables from it, is from that part which is dissolved by the rains, which part is small indeed, in any one season. Why then make a *large* outlay for lime, when a *small* one would answer for all present purposes. To be sure, lime also performs a *mechanical* operation, in the change of the texture of the soil, and in so far as this effect may be desirable, a larger dose of lime may be productive of benefit. But why apply 100 bushels of lime, per acre, to an old exhausted field, where there was nothing for it to act upon, when 25 would answer better? Our views are, that before land, which may have been completely impoverished by bad culture, can be materially benefitted by the use of lime, that two or three green crops—say of buckwheat or rye—should be ploughed in. Either of these crops may be grown by applying a bushel of plaster to the acre at the time of sowing. If this course of improvement were pursued, there would not be so many croakings about the inefficacy of lime. Lime, to act efficiently, must be combined with vegetable or animal manure—with these, there can be no question of its meliorating powers, but we do most seriously question its capacity, alone, of making an infertile soil a rich one.

With regard to the quantity of lime to be applied to an acre, there is great diversity of opinion—some apply 100; some more than that, while others think 80, 60, or 50 bushels to the acre is preferable, and then there are those who think 25 bushels enough; and we confess that we are among those who think favorably of the least quantity named, unless there should either be a larger quantity of organic remains in the soil, or some two, three and four green crops be first ploughed under. We reason in this way. If 25 bushels to the acre is more lime than can be dissolved in *one rotation*, why should we deprive ourselves of the use of the money which the difference between 25 and 100 bushels would cost? If then, for present purposes, 25 bushels will answer for an acre, is not our interest to lime *four* acres with a hundred bushels, instead of putting that quantity on a single acre? The *outlay in money*, to purchase a hundred bushels of lime, deters many small farmers from using it; whereas if they could be satisfied that 25 bushels would answer as well, they would not hesitate to undertake the liming of their land; and thus would the improvement of our worn out soils go on more certainly and steadily—for let what be said, that may, the first cost of *lime*, at the rate of a hundred bushels to the acre, is a most formidable consideration, where a man has from 100 to 400 acres requiring improvement.

We will conclude by repeating what we have before said—that we believe, in all cases of improving lands much exhausted by cultivation, that for present purposes—say for a rotation of four or five years—25 bushels of lime, besides costing so much less, would be better than 100 bushels per acre—that it would be better to repeat 25 bushels per acre every four years, until 100 bushels had been applied, than to put the latter quantity on at one time.

American Farmer.

SOWING INDIAN CORN BROADCAST.

A correspondent of the Albany Cultivator, writing from Memphis, Tenn., Nov. 23d, says: "Having seen sundry interesting communications in your valuable journal, relative to the immense yield of corn sown broadcast, I am induced to give you 'my experience,' though it is the result of an experiment on a small scale. In the spring of '42, I prepared two squares in my garden, each 20 feet by 30, and sowed them with corn, about half a gallon to each square, though this is too much. When about waist high, I commenced pulling it up by the roots, and feeding it green, to a fine Durham heifer and some pigs—the latter devouring it as greedily as the former.

"I pulled up and re-sowed these squares four times during the season, and kept the animals in fine order, without anything else worth naming. This year I did the same thing; and I am satisfied nothing will produce half as much as corn thus planted or sown. Every time I stripped a square, it was forthwith highly manured, and at once spaded up and resown; and this season I had corn thigh high when frost came. I generally fed the corn as it was pulled up, but sometimes, for relish or change, it was cut up and seasoned with meal and salt."

IMPROVEMENT OF OLD FIELDS.

As there are doubtless many worn-out old fields that have, for years, produced nothing but poverty grass, we should like for some enterprising proprietors of such to make an effort to bring them back to a state of fertility; and would suggest that by sowing a bushel of plaster, per acre, on them during the present month, ploughing them up as soon as the spring crops are in, and then sowing a bushel of buckwheat to the acre, and ploughing that crop in as soon as it gets into blossom, we have no doubt that the soil would bear a crop of rye without any thing else; and that, with the addition of five bushels of lime per acre, spread evenly, a very fair crop of wheat might be grown thereon, without any addition of other manure: and we have as little doubt, that clover seed might be sown the ensuing spring, with a good prospect of a fair crop of grass, provided the plants were *plastered* as soon as the wheat crop was cut. We have seen a very good pasture of white clover produced by the application of plaster on such fields as we have described, without the aid of any other manure, by simply harrowing the ground after the plaster had been sown a few days, the precaution having been taken, in sowing the plaster, to select a moist day to do it in; and we can see no reason to doubt that, with the addition of a green crop ploughed in, a very fair one of grain might be grown. The cost of such an experiment as we have suggested, is comparatively so small, that we hope some one will test it.

American Farmer.

TURNIP FLY.—Lime slightly strewed over turnips (just up) before the dew is off the ground in the morning, most effectually and invariably preserves the crop from the fly, &c.

COTTON GROWING.

The following, upon the subject of Cotton growing, we extract from the Concordia Intelligencer, it being from the pen of our friend and correspondent, Thos. Affleck, and knowing, as we do, the interest he takes in the subject, we feel we cannot aid the cause of improvement better than by giving circulation to the statement contained in the article. We have before expressed our belief in Dr. Cloud's system, and we consider the experiment here made by Mr. Affleck, as fully carrying out the views of that gentleman.

It we could, upon our hill lands, produce even 2,000 lbs. per acre, by adopting a reasonably improving system, and by almost *any extent* of manuring, would we not be immensely benefitted? How many planters, cultivating hill lands, gather over 700 lbs. per acre? Not many. And yet, to do even this, requires incessant hard work from New Year's day until Christmas. The difference between ploughing, planting, tending, and picking over, say 300 acres, and 100 is very great, and would allow of much labor being bestowed in making and applying manure, and in extra-deep ploughing. Nor need I descant upon the comfort and advantage to the planter, of being able to plant and tend as much ground with *one half of* his hands as *the whole of them* can pick clean by Christmas—leaving him the other hall of his force for the rest of the work necessary on a farm, including, of course, under such a system, *manure-making*.

How it would astonish the farmers in my native country, to be told, that at this late day of Agricultural improvement, their brethren in every part of America, and particularly amongst the travelled and enlightened Southern planters, it required a lengthy argument to prove to them the value of deep ploughing and abundant manuring!

Soon after reading Dr. Cloud's communication, last spring, I had a piece of tolerably good hill land, containing three acres, three rods and thirty-five poles, cleared off the previous year's trash—some 200 bushels of manure, per acre, added, consisting of the scrapings of the cow-pen, partly decayed cotton seed, and so on. This I scattered broadcast; then threw up ridges, which average, from centre to centre, five feet four inches; then harrowed down by running a heavy harrow lengthwise of the ridge. Here I planted some very superior gulf-hill seed, presented to me by Mr. Compton, Sen., near Rodney. The seed I first dampened pretty well with brine, and then rolled in dry ashes—dropping some ten or fifteen seeds at about every 26 inches, which were afterwards thinned out to a single plant.

I am not certain of the amount of labor bestowed upon this piece of ground—the *tending* was the same as that given to the rest of the crop; further than that, my overseer, Mr. Ventriss, has repeatedly said to me, that he had not one half the trouble with the grass on that piece, that he had with any other part of the plantation—"that the grass did not trouble him there." I *rather* think that it *did* trouble some of us this year! This was, of course, to be ascribed to *the deep ploughing*.

Now, gentlemen, from the (scant) *four acres* of ground, Mr. Ventriss assures me that he has already picked, 7,325 lbs. of superior seed cotton; and that there is yet cotton enough open, and to open, to yield over 2,000 lbs. more. I know that he has been very particular, both in picking and weighing, and have every reason to believe his report to be correct.

Now here we have, on a first hurried experiment, 9,325 lbs. of seed cotton from (scant) four of ground; or allowing 1,330 lbs. to make a bale, (and as it is a very fine article, I think it a fair allowance.) we have seven bales of ginned cotton!

I leave it to yourselves to draw your own conclusions, as to the amount of time, labor and manure, that one *could very easily afford to bestow* upon such a small tract of land, to produce such a result! It required at least 12 acres of the same land immediately adjoining, treated, planted and tended in the usual way, to yield as much cotton; and the staple is, *to my eye*, not nearly as good.

Western Farmer and Gardener.

NEW METHOD OF MAKING MANURES.

We published the following article some weeks ago, but having been called on by several friends for copies of the paper containing it, which we were unable to furnish, we concluded to re-publish it, and as the experiment can be made with little trouble or expense, we hope they will give it a fair trial and report the result for publication.—*Ed. R. Star.*

1. Form your barn yard with a gradual descent to one side, so that the liquid formed by the rains will flow gently to that side: make the bottom as hard and smooth as possible, that there may be little or no waste by soaking into the earth. Arrange your stables, hog pen, &c., in such order, as to throw all the litter and manure into the yard.

2. Sink a vat or reservoir to the lower side of the yard, of sufficient capacity to contain the juice of the yard. The most common form of the vat is six feet width by three feet deep, and twelve or more in length, according to the size of the yard, and the amount of liquor flowing from it. When the vat is more than twelve in length, it will be best to divide it by partitions into two or three parts, so that if at any time you want to use only part of the liquor, you can do so without any inconvenience. It will be further desirable to have the vat so connected with the yard, that when once full, and you have commenced your manufacture, if additional rains come before you shall have completed your heap, of which we shall soon speak, you can prevent the liquid so formed from running into your vat, either by keeping it back in the yard, or by turning it another direction.

3. In this vat mix the following ingredients as nearly as you can, without actual measurement or weight: to every barrel of liquid add 4 lbs. of stone lime just slacked, 4 lbs wood ashes good quality and dry, or an equivalent of leached ashes, or 1-4 lb. of salt, or its equivalent of brine; 2 ozs. salt petre; 20 lbs. plaster of Paris, or mud, or muck; 10 lbs. of excrements from the privy, or 20 lbs. of horse manure. Mix these ingredients thoroughly with the liquid in the vat, and if the vat contains one hundred barrels, increase the above ingredients an hundred fold. It would be well to mix these ingredients a few days before you lay up your heap, and stir them every day, but this is not essential.

4. On the upper side of the vat lay the foundation for the heap, by placing poles or rails, with one end to the vat, and the other extending from it, about 2 feet apart; on these lay other poles crosswise, (precisely as we do the foundation for a stack of hay or grain) to keep the straw from the ground, and that the liquid may flow freely beneath.

5. Having every thing prepared, commence laying up the heap by placing a layer of straw, weeds, stalks, or whatever you have at hand, on the foundation of poles, to the thickness of a foot. You will find great advantage from throwing the materials as you collect them in the yard and letting the cattle tread on them, until they are thoroughly wet. When the layer is a foot thick, stir up the ingredients in the vat and with a pail or other vessel, thoroughly wet the layer on the poles. Place another layer on the first, and of the same thickness wet as before, and thus continue until you have raised the heap as high as you wish---say from six to ten feet. Be careful at wetting to stir up the ingredients from the bottom of the vat. The easiest and quickest way to wet the several layers, will be to use a pump, or elevate, with a hose attached, to spread the liquor over the heap. In such a case, let one stir, another pump, and a third manage the hose. Only be careful, whatever method you pursue, to wet the several layers thoroughly in all their parts. When finished, cover the heap with settlings in the bottom of the vat, or with anything else at hand---common earth will answer.

6. If the heap consists of straw, weeds and the like, it will require wetting every fourth day. If you have used much peat, muck, or earth, with the straw, water once a week. To water the heap, make holes with an iron bar or other instrument in the top of it, from eight to twelve inches apart, and extending downward about to the middle; then stir the liquid in the vat, and pour it into the holes until the hole is saturated; finally close the holes. At every watering make new holes.

Give the heap three waterings when made of straw, and it will be fit for use in fifteen days from the time of laying it up, when much muck or mud has been added, thirty days.

When it is desired to manufacture this kind of manure in places where barn yard liquid cannot be readily obtained, river, spring or pond water, will answer the same purpose for wetting the heaps as the barn yard liquid, by increasing in a small proportion, the ingredients for the mixture, as given in section 3, and adding them to it.

Raleigh (N. C.) Star.

LIME.

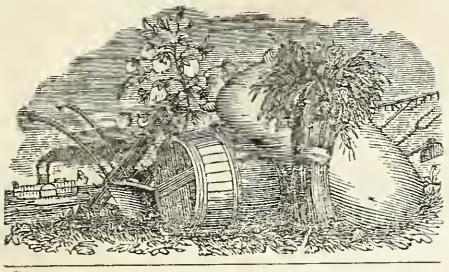
A gentleman in Virginia said, three years ago, that he had taken the Cultivator one year, but would never take it again. But why this hostility to the Cultivator? Is it not the farmer's friend? "Yes, it had my confidence; it recommended the putting of lime on land, and I followed the recommendation, and lost fifty dollars by it. I put on 80 bushels to the acre, and it is all lost, worse than lost, for it injured the land."

But what is the sequel of the case before us? Why, the lime has had time to be well mixed with the soil, has proved itself to be equal to all that was claimed for it in the once execrable article, and the gentleman now thinks he will not be fifty dollars the worse but one thousand dollars the better for taking the Cultivator. It is needless to tell you he is now an advocate for agricultural papers.

Permit me here to mention another instance of the value of calcareous manure. Major A. Stuart, Augusta county, Virginia, four years ago, gave a part of a field a liberal dressing, (the quantity per acre I don't know,) of marl, which is abundant on his farm. The first year he noticed its effects carefully, hoping to see an improvement in the crop, but he was disappointed, for the effect he thought was rather injurious; and being thus disappointed, he concluded the marl was worthless to him, and don't recollect to have noticed any effect from it the second year; but the third year he was called upon by such visible tokens of improvement in the c'over crop, which was on the field, that he could no longer be indifferent about the marl. This year, the field being in wheat, he found the improvement still greater, the difference being as three to one in favor of the marled portion of the field, and this difference being attributable wholly to the action of the marl. This soil is a ferruginous clay, abounding in lime rock, which, as you are aware, is the case with most of the land in the valley of Virginia. Is it not a general opinion, that on limestone land calcareous manures are not beneficial?

Cultivator.

BEES.—To prevent the moth laying its eggs under the hive, I have for the last several years cut a mortise in the bench about an inch deep and about two inches larger than the hive, and the hive is then set in this mortise, and the space of about one inch all around it is filled with mortar, then three-inch auger-holes are bored in the hive about two inches from the bench, for the egress and ingress of the bees, and a small auger-hole through the bottom of the bench to let off water. should any get under the hive. I have near night watched the moths, attempting to enter through these holes, and seen the bees chasing them away.—*Southern Planter.*



WEDNESDAY, FEBRUARY 21, 1844.

THE BACK VOLUME.

All new subscribers who may desire it, can obtain the first volume, neatly bound in boards, at one dollar the volume.

W. W. Bates, of Eufaula, Barbor county, Ala., writes us thus:

The neighborhood in which I live, have lost a great many hogs and cattle, during the last fall and the present winter, by turning them into pea fields. Peas grown upon the hammocks, as well as upon the uplands, have been alike destructive to stock. If a remedy cannot be given, we shall have to abandon the raising of peas. If you or any of your readers know a remedy, please inform us through the Cultivator.

The destruction of hogs and cattle, by turning them into fresh pea fields, is not very uncommon. The remedy, however, is very simple. Stock, immediately before being turned upon a pea field, should be watered, and at first only be permitted to remain in the field a few hours, when they should be removed to a lot, and have free access to water. After observing this precaution twice or three times, they may be permitted to remain in the pea field constantly, without danger, if they have free access to water.

To ascertain the weight of a Hog.—Mr. John Farrar, of Putnam county, furnishes us with the following method of ascertaining the weight of a hog, which may be of use to those who have a hog too heavy to be weighed by any steelyards at their command. He says it is sufficiently accurate for all purposes, except in buying or selling the pork:—"Cut the head off in the usual way, about 1½ inches behind the ears—weigh the head and multiply by ten, and the product is the weight of the hog. I have tried it frequently, and have found it correct to a fraction oftener than otherwise."

Mr. Editor—Believing that it will afford you a high degree of satisfaction to learn that the circulation of your paper among us, is exciting much greater interest in the subject of agricultural improvement than has been manifested heretofore, I take pleasure in communicating the intelligence, and to assure you that among its readers a general inquiry has been excited, and a disposition to adopt a more enlightened system of management evinced.

This augurs well for the success of your efforts, and I trust a similar spirit may be infused into the citizens of every county and neighborhood. We may then calculate with certainty that the day is not far distant when our people will be contented and happy, while their fields are teeming with the abundant harvests of an enlightened system of agriculture.

Pardon the digression, Mr. Editor, and indulge me in a few brief remarks to my brother planters, on a subject which not only interests them, but the entire country. We are rapidly passing from a period of almost unexampled depression to one of glowing prosperity—and it is to be feared, greatly feared, that we will, in the full tide of successful experiment, too soon forget the scenes through which we have just passed. "Times are getting better with us," is a remark which meets our ear almost every hour. 'Tis true as 'tis commonplace—every class of society and every branch of business attest its truth—property of all kinds is rapidly advancing in value—confidence is restored, and men are daily embarking in new enterprises, or seeking new investments for their capital. This is no imaginary picture, and I need only mention one species of property in support of its truth: slaves are from 30 to 50 per cent. higher than they were twelve months ago. What I desire, then, is to speak to my brother planters in a voice of warning—to admonish them, ere it is too late, to avoid the dangers attendant upon such a state of prosperity. To many, such an admonition need not be given: they are already forewarned, and therefore forearmed. But there are others to whom it may be beneficial—for I fear there are too many men who, like the schoolboy, forgets his lesson of yesterday, however well he may seem to have understood it while reciting. My advice to all such is, look back, survey again and again the scenes of depression and misery and want, through which we have just passed, and be certain not to forget the lesson which the results of a few years of prosperity have taught us. Going in debt in prosperous times, may be justly compared to a man navigating a boat on a smooth current down stream—it requires little effort, and all is bright while the water is undisturbed by a commotion of the elements, or unchekered with shoals or rapids: he floats on, unconscious of the danger which is so soon to overwhelm him—and when once in debt, and reverse after reverse succeeds each other in rapid succession, and he is compelled to pay those debts which have been created in prosperous times, by the hard earnings of his labor, when every thing is depressed—he may be justly compared to the same navigator, pushing his boat against a strong current in rapids among shoals: danger and ruin stare him in the face at every step: he has no repose, no quiet—but his labor is one of increasing diligence. If an oar or pole give way, the boat is driven back by the force of the current, and a double effort becomes necessary to regain his lost position—and he escapes, if ever, worn down and exhausted with the perplexity and vexation of spirit.

Mr. Editor, we are just emerging from the shoals of adversity, and our future voyage promises a rich reward to the provident! Let us, then, beware! beware!

A Friend to Economy.

A printed thought never dies. Nothing is so indestructible. The proudest works of art crumble to dust, but the eloquent thought lives, and will live down to the end of time.

Agricultural Debating Society.—The Sandersville (Ga.) Telescope says:—A highly commendable scheme for mutual improvement, has recently been adopted by some of our farmers in this neighborhood, in the shape of a Debating Society—in which questions of agricultural policy, alone, are debated. It strikes us that no more desirable plan could be hit upon, than this, for the dissemmination of useful information among practical farmers.

THE FARMER'S LIFE.

The following extract from the address delivered by the Hon. Mr. Saltonstall, before the Essex county (Mass.) Agricultural Society, descriptive of agricultural pursuits, will be appreciated by every virtuous mind.

Agricultural pursuits in the open air, in the pure breath of heaven, and amidst the works which God has made, have the most purifying and elevating influence on the heart and mind. Who that has a heart in his bosom, can look abroad on our hills, crowned with trees, our pastures covered with flocks, on our valleys and plains, laden with "food for man and beast," and not think and feel, how good God is? Who can behold the meadows ornamented with flowers, and reflect that the wide spread prairies, the solitary wilderness, nay, that the whole earth is strewn with an infinite variety of those most lovely objects, arrayed with more beauty than was Solomon in all his glory, and his heart not be softened into a sense of that boundless love, which has made such provision for our enjoyment, and for the gratification of a pure and refined taste? Who can see the sun rising in his glory, as all good farmers are wont to do, or can behold him sinking in his gorgeous pavilion—who can look upon the magnificent heavens, which can only be seen in the country, and not feel awed into reverence before Him who made all, and exclaim as did the shepherd of Israel—"When I consider the heavens, the work of thy hand, the moon and stars which thou hast ordained, what is man, that thou art mindful of him, or the son of man that thou visitest him?" Who can listen to the "charm of earliest birds" as they dart from their nest and mount to the topmost sprays at dawn, and not join their notes of grateful praise to him who notices the sparrow's fall, and whose providential care extends to all his works? And where shall we learn our dependence on divine providence so effectually, as in an occupation where his visible presence seems manifest, in his imparting the influences of the sun and o showers in such succession as to crown with success the labors of our hands—who withholds the needful blessings only so long as is necessary to make us feel, that "it is God who giveth the increase."

Farmers of Essex, you cannot render a greater service to your country, than by disabusing the public mind of any prejudices which still remain as to the true character and influence o your pursuits.

"Such themes as these the rural Maro sung
To wide imperial Rome, in the full height
Of eloquence and taste, by Greece refined.
In ancient times, the sacred plough employed
The Kings and awful fathers of mankind;
And some, with whom compared, your insect tribes
Are but the beings of a summer's day,
Have held the scale of empire, ruled the storm
Of mighty war: then with unwearied hand,
Disdaining little delicacies, seized
The plough, and greatly independent, lived."

A Piggery.—A "long-drawn aisle" extended from end to end of this establishment, along the middle; and on either side of this aisle were suits of rooms for the different madams and their young families of porkers, the troughs being on the side next the aisle, so that each apartment could be fed from the centre. The entrance to each apartment or pen, was by a gate opening on the outside.

Southwestern Farmer.

QUANTITY OF LIME PER ACRE.

We have repeatedly taken occasion to advance the opinion, that a much less quantity than 100 bushels of lime, per acre, would answer for all present purposes—and we have as often stated that an application of 25 bushels, if repeated at the expiration of each rotation of four years, until one hundred bushels had been applied per acre, would be better than applying that quantity at a single spreading; first, because the lesser quantity would be more than sufficient to meet all the demands of the crops for a period of years; and secondly, because, as the *outlay* would be diminished three hundred per cent, a much larger quantity of land could be dressed with it, and the farm, therefore, at an earlier period, and at much less expense, be brought into a state of profitable fertility. And as the *heaviness of the cost* forms a very serious objection to many persons undertaking the liming of their lands, we shall state a few of the many reasons which induce us to adopt the views of the subject we have heretofore felt it to be our duty to advance.

From the tests of analysis, it has been very clearly ascertained, that the crops, in a four years rotation, extract from the soil, on an average, about 242 lbs. of lime, which is 60½ lbs. per year. Some crops, we are aware, require more than others, but the average is set down as we have before stated. If, then, it requires but 60½ lbs., which is less than a bushel, to supply the plants grown on an acre, in a year, with the proper quantity of this particular kind of food, the inference is a fair one, that unless a *mechanical amenament* of the texture of the soil be an important object with the improver, there can be no positive necessity for the use, at any one time, of 100 bushels of lime upon a single acre, and the deduction is equally *fair*, that, as less than a bushel is given out in food to the plants in any one year, it would be preferable to use the hundred bushels on four acres, instead of one. By this division of he largest quantity named, the improver would be enabled by the increased products, to carry on his liming, and thus relieve himself from much of the onerousness of outlay, where heavy dressings are at first given.

Practical observers, as well as scientific men, have affirmed, that *visible good effects of lime* have been witnessed thirty years after its application; and we have no doubt of the fact. For, although much is lost to cultivation by the tendency of the mineral to sink beyond the reach of the roots of most growing crops, yet it must be obvious that, if less than a bushel is annually taken up by the plants, an application of one hundred bushels to an acre would last for a period greatly beyond thirty years. The question then resolves itself into this: If 25 bushels will answer for a series of years, equally as well as an hundred, why should the heavy expense of the latter be incurred. We make this suggestion purely as a matter of *economy;* and not because of any fears we entertain that a hundred bushels per acre, could, under any circumstances, operate disadvantageously to the soil, provided there were sufficient organic remains in it for the lime to act upon, or that animal and vegetable manure were applied, or green crops ploughed in. Lime, as a means of restoring fertility to an exhausted soil, is among the most efficient agents which can be used; and we hold, that without it, no permanent melioration can be effected, and for these simple and obvious reasons—all analysis prove that lime is to be found in the ashes of most of the vegetable productions, and therefore forming, as it does, a part of their food, it is essential that it should be in the soil, in order to secure a healthful growth of the plants raised thereon.

American Farmer.

Always have some worthy end in view, in whatever you undertake; remembering that to fail with good intentions, is more honorable than success in an evil cause.

AUGUSTA MARKET.

TUESDAY P. M., February 20.

Cotton.—Our market, for the last few days, has been in such an unsettled state, as regards the views of buyers and sellers, that very little has been done—and that little at rates so irregular, that we omit our usual quotations. Both parties seem in a state of suspense, and have generally determined to await the arrival of the Steamer of the 4th instant, from Liverpool; the news by which we expect the latter part of the week. If this news is favorable, it will give stability to our market, otherwise it will be greatly depressed.

Exchange.—Bills on New York, Charleston and Savannah, are abundant at par. Central money continues steady at 3 to 4 per cent. discount. We hear of no transactions in State 6 per cent. bonds, which seem to drag rather heavily upon the market.

TO HOG RAISERS.

THE subscriber offers for sale the JERUSALEM ARTICHOKE, which, by early application, can be obtained at his Store in Monroe, Walton county. The value of this article as food for Hogs, is no longer a matter of experiment or doubt. It has been fairly tested in Kentucky and Tennessee, and the Northwestern part of Georgia. They are required to be planted in the spring, and will be fit to feed in the ensuing fall and winter. I hazard nothing when I say not one-tenth of the corn now fed to hogs, is at all necessary; and, by the use of the artichoke, the use of corn, for hogs, may be entirely dispensed with through the whole winter. The first year, they are no more trouble than sweet potatoes: after that, they require no cultivation.

J. A. CLARK.

Monroe, Walton Co., Ga., Feb. 21. 2t

GARDEN AND FIELD SEED.

A GENERAL assortment of fresh and genuine GARDEN and FIELD SEED, among which are the following:

Red and White Clover,
Blue and Green Grass,
Rye and Orchard do.,
Timothy and Herds do.,
Millet and Luccrne do.,
Seed Corn of every valuable variety,
Seed Wheat,
Buckwheat and Potato Oats,

Kept constantly on hand by the subscriber, all of which are offered for sale at very moderate prices. All orders, by mail or otherwise, executed with neatness and despatch.

WM. HAINES, JR.,
No. 232 Broad street, Augusta, Ga.
August 30. 18-tf

CHEAP AND FRESH GARDEN SEED.—A large and select assortment of fresh Garden Seed, of this year's growth, (1843,) put up expressly for this market, and warranted genuine. Just received and for sale cheap by j9 tf WM. HAINES, Jr.

TURNEP SEED.

A SUPPLY of the following varieties of fresh TURNEP SEED just received, viz:

Yellow Sweedish or Ruta Baga, very fine for stock,
Large Globe Turnep, } Fine
" White Flat do. } for
" Hanover or White Ruta Baga do } table
" Norfolk do. } use.

For sale in quantities to suit purchasers, by
Aug. 30 18-tf WM. HAINES, JR.

THE SOUTHERN CULTIVATOR

IS PUBLISHED BY

J. W. & W. S. JONES,

And will be issued every other Wednesday.

TERMS.

The CASH SYSTEM will be rigidly adhered to, and in no case will the paper be sent unless the money accompanies the order.

ADVERTISEMENTS pertaining to agriculture will be inserted for ONE DOLLAR for every square of TWELVE lines, or less, for the first insertion, and SEVENTY-FIVE CENTS per square for each continuance.

☞POST MASTERS are authorized to receive and forward money free of postage.

☞ALL COMMUNICATIONS MUST BE POST PAID

☞*All subscriptions to commence with the volume.*

SOUTHERN CULTIVATOR.

VOL. II. AUGUSTA, GA., MARCH 6, 1844. No. 5.

From the New England Farmer.

EXTRACTS FROM MR. HUDSON'S ADDRESS

BEFORE THE WORCESTER AGRICULTURAL SOCIETY.

Connection between Agriculture and other Interests.

"Although agriculture is one of the earliest employments, and an essential ingredient in civilization, it is by no means an independent calling. Every human pursuit, like man himself, is dependent upon its fellow. Agriculture, manufactures, and commerce, the three great pursuits of mankind, are equally honorable employments, all conducive to the public good, and each essential to the prosperity of the other. Commerce could not exist without agriculture and manufactures. Unless the sails, the cordage, the anchor, the ship itself, were manufactured, how could the ocean be traversed? Without agriculture, how could the hemp be grown, the ship provisioned? And what is the cargo of the merchant but the products of the soil, or the fabrics of the workshop? Commerce is entirely dependent upon agriculture and manufactures. The ship could not be built without the mechanic; the canvass could not float without the assistance of the plow.

There is also an immediate and inseparable connection between agriculture and manufactures. The mechanic must furnish the tools—must manufacture the implements of husbandry, or the labors of the husbandman will fail. The plow must be constructed before the furrow can be turned; the scythe must be manufactured before the grass of the meadow can be laid low. But what calls for the construction of the plow, the scythe, or the sickle, but the wants of the husbandman? And what sustains the mechanic while constructing these implements, but the products of the soil? The mechanic or manufacturer could not subsist without the produce of the farmer; the farmer must have the tools, the clothing, the shelter, furnished by the manufacturer or mechanic. Agriculture and manufactures are intimately connected, and whenever, by their mutual aid and succor, they rise and flourish, commerce becomes necessary for the interchange of their commodities. The man who, from undue attachment to either of these pursuits, would separate it from the others, that it might stand 'alone in its glory,' would show no more wisdom than he who, from partiality to one member of the human system, would separate it from the body, by which it is nourished and sustained."

Which should be the most numerous class, Agriculturists or Manufacturers?

"But although these great callings are important to the country, and mutually beneficial to each other, to be productive of the greatest good there should be a due proportion between them. Agriculture may be regarded as the parent calling. Upon the earth, as a nursing mother, the human family must mainly depend for sustenance. The agriculturists, therefore, should be the most numerous class. They are the foundation upon which all other laborers must rest.

It has sometimes been a matter of complaint by the farmers, that so many of our young men abandon agriculture, and engage in other employments. It may be truly a matter of regret, so far as the welfare of the young men is concerned, but the interests of agriculture are not impaired by this course. The profits of farming must depend mainly upon the price of produce, and this price will be regulated by the demand. Every one, therefore, who leaves agriculture for some other employment, by ceasing to be a producer, and becoming a consumer, increases the demand for agricultural products, which tends to enhance the price. How, then, is the farmer injured? He sustains no pecuniary loss whatever. The injury, if any is sustained, is done to the calling into which they enter; for a surplus is there created, which, to that calling, may prove detrimental."

Importance of a Market to the Farmer.

"The great object with the farmer is, to find a market for his produce. It is to no purpose that he raises more than he consumes, unless he can dispose of the surplus. And who are his purchasers? Not those engaged in the same pursuit with himself: they have generally enough and to spare. His purchasers must be found among the manufacturers and mechanics, the merchants and traders, and those engaged in other callings than agriculture. * * * Every thing which increases population, enhances the value of the soil, and promotes the interest of those who cultivate it. The price of land depends materially upon its proximity to a market. Go through the country, and you will see lands of the same intrinsic value, selling for agricultural purposes, at prices ranging from two dollars to two hundred dollars per acre, when the main consideration which affects the price is, their situation with reference to a market. Wherever or whenever a village springs up from manufacturing or any other cause, the price of land is increased for miles around. Not only do the great staples of agriculture increase in value by the proximity of a market, but a thousand little nameless articles assume a value unknown before. Gardening is introduced, milk is disposed of at great profit, the summer and fall fruit, before nearly useless, now command a good price, wood is quadrupled in value, and even the stones are converted into bread."

Attempting the cultivation of too much Land.

"The farmers generally attempt to cultivate too much land. The disadvantages arising from this cause, are many and obvious. It is no exaggeration to say, that the lands cultivated in the county are capable, under a high state of cultivation, of producing twice as much as they now produce. This applies, we will suppose, not to the pasturing, but to the arable land alone. The farmer, then, in the purchase of his land, might save, say, one-sixth of his original outlay in the reduced quantity of his arable land. The sum thus saved, would enable him, in the first instance, to put his land in such a state of cultivation, as would in a few years double his crops per acre. Nor would the annual cost of cultivating an acre of land in this highly improved state, be materially increased. The cost of plowing, planting and hoeing an acre of ground capable of producing fifty bushels of corn, would be no more than though the land were only capable of producing twenty-five bushels. * * Take the average of all the upland mowing in the county, and the yield will not probably exceed 1500 of hay to the acre. And three-fourths of this land is capable of yielding two tons to the acre. Let the farmers reduce the quantity of their grass land two-thirds, and they will find that, with skilful cultivation, they save one-half of the labor, and still obtain their usual quantity of hay. * * Let the farmers of the county reduce the amount of their cultivated lands, take special care to increase the quantity and quality of their manure, and adopt a wise rotation of crops, and they will soon find that lands which now 'mock their scant manuring,' would soon yield a plentiful harvest, and richly repay their toil. Let them adopt the best system of husbandry, and this would prevent the emigration of our farmers to the West. They would soon see that the rugged soil of New England, under skilful culture, is, when taken in connection with New England comfort, New England institutions, and a New England market, to be preferred to the more fruitful prairies of the West, where the productiveness of the soil contrasts so fearfully with the domestic comfort of the inhabitants, and the worth of their literary and religious institutions. Who, that reflects upon the subject, would be willing to exchange the comforts of a New England farmhouse, and the refinements of New England society, for the privations of a log-hut in the wilderness? Who would not endure the summer's heat and winter's cold common to our climate, rather than the burn and chill of the ague-fever?"

False estimation of Agriculture.

"The first obstacle in the way of agricultural improvement, which I shall mention, is the low estimate which has been put upon this calling. It has too often been regarded as an employment that requires nothing but physical power—mere brute force; and consequently, if a young man exhibited any considerable degree of talent, he must be put to some other calling. The natural tendency of this has been, to degrade agricultural labor, and to impress upon those who had any aspirations after distinction, the impolicy of groveling in the dust, as cultivating the soil has sometimes been regarded. The effect of this has been to draw talent away from agriculture, and to create an impression that the calling was not as respectable as some others. Many a young man has been driven from agriculture, and brought to ruin by this cause. And if it were not ungallant, I would say that some of our young women, faultless in every thing else, have been so far deceived as to prefer a husband employed in other pursuits than agriculture. But the reverses which have attended other pursuits, will, I trust, soon teach them that the permanent home of the farmer's wife is greatly to be preferred to the changing abode and variable fortune of many other classes of our citizens. * * Agriculture is no mean employment. It was the first into which our race entered, and it is the last which can be abandoned. It has commanded the attention of some of the wisest and best men of ancient and modern times. Cincinnatus, renowned in war, was not ashamed to follow the plow; and the estimate which posterity has put upon his worth is such, that the *farmer* has thrown the *General* into the shade. And in our own country, to mention but one example, the Farmer of Mount Vernon was the Father of his Country. Who, then, would disdain a calling pursued by the wise and the good—a calling essential to the well-being of society, conducive to public virtue, promotive of health and happiness, and one to which Washington was proud to retire, from one of the highest stations ever conferred by man. But modern discoveries have made ag-

riculture more attractive than formerly. Now the application of science renders it an *intellectual* employment; so that the laborer may improve his mind while improving his soil, and cultivate his heart as well as his farm."

We conclude our extracts with the closing paragraphs of the address, in which a merited tribute of respect is paid to the late Corresponding Secretary of the Society, Wm. Lincoln, Esq.:

"Gentlemen of the Society: Your calling, important as it is, should never be permitted to interfere with higher pursuits. There is a culture more important than that of the soil. The intellectual and moral field requires our utmost care. We are but plants, which rise and blossom and decay. That 'all flesh is grass, and the goodliness thereof is as the flower of the field,' is forcibly impressed upon us at this time, by a recent instance of mortality among the officers of this Society. In the death of their late Corresponding Secretary, the Society has sustained a severe loss. Actively devoted to the cause in which you are engaged, he brought the treasures of his rich and well-cultivated mind, and laid them a willing offering at our feet. No duty was too arduous for him to perform—no sacrifice too great for him to make in the cause of agriculture. Attached to your Society by sympathy, by long and active labor, he was one of your most valuable members—among the most faithful of your officers. No want of the Society ever escaped his attention: he preserved all her interests with a fostering care. His labors always contributed to the interest of our exhibitions; and his presence on each returning anniversary, was hailed with joy by a large circle of devoted friends.

But the heart which was warm with every generous emotion, has ceased to beat. The tongue which could instruct or amuse us, is silent in death. The place which he filled with so much honor to himself and profit to the Society, is now vacant. We shall see our friend no more. But as long as courtesy and kindness are regarded with favor; as long as talent and genius command our respect; as long as benevolence and generosity deserve our commendation, or industry and fidelity are esteemed as virtues, the memory of WILLIAM LINCOLN will be cherished."

From the New England Farmer.

DANA'S PRIZE ESSAY ON MANURES.

Extract from the Report of the Committee appointed by the Trustees of the Mass. Society for Promoting Agriculture, to award the Premium for the best Dissertation upon Manures, and their application to the various Soils in this Commonwealth.

The author of the following Essay upon the application of Chemistry to Agriculture, is known to be one of the most scientific and best practical chemists of the country; a man of genius; a gentleman, too, who has done more to advance the science of Chemistry as applied to Agriculture, than any other man in America. It is intended to be written in plain language, such as most farmers can understand, if they give their attention to it. The principles laid down are generally such as are well established, and no longer doubtful. The great object, however, of the Essay is, to bring into more general notice a theory, and a practice growing out of it, suggested some years since by the author, which has received the sanction of some of our practical farmers, who have tried it under his direction.

If the author is correct, common peat, when mixed with soda, potash, or ammonia, in the proportions given by him, would be, on most soils, equal, as a fertilizer, to the common manures used by the farmer.

Should his views be hereafter fully sustained by experiment, it will lead, we think, to the greatest improvement that has ever taken place in the Agriculture of the State. A cord of peat earth can often, with us in Massachusetts, be obtained from the meadows, as easily as a cord of manure from the barn-cellar; and one dollar's worth, or twenty pounds of soda ash, would, according to the author, make the one equal to the other.

The theory on which the author founds this practice is, that potash or soda may be substituted for each other and for ammonia in the compost heap, without detriment. To this theory we cannot, at present, subscribe. But whether they adopt this theory of the author's or not, most of our farmers who may read this Essay, will, we believe, receive both profit and pleasure from the perusal.

We therefore recommend, that the Society's premium of *One Hundred Dollars*, be given to Dr. Samuel L. Dana, for the best Dissertation upon Manures, and their application to the various soils of this Commonwealth.

—

ESSAY.

SECTION FIRST.

Clearing and Breaking up, and making Compost.

There is one thing settled in farming—*stable manure never fails.* It always tells. There are no two ways about it. There is here neither theory, nor speculation, nor doubt, nor misgiving. "Muck it well, master, and it will come right," is an old proverb. It is considered a fact so well established, that nobody thinks of disputing it. There is advantage in asking *why* barnyard manure never fails. The answer is easy: It contains all that plants need for their growth. If we know, then, what plants contain, we can easily tell what is in manure. The whole doctrine of manures, then, falls into two plain principles, on which hang all the law and the "*profits*" of agriculture.

1. Plants contain and need certain substances which are essential to their growth.

2. Manure contains all those substances which plants want.

If, then, we would find out what it is which manure contains that makes plants grow, we must first find out what a grown plant contains. This cannot be done without some little, a very little, knowledge of chemistry. Do not be startled, reader. I suppose that you may know nothing of chemistry—no, not even its terms.—As a very sensible man, who wrote letters on Botany to a young lady, said, to encourage his pupil, it was possible to be a very good botanist without knowing one plant by name, so is it possible to become a very good agricultural chemist without knowing little more than the chemical names of a very few substances. You know nothing of chemistry, it may be, and as little of law; yet you will go to law, and learn some of its terms by a dear-bought experience. The law terms are harder to learn than the chemical terms. Now I fear that some persons who have followed me thus far, will shut up the book. It is, they say, all stuff, book-farming, and beyond us. If one may not understand what manure is without this learning, we may as well begin where our fathers ended, and that was where our forefathers began ages ago. By a little law, however, picked up as a juryman, or witness, selectman, town-clerk, justice of the peace—yea, perhaps, by hearing an indictment read—men do come to understand what a lawyer means when he talks. So, too, by a little chemical talk, a man may learn what a chemist means when he talks of oxygen, hydrogen, nitrogen, chlorine, and carbon; potash, soda, lime—(all these are old friends; the very names make us feel at home again)—alumina, magnesia, iron, manganese, and silex, sulphur, and phosphorus. Here is a long list. Long as it is, perhaps it will be thought worth learning, when you are told that these are the names of all the substances found in plants—every substance which they want. Out of these is made every plant. Every part of every plant, from the hyssop on the wall to the mountain cedar, contains some or all of these. Be not disheartened. Look over, reader, the list again carefully; see how many are old names of things which you know. Of the fourteen, you know nearly one half by name and by nature. These are, potash, soda, lime, magnesia, iron, sulphur. Perhaps you will add, that you know carbon is coal, or rather coal carbon. You have heard, from some travelling lecturer at your town lyceum, that oxygen and hydrogen together form water; that oxygen and nitrogen form the air you breathe; that nitrogen and hydrogen form ammonia, or sal volatile, which gives the sharp smell to the smelling-bottle. Besides, the thing has been said so often, that you must have heard it, that chlorine, the substance which bleaches in bleaching salts, united to soda, makes common salt, or if chlorine is united to ammonia, sal ammoniac is formed. Now, by changes and combinations among these fourteen things, nature makes every thing we find in plants. Many of these are invisible to us, as is the air. The substance called chlorine, perhaps you have never seen, but if you ever smelt it you will never forget it. It is often smelt in a piece of bleached cotton, when opened in the shops. It gives the smell to bleaching powder, used to disinfect the air during cholera and other diseases. If you could see it, it would appear merely a feint yellowish green air. It is all-powerful on vegetation. As it forms a part of common salt, say half of its weight, we may dismiss the further consideration of it by saying, that, in some shape or other, chlorine is universally diffused in soil and plants.

The list above may be divided as follows: first, the airy or volatile; secondly, the earths and metals; thirdly, the alkalies; fourthly, the inflammables. Only the third and fourth divisions require to be explained or defined. The substances called potash and soda, are termed alkalies. They are said to have alkaline properties. Touch your tongue with a bit of quick lime, it has a hot, burning, bitter taste. These are called alkaline properties. Besides these, they have the power of combining with, and taking the sour out of, all sour liquids or acids—that is, the acid and the alkali neutralize each other. This word alkali is of Arabic origin: its very name shows one of the properties of alkalies. "Kali" is the Arabic word for bitter, and "al" is like our word super—we say fine and superfine; so kali is bitter; alkali, superlatively bitter; or, truly alkali means the "dregs of bitterness."

I wish, reader, for your own sake, as well as my own, that you should fix in your mind what I have said about alkali and alkaline properties. Alkali is a general term. It includes all those substances which have an action like the ley of wood ashes, which you use for soap-making. If this ley is boiled down dry, you know it forms potash. Now lime, fresh slaked, has the alkaline properties of potash, but weaker, and so has the calcined magnesia of the shops, but in less degree than lime. Here we have two substances, earthy in their look, having alkaline properties. They are called, therefore, alkaline earths. But what we understand chiefly by the term alkalies, means potash, soda, and ammonia. Potash is the alkali of land plants; soda is the alkali of sea plants; and ammonia is the alkali of animal substances. Potash and soda are fixed, that is, not easily raised in vapor by fire. Ammonia always exists as vapor, unless fixed by something else. Hence, we have a distinction among alkalies which is easily remembered. This distinction is founded on the source from which they are procured, and upon their nature when heated. Potash is vegetable alkali, derived from land plants; soda is marine alkali, derived from sea plants; ammonia is animal alkali, derived from animal substances.

Potash and soda are fixed alkalies; ammonia is a volatile alkali. Potash makes soft soap with grease, and soda forms hard soap. Ammonia forms neither hard nor soft—it makes with oil a kind of ointment used to rub a sore throat with, under the name of volatile liniment. But though there be these three alkalies, and two alkaline earths, I want you to fix in your mind, reader, that they all have common properties, called alkaline, and which will enable you to

understand their action without more ado about their chemistry.

The inflammables, or our fourth division, are sulphur and phosphorus; both used in making friction matches. The phosphorus first takes fire by rubbing, and this sets the sulphur burning. Now, the smoke arising from these is only the sulphur and phosphorus united to the vital part of the common air. This compound of vital air, or oxygen, as it is called, and inflammables, forms acids, called sulphuric and phosphoric acids. So if you burn coal or carbon, it is well known you form fixed air, or carbonic acid. That is, by burning, the coal or carbon unites with the oxygen or vital part of common air, and forms carbonic acid. The heavy, deadly air, which arises from burning charcoal, has all the properties of an acid. And now let us see what these properties are.

All acids unite or combine with the alkalies, alkaline earths, and the metals. When acids and alkalies do thus unite, they each lose their distinguishing properties. They form a new substance, called a salt. It is very important you should fix well in your mind this definition of a salt. You are not to confine your idea of a salt to common salt. That is a capital example of the whole class. It is soda, an alkali, united to an acid, or chlorine, or, to speak in the terms the most intelligible, to muriatic acid. So saltpetre is a salt. It is potash united to aquafortis. Yet in saltpetre you perceive neither potash nor aquafortiis. These have united—their characters are neutralized by each other. They have formed a neutral salt. Our list of substances found in plants, is thus reduced from things which you did not know, to things which you do know; and so we have saved the trouble of learning more of their chemistry.

We have reduced the airy or volatile into water, formed of oxygen and hydrogen; of volatile alkali, formed of nitrogen and hydrogen; or into acids, as the carbonic, formed of oxygen and carbon—as the sulphuric, formed of oxygen and sulphur—as the phosphoric, formed of oxygen and phosphorus; and having thus got water and acids, these unite with all the alkaline, earthy, and metallic bodies, and form salts. To give you new examples of these, I may mention Glauber's salts and Epsom salts. Glauber's salts is formed of soda and sulphuric acid; Epsom salts, of magnesia and sulphuric acid; alum, of alumina or clay, and sulphuric acid; green vitriol, of iron and sulphuric acid; white vitriol, of zinc and sulphuric acid; plaster of Paris, of lime and sulphuric acid; bones, of lime and phosphoric acid; chalk and limestone, of lime and carbonic acid. These are all examples of salts—that is, an acid, or a substance acting the part of an acid, united to an alkali, metal, or earth.

We have thus gone over, in a very general way, enough of chemistry for any one to understand the chemical nature of manure. You see, reader, that with common attention, bestowed for an evening's reading, one may learn these chemical terms and their meaning. And now, having learned this first lesson, let us review the ground gone over, and fix once and for all these first principles in our minds. Let us do this by a practical application of the knowledge we have gained.

Let us analyze a plant. Do not be startled at the word. To analyze, means to separate a compound substance into the several substances which form it. This may be done by a very particular and minute, or by a more general division. It may be done, for our present purpose, by separating the several substances of a plant into classes of compounds. You are already chemist enough to undertake this mode of analysis; in truth, you have already done it again and again. For our purpose, the ancient chemists had a very good division of all matter into four elements—fire, air, earth, and water. Now, by fire you separate plants into the other three elements. You are, reader, though perhaps you do not know it, somewhat of a practical chemist. Whenever you have burned a charcoal-pit, what did you? You separated the wood into air, water, and earth. You drove off by heat or fire the airy or volatile parts of the plant; you left its carbon or coal: if you had burnt this, you would have left ashes. Now, these ashes are the earthy parts of plants. If you burn a green stick of wood, you drive off first its water and volatile parts, which form soot. You burn its carbon, and leave its ashes or salts. So that, by simply burning, you reduce the substance or elements of plants to water, carbon, salts.

All plants, then, without exception, contain the several substances in our list above, as water, carbon, and salts. To apply this knowledge to manure, we must say a word on the form in which some of these, which we call the elements of plants, exist in them. The sap is water; it holds dissolved in it some salts of the plant. This sap or juice forms a pretty large proportion of the roots—say seventy-five to eighty parts in one hundred of potatoes, turneps, beets, &c. This may be called the water of vegetation. If we dry beet-root, or any other plant, we merely drive off this water of vegetation. Now what have we left? To go back to our process of analysis, let us char the dried root. We drive off more water and volatile parts. This water did not exist as such in the plant. It existed there as hydrogen and oxygen gas. Now, this word gas is a chemical term, and it means any substance in vapor, which cannot be condensed into a liquid or solid at common temperatures. Different gases may unite, and so become solids or liquids. Steam is not gas, for it is the vapor of water, and immediately returns to the state of water, below 212 degrees. Perfect steam is invisible; so are most gases. The air we breathe is composed of two gases, oxygen and nitrogen. We do not see them—we cannot, by cooling or compression, make air take other shape than invisible air. This is the general property of gas as distinguished from vapor or steam. Oxygen and hydrogen in plants exist in just the proportions to form water, but we do not know that they are united in these proportions. We have compelled them to unite by heating the substance or root. The carbon is by this same process consumed, and you know, has thus formed carbonic acid. Besides this, a portion of the carbon unites with some of the hydrogen of the plant. This forms light, inflammable air. Now you may collect this light, inflammable air, in any stagnant water where plants are decaying. Decay gives exactly the same products as are formed in making charcoal. Decay is only slow combustion or burning; no matter whether we char the plant or leave it to decay; we obtain exactly the same products as we did by our analysis, that is, carbon and salts.

But because there is not heat enough, we leave by decay a portion of the hydrogen and oxygen still united to the coal. A slow mouldering fire leaves products more like those of decay. Decay is a slow mouldering fire; hence the products of the decay of plants are very aptly termed mould. It is the product of a mouldering fire—that is, an imperceptible union of the oxygen of the air with the carbon of the plant,—a union so slow that it gives out neither heat nor light. And yet it is in its results the same as if fire had actually been seen and felt. Mould contains, then, a part of the carbon, oxygen, and hydrogen; or, if you like the terms better, mould of soil consists of the water and coal and salts of the plants. Mould is truly manure. If the mould of soil, as it has thus been defined, were separated from the earthy portions of soil, it would deprive that soil of the power of growing crops. Here, then, we come to a broad distinction between soil and manure. The soil is the earth on which plants grow. The mould is the manure of that soil. The soil is the earthy; the mould, that is, the carbon and salts together, with the elements of water, are the vegetable part of arable land. But though the earthy part, the soil, as it is usually called, acts as a support, on which plants grow, it does not play a merely mechanical part. It has a distinct, decided, and important action upon the manure. The action is chiefly chemical; and the fact that soils and manures do mutually affect the growing plant, is proved by the circumstance, that the first plants which grew, derived their salts from the earth.

But this chemical action of soil does not belong to the present discussion. We can understand what manures are, without deciding how they act. We can theorize and guess about the how of their action when we have learned what they are. That is chiefly what the farmer wants to know. He wants to know what manure is, and what is likely to act as a manure. To these points we shall confine our present remarks. Pointing out the great principles applicable to all manures, the nature of soils, and the manner in which they affect manures, must be left for another essay. The vegetable or manure part of soil alone is to be now considered. Consider, now, reader, the great results to which our analysis has led us; that a slow, mouldering fire gives us the same products as are formed by decay; that this is only a slow, mouldering fire, and that mould, its product, is the natural manure of plants. It follows, that whatever substance produces mould, that is, water, carbon, and salts, may be used instead of this natural manure. Among the salts found in mould, some are volatile, and are easily dissolved by water. Others are fixed, that is, not evaporating easily, or not at all, and are quite insoluble in water. Now the first, or volatile and soluble, first act when used in manure. They act quick and are quickly done. The fixed and insoluble act slower; they last longer. The volatile act in the early stages of growth; the fixed in the later periods. The great difference in the action of manures, depends almost entirely upon the salts which they contain. These are the most important and essential. It is not so much the vegetable mould of manure that you want, as the salts which it contains. This is a well settled principle. Land which has undergone the skinning process—old, worn out and run out land, still contains a very large portion of vegetable matter; the coal or carbon of mould without its salts. Give this worn-out land salts, and you may by these alone bring it back not only to its first virgin freshness, but you may even by salts alone make it fairer and richer than it was before man ever cultivated it.

Too much stress has been all along laid upon the kind of soil. Go now to "Flob," in West Cambridge: no better farms or farmers, look the world through. Ask any of these practical men whether the sandy and gravelly soil of Old Cambridge Common, or even of Seekonk Plain, can be made to bear as rich crops as their land? They will tell you, yea. If your land will hold manure, muck it well, and it will be as good.*

Now, this holding of manure belongs to the subject of soils, and throwing that out of consideration, it is found that even lands which do not hold manure, which have been worn out and exhausted by cropping, hold yet a great deal of insoluble coal or mould. They want salts, and something which will make this inert, dead vegetable matter of the soil, active. The mould is active in proportion as it is more or less dissolved by water. Mould consists of two parts; one is dissolved, though only in a light degree, by water; the other is not dissolved by water. Some substances, however, do render mould very easily dissolved by water. Hence, if you reflect a moment on these facts, it will be seen that mould itself, being valuable in proportion to the ease with which water dissolves it, that whatever substance so enables mould to dissolve, may be added to it, and thus increase its value. Now the things which do this are the alkalies, soda, potash, and ammonia.

These principles being well settled, we may enter on the consideration of each different ma-

*The reader will bear in mind that Dr. Dana uses "muck" as a general term for manure—not meaning simply the muck of the meadow.—Ed.

nure. They will be valuable in proportion to the quantity and kind of salts each contains, added to the power they may have of producing by their decay substances which make their mould soluble. Now, this last property, that is, the property of producing a substance which makes mould soluble, depends wholly upon the nitrogen of the manure. This nitrogen, in the process of decay, becomes volatile alkali, or ammonia. The word ammonia will occur so often in the present discussion, that we should endeavor to fix some definite idea to it. You need not, reader, be acquainted with all its chemical properties. I suppose every man who will be likely to read these remarks, has smelled ammonia. It has been already said, that it gives the peculiar pungent smell to the common smelling bottle. This is volatile ammonia. It is always formed when animal or vegetable bodies decay.

It has been already said, and is now repeated in order that it may never be forgotten, that ammonia is formed by the union of hydrogen and nitrogen. Hydrogen and nitrogen, two airs—nitrogen forming four-fifths of the air we breathe—let that be borne in mind, and without going into the chemistry of ammonia further, or the mode of calculating how much ammonia a pound of nitrogen will make, it may be laid down, and must be remembered, too, that every pound of nitrogen may be called two and a half pounds of sal volatile, or smelling salts of the smelling-bottle. Two and a half lbs. of volatile ammonia formed from one lb. of nitrogen. If, then, we can determine, as chemistry may, how much nitrogen exists in or forms a part of manure, two and a half times that will be the ammonia of that manure. If, then, the vegetable part of manure is, as we have said, valuable and active in proportion to its degree of being dissolved by water, then, as ammonia gives it this easy solubility, we may safely say that the quantity of nitrogen in manure, is the measure of the value of its vegetable part. One thing must be guarded against; not to place from this view the whole of the value of manure upon its ammonia. Remember that manure consists of carbon, water, and salts. The whole are equally essential to its action. There is no eye, nor ear, nor foot, nor hand, in manure, which may say to the other members, "I have no need of thee." The whole act together; but it is not to be doubted that ammonia is the heart of manure, and keeps up the healthy circulation among the other members.

PREMIUM ESSAY ON THE CULTIVATION OF CORN.

BY GEORGE W. WILLIAMS.

1. This Essay, although, in its application, it is intended for the Northern part of Kentucky, in its general principles may be adopted in all regions where corn can be produced.

2. Indian corn was not known in Europe till after the discovery of the New World. It was at first found by the followers of Columbus in South America, and it is supposed to have been cultivated in Mexico and Peru from time immemorial. It was introduced into England about the year 1505, is now cultivated wherever climate and soil are suitable, and is one of the most munificent gifts of the new to the old world. It is one of the staples of the United States, and in the great valley of the Mississippi is, next to cotton, the most important production of the soil. In the States of Tennessee, Kentucky, Missouri, Indiana, Illinois and Ohio, it is a product upon which the agricultural community relies for sustenance more than any other. It supplies to man and beast the most nutritious food, and it enters so completely into the economy of rearing stock, that it is believed a substitute cannot be found for it.

3. It is useless to raise corn upon poor or exhausted land. Land which is not fertile enough to produce 100 bushels to the acre, should not be planted in corn. To cultivate it in soils, which in the best seasons will not yield more than twenty-five bushels, and in ordinary seasons not more than twenty-five bushels to the acre, is an expenditure of labor to little purpose, and exhausts the soil in a ratio proportionate to its poverty. The best lands should always be selected for corn, and then if properly cultivated, such an average crop may be expected, as will amply repay the farmer for his labor.—Exhausted land put down to grass can be made more profitable by a proper system of grazing, than if kept in cultivation, and may be rendered in a few years as productive as the best.—One of the greatest errors in the present mode of cultivating corn, is to be found in the quality and quantity of land we undertake to cultivate. It takes many acres of poor land to make many barrels of corn: hence, we plant more than we can manage, and the result is much labor and a small crop. Good land, well cultivated, will yield heavy crops with half the labor. To correct this error, the attention must be turned to the improvement of exhausted lands, and to a more careful cultivation of those that are good, as well as to such a rotation of crops as shall keep the soil from deterioration. These subjects are not strictly within the scope of this essay, and will not be farther noticed.

4. There are many varieties of corn, and the farmer, in the choice of his seed, will have an eye to his location, the nature of his soil and climate, as also to the purposes to which he intends to apply the crop when matured. In Northern latitudes, the long-eared variety with large cob will not do, because it ripens slowly, and is liable to be injured by the frosts; and even here, it not unfrequently happens that varieties of this sort are overtaken by an early frost. If bread be the object, the best is a white, firm grain, easily shelled, and one that yields a pure white meal. In this, the farmer will, however, be governed by his own fancy, though experience will teach him that certain varieties are to be preferred for certain soils, and for particular purposes. My own judgment has led me to the cultivation of two kinds, one for meal and the other for stock, the latter of which has a small red cob, firm, deep, yellow grain, shells easily, and has commonly two ears to the stalk.

5. When the variety has been chosen, much care is to be exercised in the selection of seed, for it is an important consideration to have seed which will be sure to germinate; and will throw up a strong green plant from the start. Corn for seed should be of the best part of the crop as it stands in the field, and should be left standing until it has fully ripened. Let it then be taken from the stalk with the shuck on, and cribbed; or, if it is shucked, let it be kept in a dry airy loft. Most usually, where a stalk bears two ears, the top ear is the larger and better of the two. When the season for planting arrives, the whole is to be overhauled, and no ears should be chosen but those which are perfectly sound, and of good size for the sort. The grains must then be taken from each end of the ear, and those of the middle used for seed. I would recommend the grain to be planted as it comes from the ear, without any preparation to guard against insects or birds. The receipts offered for this purpose frequently injure the germ, and sometimes do more harm than either bird or insect. The best remedy against both is to plant early, and use sound seed. The character of the variety may be changed by a continued selection of the top ear from stalks bearing more than one ear, and if this be repeated for several years, the change, I think, will be for the worse. It will be found, although there will be an increase of the number of ears to the stalk, that their size will be diminished, the grains become shallow and flinty, and will adhere closely to the cob. I have, for several years past, made experiments of this sort, and ascertained that a continued selection of the top ear will produce these results. Baden produced his noted variety in this way, and I do not doubt but that it is greatly inferior to the variety from which he produced it. My plan now is to take the best ears whether first or second, and afterwards choose from among these, the most sound and perfect for seed.

6. I know of but one case in which it is proper for one crop of corn to succeed another, and that is upon land, which, being in sod, was prepared for corn with great expense and labor. In this case, the first crop, although it may be large, is not likely to be as heavy as the second, nor will it compensate for the expense of preparation. To prepare sod land for corn, it must be taken in hand early in the winter. As soon as the first thaw occurs after a hard freeze, it should be double-plowed, running one plow immediately after the other; the first turning over a thin surface of sod, and the one following, throwing upon that a thick slice of sub-sod, both plows together making a furrow from four to six inches in depth. I know of some excellent plows for this kind of work. My neighbor, Captain Wm. P. Hume, has in use a pair of his own invention that do the work to perfection. The Rugles's plow to be followed by Hay's Rounder, or with the Rounder, will do admirably. Sod land prepared in this way, mellowed by the latter frosts of winter, need, when the planting season arrives, only to be sirred with the harrow, before the seed is put in, and presents in fact the best possible prospect, if the soil is of the first quality, for a large yield.—Winter plowing of sod land is the only remedy against the ravages of the cut worm.

7. To prepare other lands for corn, whether stubble or fallow, deep plowing is the first desideratum, and the proper time for doing this, is as early in the spring as when the frost has left the earth, and it has attained a genial warmth, such as will cause the mould to leave the plow without difficulty. If stubble land be of a stiff, clay soil, and the stubble heavy, the stubble should be burned and not plowed in, but if it be of an open, light, friable description, the stubble should be turned under by all means. In the first case, the heat of the burning stubble will render the soil more friable, and the ashes will give that kind of manure best suited to it, while in light soils, the stubble soon decomposes, and forms an excellent nutriment for the growing crop. Before planting, the soil must be thoroughly pulverized, and to effect this, a harrow should follow the plow. To plow deep and well, the plowman must have a good plow, and one that will not choke. He must have a strong, steady team; he must walk in the furrow, hold his plow level, make no skips, plow from the middle out, turn his team to the right, move at a regular pace, make no stops, and keep always a constant watchfulness, that he is doing his work well. In plowing from the middle out, the team does not trample the plowed land in turning; the horses never get their hind feet, in turning, athwart the traces, and the team always has firm ground on which to turn. To plow, as is common, by commencing at the out edge of a field, plowing around the whole field and finishing in the middle, is objectionable, because in turning the team, four tracts to the extent taken up in making the turn, of trampled earth is made, from each corner of the field to the centre; or, if the plowman, to avoid this, rounds the corners so as to turn at each without a stop, he is, in doing this, necessarily compelled to make considerable skips, which is worse than trampling the plowed land. Land should never be plowed when it is so wet as to adhere to a bright mould board, or when it will not crumble. I do not approve of fall plowing of stubble land. From some cause unknown to me, fall-plowed stubble land is not as genial in the spring as it would be without such plowing, and besides, it is sure to be infested to such an extent with the white grub, as to render the crop very uncertain. If suitable seasons occur in the winter for plowing such lands, it will do well to plow them then, and it is better to do so, as a longer time is given for the decomposition of the stubble—but when the season of planting arrives, it must be plowed again, or listed by throwing two furrows into another.

8. The cast iron plow is to be preferred to all others, and for one reason alone. It is the most economical plow that can be obtained. I have in use, and am pleased with Hay's cast iron Rounder. When made bright, it works well and is altogether a superb plow. I want no better plow in stubble than it is, though it is not as good a plow as the Rounder, made by Rounder, of New Castle, altogether of wrought iron. I have one of his make: it is the best plow I ever saw in a stubble field.—Sloop's improved Peacock plow does excellent work in either sod or stubble. Cromwell's plow works well in both. The Carey is an inferior plow, and its use should be abandoned.

9. As to the time of planting, as a general principle, early planting is best. Most commonly, from the 1st to the 15th of April, is the most suitable period; but in this, it is to be considered that enough of warmth must be in the earth to cause the grain to germinate, on the one hand, and on the other, that if possible, the crop must be so far advanced as not to be injured by the drought of summer. In planting, I use a machine, and I cannot operate with it unless the ground is deeply plowed and thoroughly pulverized. It opens the furrow, drops and covers the seed, and rolls the ground by the same operation. With one horse, a man can, with this machine, plant eight acres in a day. It drops from four to seven grains in a place, and these places may be made at any distance apart, from two to four feet. In strong land, I plant four feet one way, and two and one half the other, leaving three stalks in a place. In weaker soils, I plant, of course, wider each way, and leave fewer stalks to a hill. The distance of the hills apart, and the number of stalks in a hill, should be regulated by the capacity of the soil. Lands, however, which will not grow two stalks in a hill four feet by three, ought to be put down to grass as unfit for corn. I never replant. Corn, planted by this machine, is not apt to be washed up by a heavy rain: it starts at its first growth from a surface level with the field surface, and at the first plowing can be approached nearer than when planted in the usual way. It can, however, be cultivated in one direction only. When this machine is not used in planting, the field must be checkered at the proper distances, and this should be regulated by the capacity of the soil. In laying off the rows the first way, let it be done with a two horse plow, and the furrow be made very deep; let it be crossed with a light single horse plow, that will make a furrow only half as deep. This will give a good bed of light earth at the intersection of the rows. The person who drops must be the most careful laborer in the field, and he must drop in the line of the rows which were laid off the first way. The seed may be covered with hoe, harrow or plow. The Bull-tongue or the single horse Dudley plow, will either of them do this work better and more rapidly than it can be done with the hoe.

10. In cultivation, I use these implements—the harrow, hand rake, hoe, plow and cultivator. They are all essential. When planted with the machine, as it can be cultivated in one direction only, the whole operation has to be done skilfully and at the proper season. If done right, the labor is comparatively small, and to accomplish this, it must be taken in time, managed with care, particularly in the commencement of the work. A deep furrow is to be run first between each row. This I do at the time I plant; and these furrows form a guide for the machine, and thus straight rows are obtained, which otherwise could not be by the machine. When the plants show themselves an inch or two above the surface, the two horse harrow is to be passed over each row, and this to be followed by a careful hand with a light rake, made with four iron teeth on one side and a small scraper on the other. He must uncover and raise up the prostrate plants, draw the clods from the hills, and throw, when it is necessary, a little loose earth among the plants. The next operation, which is to be done with the single horse plow and the hoe, is the most important of the whole series. I use the shovel plow. The plowman must exercise great caution; he must approach as near the plant as possible; he must keep constantly moving, but slowly and carefully, and must stop when his plow covers a hill and uncover it. He must plow deep. He must be followed by the hoe. The hoeman must thin the corn to the proper number of stalks, remove all obstacles, cut away weeds, cover all grass, and throw, when required, loose earth around the plants. If the labor is done well to this point and in good time, the after cultivation is easy. The grand object to be obtained, is to get a good stand, a loose bed of earth for the corn roots to occupy, and to have the hills free from weeds and grass. This being done, the cultivator is next introduced, by which the ground is levelled and weeds destroyed. Then if the roots of the corn have not extended too far, which will not be probable, the shovel plow is to be used, and as much earth is to be thrown with it upon the corn, as will cover all intermediate spaces. After this, the whole work is to be done with the cultivator, and two or three successive workings with it will be sufficient. I use the cultivator in after cultivation because it breaks no roots, and leaves the surface level, or as near so as is necessary. The roots of corn must not be broken, nor should any labor be done to the crop after the stalks begin to joint. I have seen fields of corn injured by firing, but I am, from close observation, satisfied that this never happens, unless the roots of the corn are injured in one or two ways, either by being broken up with the plow, and thus exposed to the scorching heat of the sun, or by being bound tight in a hard baked soil from the want of work at the proper time. This series may, however, be interrupted by what frequently happens, a season of rainy weather. If so, a sound discretion is to be exercised, but nothing is to be done, when the soil sticks to the hoe or plough in the mud—it is better to wait and make war upon the weeds afterwards, when the soil is light and friable. In this entire process, some things are of the utmost importance, and these I repeat, that they may be noted. The plants must get a good stand: from the start they must be kept free from weeds; the roots must have a loose bed of earth to occupy, and no form of cultivation is to be followed which interrupts the roots in their growth by breaking them, and by exposing them broken to the heat of the sun.

(To be continued.)

From the New England Farmer.

THE ADVANTAGE OF SCIENCE TO AGRICULTURE.

Mr. Breck:—I recollect seeing in a recent number of your well-conducted journal, an article commenting on an extract from one of the agricultural papers, in which the writer treated in a spirit of ridicule the idea of any advantage accruing to agriculture through the agency of "ammonia, alkali," &c.

It is strange, passing strange, to me, that men of apparent intelligence should be disposed rather to tickle the prejudice and bigotry of the illiterate, than to commend and encourage the enlightened efforts of those whose researches have resulted in devolving such important improvements—or truths which are the elements of improvements—as those which have been brought to bear so successfully upon agriculture within the space of the last quarter of a century. I say it is strange that such should be the fact, yet it is not uncommon. There are those among us—writers for the public press, too—who, as soon as a principle or deduction of science is recommended to the farmer for test, to see if it may not be of benefit to him in some particular case, are ready to prejudice him against it by the cry of "moonshine" or "humbug."

I frankly confess I have no charity for such persons. If they are *sincere* in their detraction, it is their *ignorance* which prompts it—and arrogant ignorance *deserves* no charity:—if they are *not* sincere, and *think* different from what they *say*, then they are *hypocrites*, and of the worst kind, too, for they serve as false lights that may lead others astray. If, however, in most cases, these persons had *ability* and *honesty* in the proportion that they have *arrogance* and *bigotry*, they might commend what they now denounce;—but, happily for the cause of agricultural improvement, the influence of such individuals can constitute no very serious impediment to its progress—for, what is *truth*, will *prove* itself so, and must ultimately triumph.

I have been led to these remarks, Mr. Editor, by a fact recorded in your last paper, which seems to me forcibly to illustrate the advantage which may yet be derived from the application of science to agriculture. I allude to the statement in the article headed "Skilful Agriculture and Horticulture," that Mr. Pell, of Ulster county, N. Y., had, by the application of charcoal to his land, raised upwards of *seventy-eight bushels of wheat to the acre*—a crop, I believe, unprecedented in this country. It is stated upon good authority, that the wheat-growers of France have succeeded in doubling the product of wheat in that kingdom within the last ten years, chiefly through the agency of charcoal.

Now, who discovered the value of this important agent in effecting such results? Was it the conception of any of that class just alluded to, who distrust science because its application to agriculture is *new*, or who ridicule it out of pure ignorance and bigotry, or to cater for the gratification of deep-rooted prejudice and sapient self-conceit? Was it the discovery of any of the family of *Know-enoughs*—the frothy declaimers against "book-farming," who are satisfied with knowing as much as their fathers knew, and *glory in knowing no more?* No—no. Agriculture is indebted to *Science* for this important discovery. It was the suggestion of French chemists that led the wheat-growers of France to adopt the use of charcoal on their fields—and the acquaintance with this fact and the theory, no doubt, that led Mr. Pell, also, to use it for the same purpose, and with such signal success.

To whom are we indebted for the great advantage which has accrued to our farmers from the knowledge of a remedy for sour soils, and of the valuable properties of lime as an amendment to various grounds? Do we owe these discoveries to any of those boastful "practical men," who sneer at science and the learning of books? No:—this, too, is to be charged to the credit of *science*.

Such facts as these—*these alone*, indeed—are sufficient to confound with shame the shallow detractors of *science* as an aid to the farmer—and until *they* can originate discoveries by their boasted "practical experience," as important as these, they will better act the part of wisdom in holding their speech, than in betraying their stupidity in senseless slurs at that which is above their comprehension or too exalted to suit their grovelling inclinations.

Very truly, yours, D.

Experiments in raising Potatoes.—Farmers who are fond of experiments, can try the following, in the matter of raising potatoes, without much trouble or expense: Mr. Elisha Williams, of Argyle, Penobscot county, Maine, took a small quantity of potatoes last spring, and divided each potatoe into four equal parts, planting the butt ends, the seed end, and the two centre pieces separate, and the produce was, from the butt ends, 40 lbs.; from the seed ends, 60 lbs.; and from the centre pieces both together 160 lbs.—showing the superiority of the centre pieces by 58 pounds, in the quantity planted.

To Select a Good Husband.—Let the man of your choice be one who is punctual in his promises, and is industrious, sober and frugal. He should not smoke cigars, read "fashionable" books, or visit balls and theatres. Let him be dignified and have common sense, and all is well.

Tenn. Agriculturist.

From the Southern Planter.

CORN.

Sir—In the November number of your work, you state that you have been informed that I had raised one hundred bushels of corn from an acre of land, and you desire me to furnish you with the mode of cultivation, &c., and I proceed to answer your inquiries; but being very much occupied, and at the same time very unwell, you must excuse me if the details are not as full and interesting as you would expect.

I have been a cultivator of the corn crop for fifteen years, and during that time have never failed, I believe, to make such crops as attracted much attention; yet, I have always thought, that on our rich lands are made too much stalk and too little corn, and have annually complained of my overseers for not planting my corn thick enough.

This year, I determined to make an experiment of my own, uninfluenced by the advice of overseer or friends, several of whom remonstrated against the extravagance of my proposition. For this purpose I selected a lot, which I considered very good land, though not of the first order, as it had no previous preparation for the purpose, having been indifferently used for many years, as a horse lot, watermelon patch, cabbage patch, turnep patch, and sometimes cultivated in corn: about one-third of it, it is true, was used a part of the preceding fall for a short time as a cowpen—which, by the bye, I have always had reason to believe, was perhaps the best possible mode of improving land that can be adopted, to the extent that it can be carried: upon the balance of the lot, I had my stacks of top fodder. In the month of May, I had this land ploughed as deep as a large two-horse plough could turn it, and after having it harrowed perfectly level and fine, I had rows opened with a coulter two feet apart, and on the 18th of May, the corn was planted at the distance of nine inches in these rows of two feet. A simple arithmetical calculation will show that this would give you 105 rows and 280 stalks in a row, which would make 29,400 stalks to the acre; and if each stalk would bring one good ear, estimating five hundred ears to the barrel, which, with large corn, is an ample allowance, the product would be fifty-nine barrels and three bushels to the acre. Well, that I had no expectation of making, to be sure; yet, I thought, that by making every allowance for those stalks that would make no corn, there must still be a much larger yield, (if it made anything,) than we had been accustomed to.

It has been my habit for many years, never to plant corn without first soaking it well, and then rolling it in plaster and ashes, a practice that I recommend with great confidence to your readers, as it not only gives the corn an early start, but preserves its color even in the dryest seasons. In this case, however, the corn was soaked and then rolled as usual, and then left until the land was ready to receive it, which, being a few days later than I had contemplated, occasioned it all to sprout; when it was brought out to be planted, I found the sprouts generally from one half to an inch in length. I was at first doubtful whether I should plant it or not; at length, I concluded, as the whole affair was but an experiment, I would let that go along with it as another experiment, that might lead to some practical result, intending to examine it on the second or third day, and if I found it dead to replant it. It was planted on Friday evening; on the following Monday I examined it, and was surprised to find the corn ready to shoot out of the earth, and in many instances it had protruded; on the next day, (Tuesday,) it might be seen from one end of the row to the other.

When the corn was about eighteen inches high, I made a parcel of children about the house, under my own superintendence, drop about a tea-spoonful of plaster in the bud of each stalk, through about half the field; but I was never able to see any advantage resulted from it, which might perhaps be owing to the fact, that in rolling and laying in the plaster, the grain itself had absorbed as much as was necessary for the roots; for many have derived great advantage from this mode of administering the plaster, when it has not been rolled. When the corn reached the height of about two feet, I ran the coulter very deep and close to the corn on each side. I then ran what we call a skimmer between the rows, and had the earth thus loosened, pulled with the hoes about the stalks as well as I could, in order to give some support to the corn, in the form of a hill. From this time the corn was never worked or touched; it grew off so rapidly as in a short time to shade the whole surface of the field, so as to preserve the moisture, and at the same time to check the growth of grass and weeds; and at the time of gathering, it was the only part of my corn land not covered with crab grass; but on that there was not a spire.

The fodder was pulled at the usual time, which was an enormous yield, though I did not have it weighed: the tops were also cut as usual, and then I invited several gentlemen to come and see the corn gathered and measured. Four of them came, to wit: Mr. Peter W. Grubbs, Mr. Fendall Griffin, Dr. Miles George, and Mr. Samuel Perrin. Two of these gentlemen first measured the land accurately, which was less than an acre: the corn was then gathered, shucked, and measured in their presence, which yielded, as you have heard, one hundred bushels to the acre. I have never obtained a certificate of the facts from these gentlemen, as it was not my purpose to make any parade in the papers about it, (though I confess I think it the duty of every farmer to give to his brother farmers the results of such experiments, whether successful or otherwise,) and as you will probably have an opportunity of seeing them, or most of them, before I shall, I wish you would obtain it, and publish it in connection with this communication.

It should be remembered that the season was what would generally be called a good one. There was an abundance of rain, but it did not fall in such proportions, or at such times, as I thought best calculated to advance the crop; there were only two days, however, throughout the season, (and that at a critical stage,) that it showed signs of suffering from drought, but of course it *did* suffer for some days before it began to give way.

Thus far, I have dealt in facts; but if you will bear with me a little while, as I have pen in hand, I will now indulge a little in speculation. The result of this experiment has served to satisfy me, that it is practicable to make one hundred and fifty bushels to the acre on our best corn lands, properly prepared, and with a good season—though with a very dry season, it might bring very little. In the first place, I am convinced that this lot would have yielded me much more than it did, if it had been planted with any other kind of corn than that which was planted. Some two or three years ago, I was persuaded by my neighbor, Burton, who was a good practical farmer, to try what is generally known in that neighborhood as "Gooch's corn," which he represented as remarkable for producing regularly two ears to the stalk on common land—which my experience has taught me is a quality peculiar to that description of corn, and will, for that reason, answer a good purpose on very poor land; but it is the most indifferent corn in use for good land—for on the *best land*, I have never been able to get more than the same two short ears, measuring about eight inches in length—and for this it must have proper room, while, with the large eared gourd-seed corn on land of the same quality, the yield has been more than double. By some mistake or negligence on the part of my overseer, who prepared the corn for planting, this was the corn selected, although I had determined never to plant another grain of it on any quality of land that I had. This was the only piece of corn I had of that description.

Again, the ears made were small, generally of the size of the Baden corn, which, when I tried it, usually took 900 ears to make a barrel—and, estimating 900 of these ears to the barrel, it would show that there were 18,000 stalks that produced, on an average, though some of the stalks had two ears; and, by the calculation before made, there were 11,400 stalks that did not produce, which no doubt diminished, in a great degree, the product of the balance, as they served not only to draw heavily on the soil, but to crowd and prevent the free circulation of air. Now, if these 11,400 stalks are taken out, and the remaining 18,000 are properly distributed, they would produce much larger if not a greater number of ears—so that, by planting in rows three feet apart, at the distance of ten inches, it would give you 17,640 hills or stalks of corn, at which distance it must be obvious from the experiment already made, that every stalk would bear, (for in that case, the same number did bear, when crowded up with 11,400 that did not bear,) a full ear: then estimating 600 ears to the barrel, which would be ample, and you would have 29 barrels and two-thirds of a barrel; which, with the extra ears, (for many of the stalks would produce two,) would overrun the thirty barrels.

At all events, this is the experiment I mean to make next year; and from it, with a good season, I anticipate 150 bushels of corn—and I wish this communication may have the effect of inducing others to try it, if it is only upon a quarter of an acre. I have already laid off my lot, and am preparing it for the trial.

Yours, &c., John M. Botts.

Washington, Dec. 27, 1843.

We have not been able to comply with Mr. Botts' request, by obtaining the certificate he alludes to, because we have seen only *two* of the gentlemen; but they corroborate his statement to the fullest extent—that is as good as if a thousand had certified to it.—Ed.

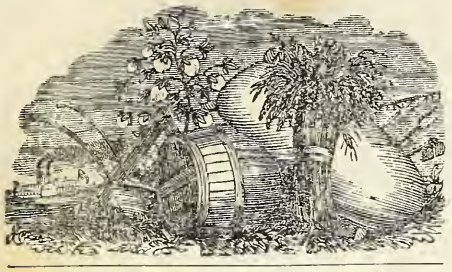
From the *Albany Cultivator.*

NECESSITY OF MANURING.

It is obvious that the manuring of a farm should only be limited by the ability of the owner. On a plentiful supply of manures, is depending the fertility of his soils, the amount of his crops, and consequently the extent to which his labor is rewarded. There is no expenditure on a farm, so safe as that for manure; and the labor required to increase it, is never labor lost; at least, if directed by an ordinary share of agricultural knowledge and skill. Every source of supply should be made available; nothing capable of fertilizing should be lost. The farmer who takes from his soil more than he returns to it, is surely impoverishing it; and if he escapes such a calamity himself, he leaves to his successors a worn-out farm. If he returns as much as he receives, his farm will retain its original fertility only; but the true farmer will scarcely be content with this. To *increase* its fertility, and the amount and quality of the crop taken from the soil, should be the aim of the husbandman. This done, his labor is lessened, his profits are greater, his farm is worth more; nor must the *pleasure* arising from beautiful fields, golden harvests, fine animals, accumulating prosperity, be omitted in making up our estimate of the advantages of successful culture.

Manure may be a homely subject, but on its preparation and use every thing is depending. Without it, the deep green of our pastures, the golden yellow of our corn-fields, and the fine beef and white loaf of our tables, could not exist. To the farmer, manure must be the first thing, and it must be the last thing: with it, he can do every thing—without it, nothing.

Farmers, make your own Candles.—Take 2 lbs. of alum, for every 10 lbs. of tallow, dissolve it in water before the tallow is put in, and then melt the tallow in the alum water with frequent stirring, and it will clarify and harden the tallow so as to make a most beautiful article for either winter or summer use, almost as good as sperm.



WEDNESDAY, MARCH 6, 1844.

THE BACK VOLUME.

All new subscribers who may desire it, can obtain the first volume, neatly bound in boards, at one dollar the volume.

Culture of Corn.—As this is the season for planting this most valuable crop, in the absence of original communications on the subject, we have transferred to our columns the first part of the Prize Essay of Mr. Williams, read before an Agricultural Society in Kentucky, and shall conclude it in our next,—to which we invite the reader's attention. Although this Essay is particularly adapted to the culture and climate of Kentucky, yet it will be found to contain much valuable information to planters in every section, where corn is cultivated.

The first and most important consideration to every planter, in the culture of any thing and every thing, is the proper application of manure —a subject in which the investigations of science are every day making new and important discoveries. It therefore behooves every planter, who desires to pursue a profitable system of Agriculture, to investigate thoroughly this important branch of his pursuit—make himself familiar with the properties and relative values of the different manures, and the manner of their application to his soils and crops; and then it behooves him to adopt that system of culture which the experience of enlightened men has established, as best adapted to each particular soil, climate and production.

It will not do for men, in this age of enlightened, scientific agriculture, to assert, that because they have devoted their whole lives to the practical operations of farming, they cannot, in middle age, or even at a more advanced period of life, be taught something new. Such an opinion, if entertained by any, and we know it is held by some, is very absurd. As well might that man, who could not read or write, but who had nevertheless kept his mind constantly employed in the contemplation of some particular branch of science, say that he could not be taught by one whose acquirements had enabled him, through a long course of investigation and scientific research, to comprehend it fully in all its details.

It is but recently, in this country, that the aid of science has been sought in the pursuit of agriculture. Why, then, may it not accomplish, in this important branch of industry, triumphs equally great, as all admit it has performed, in mechanics? Has it not a wider field for the display of its extraordinary powers in the accomplishment of good? Most assuredly. Why, then, we ask, shall the Agriculturist reject the benefits of its teachings in this particular branch of industry, while he so readily acquiesces in its utility in every other department?

But, we have been led into a train of thought which we did not contemplate. Our object was simply to direct the reader's attention to the Essay of Mr. Williams.

Corn Stalk Sugar.—A friend in Walton county, has afforded us the following information in reference to the relative value of early and late Corn, for the purposes of making Sugar, which may be advantageous to those who are disposed to make the experiment of making Sugar from Corn-stalks. Although this subject has attracted much attention throughout the country, for the last two years, it is not yet sufficiently tested to establish the practicability of making it a profitable business. It is, however, yet in its infancy; and as the experiments already made have gone far to convince many of its utility, it is impossible to form any idea of the improvements which time and experience, aided by science, may accomplish in this branch of industry. We hope, therefore, that our planters will continue to make experiments until they have fully satisfied themselves of its utility.

I have known, for many years past, that the stalks of *late planted* corn contain at least twice as much saccharine as those of early planting—and have wondered that persons raising corn for the purpose of making sugar, had not observed the fact. Corn, to make sugar, should not be planted in the lower part of Georgia, before about the first of July or as late as it will bear planting, in order to come to maturity before the frost will injure it. Corn, in the upper parts of the State, and further North, might be planted in June. In the early settling of some of the middle counties of Georgia, we often had to plant our ground in corn, after cutting off the wheat on account of the scarcity of open land: I then discovered that the stalks of this late planted corn contained almost as much saccharine as the sugar cane—and I have frequently observed the same fact since with late planted corn. Let those who intend experimenting on cornstalk sugar, try the plan of late planting, and they will see a surprising difference in the sweetness of the stalks.

CORN COBS.

We extract the following from a communication in the Central N. Y. Farmer, by C. N. Bement, Esq.;

"We will take the present opportunity of directing the attention of our readers to the great value of meal obtained by grinding corn and cob together for stock: and from the many evidences of practical farmers, as well as from experiments of our own, we cannot but press it upon the attention of the prudent farmer. Many will object to this on account of the low price at which corn and oats are selling. But we see no reason why a farmer should throw away or squander his feed, because it sells at a low price. We conceive that one of the very best reasons why he should economise in every possible manner, so that he can have more to sell, and the extra quantity make up the deficiency in price.

That there is a nutritious substance in the cob, no one, we think, that has paid any attention to the subject, will pretend to deny. In throwing away the cobs of our corn, we have been wasting very good feed. On distillation of four gallons of cob meal, four gallons of spirits have been obtained, and other nutritive matter besides saccharine, such as mucilage and oils, has been found in it. 'But besides the actual economy,' says a writer in the American Farmer, 'there is another advantage in this way of feeding corn, which ought to engage the attention of every farmer. It is notoriously true, that the unground grain of corn is heating to the stomach of all animals, and of difficult digestion, producing cholic and other inflammatory disorders, particularly in horses. They are deprived of the benefits derived from the stimulus of distension. (so necessary to the health of all animals,) by being unable to eat a sufficient bulk to produce it, before they become gorged.'

For hogs, corn and cob meal is much improved by scalding, and by boiling with vegetables of any kind, and still more by a partial fermentation.

The manner of feeding stock on raw or unground corn, is too common. It is undoubtedly one of the best of grains to finish off a lot of stock; but it lacks bulk, and is too stimulating without some coarser or more bulky substance to mix with it. Corn alone gives too much fat inside, without a corresponding bulk of flesh outside. It has been found that corn and oats, equally mixed and ground together, will improve and fatten hogs faster than the same amount of corn alone.

HINTS TO FARMERS.

Great profits in agriculture can result only from great improvements of the soil.

Great improvements of the soil can result only from unremitting industry.

The chief study of every farmer *should be what is useful, and what is useless expense, in relation to his art.* The discrimination between these is the master key of the farmer's prosperity. The first should be incurred with a freedom little short of profusion. The last should be shunned, as the sailor shuns the rocks, where are seen the wreck of the hopes of preceeding mariners.

Liberality in providing utensils, is the saving of both time and labor. The more perfect his instruments, the more profitable are they.

So also is it with his working cattle and his stock. The most perfect in their kinds are ever the most profitable.

Liberality, in good barns and warm shelters, is the source of health, strength, and comfort to animals; causes them to thrive on less food, and secures from damage all sorts of crops.

Liberality also, in the provision of food for domestic animals, is the source of flesh, muscle and manure.

Liberality to the earth, in seed, culture and compost, is the source of its bounty.

Thus it is in agriculture, as in every part of creation; a wise and Paternal Providence has inseparably connected our duty with our happiness.

In cultivating the earth, the condition of man's success is his industry upon it.

In raising domestic animals, the condition of his success is, kindness and benevolence to them.

In making the productiveness of the earth depend upon the diligence and wisdom of the cultivator, the Universal Father has inseparably connected the fertility of his creation with the strongest intellectual inducements and the highest moral motives.

In putting the brutal world under his dominion, he has placed the happiness of which their nature is susceptible, under the strong guarantee of man's interest.

Instead, therefore, of repining at his lot, let the cultivator of the ground consider his as among the highest and happiest of all human destinies, since in relation to the earth he is the instrument of Heaven's bounty; and in relation to the inferior orders of creation, the almoner of Providence.

A beautiful Oriental proverb runs thus:—"With time and patience, the mulberry leaf becomes satin."

MANURES.

While attention is demanded to every branch of the farming interest—there is one that should always receive special attention. The manure heaps should be attended to at all times; and neglect in this particular, will certainly result in a great diminution of the products of the farm. There are many of our farmers, who give little or no attention to the matter, although every agricultural journal in the country is urging the subject upon them. As well might a man expect to secure a full and perfect development of the human system, without proper food and nourishment, as for a farmer to expect a bountiful harvest, without providing the proper food and aliment for his crops.

It is not uncommon when accounts are published of extraordinary yields of grain, that expressions are heard, "these are fancy crops," "on paper," &c. Why is this? Simply because the farmer, who has been content to exhaust his soil, until his crops are of the most meagre description, has never witnessed any such yield as is spoken of—and he concludes that he has done about as well as any one could upon his farm. It matters not that the statements are verified by disinterested persons—crops actually measured, as taken from the land—his incredulity remains. If you can persuade the individual, however, to commence himself a judicious system of manuring, it will not be long before he begins to inquire as to the difference in the appearance of his crops. As successive seasons roll round, he finds that the *farmer's mine*, after all, consists in a well prepared manure heap, skilfully applied to his land.

It is not our design, at present, to enter into an examination of the different kinds of manure, or which of them is best adapted to the various purposes of the farmer. It may doubtless be shown, that the foundation upon which the farmer is mainly to rely, is the manure heap of his own yard. This can be increased with a little care and attention, to a very great extent. The value, also, of green crops as a manure, is not generally appreciated. Where there is a deficiency of the common barn-yard manures, the most economical substitute is that derived from urning in green crops. This practice now prevails to a very considerable extent in the wheat growing districts, at the west, and has produced a very great change within the last few years—more abundant crops are now realized, and the land is preserved in good tilth.

It is of the utmost importance to the farmer, to keep his land improving. Industry and attention alone will secure this. If he neglects manuring, for a single season, his lands show the neglect, and a longer time is required to bring his farm into good condition. We would urge upon the farmer, to be awake at all times to the preparation of manure. Let nothing be lost or wasted. Let the barn-yards and stables be prepared, so as to secure, in the most perfect manner, all the litter and droppings, and urine from the cattle—and as occasion may require, let swamp earth and lime be mixed with the barn-yard manure.

Not long since, in visiting one of our dairymen, in a northern town, who stables about fifty cows, we were very much gratified to find so much attention given to the securing, and preparing for his farm, the manure from his stable. Nothing seemed to be wasted. The construction of his stables for his cattle was such as to secure the whole. From the product of his farm, the last year, it is very evident that attention has heretofore been given to the subject, in some measure proportioned to its importance.

It is our intention to resume this subject hereafter, and to examine the various qualities, and advantages of the different kinds of manures, that are used in this country.

Central New York Farmer.

From the Southern Miscellany.

THE SWEET POTATO,

MR. HANLEITER—In one of the numbers of the "Miscellany," published about a year ago, I saw an article, (copid from the "Southern Cultivator,) on the culture of Sweet Potatoes, from the pen of Mr. McKinly, of Oglethorpe county, which seemed to me to point out the best mode of raising that article, and I resolved to test the plan by experiment. Accordingly, early in the season, I prepared my ground by deep and thorough ploughing, and continued at every suitable opportunity to plough it until the season should suit for transplanting my slips. This did not occur until about the tenth of June—at which time I set them out. The mode which I adopted was as follows: I first laid off my ground by running furrows with a long wide shovel four feet apart—then followed each furrow with a long scooter, and that by a long coulter. This done, a furrow on either side of the one laid off was run in the same way—first the shovel, then the scooter, then the coulter. The bed so prepared, I smoothed off with a hoe, leaving it flat on top, and but slightly elevated above the surrounding surface. In the centre of this, fifteen inches apart, I planted my slips. They grew off remarkably well, scarcely one dying.

The cultivation was such as I gave my corn—only there was but two ploughings and two hoeings—and I was careful that not a vine should be covered up, or broken off.

The soil in which they were planted was light and sandy—not rich—and the yield, one hundred and seventy bushels from 66-100 of an acre. The potatoes were Yams, of the ordinary kind—and such as I had cultivated in the old way for several years, and were, on the average, doubly as large as any I had ever raised before. The yield from the same quality of land was nearly double.

They were dug soon after the first frosts, when the vines were partially killed and the ground dry, when I found the soil in which they grew, as light and mellow as the day they were planted. I put them up in a house, prepared for the purpose, under my dwelling, covering them entirely with dry sand—and none have rotted except those which were injured in digging, and those only before they were housed. I am so much pleased with my success last year, that I shall try the same plan again this—being careful, as I was then, to select the largest potatoes for seed, believing that potatoes, as well as every other plant, must degenerate so long as the smallest and most inferior seed is used in planting. I send you a specimen of what my potatoes are now, of the excellence of which you can judge by tasting.

Yours, truly, E. L. WITTICH.

Madison, Feb. 29th, 1844.

AUGUSTA MARKET.

TUESDAY P. M., March 5.

Cotton.—We have no new feature to notice in our market, which seems to be gradually declining. Few persons seem willing to operate, and the few sales made are forced upon the market. There has been so little done, that we omit quotations.

TO HOG RAISERS.

THE subscriber offers for sale the JERUSALEM ARTICHOKE, which, by early application, can be obtained at his Store in Monroe, Walton county. The value of this article as food for Hogs, is no longer a matter of experiment or doubt. It has been fairly tested in Kentucky and Tennessee, and the Northwestern part of Georgia. They are required to be planted in the spring, and will be fit to feed in the ensuing fall and winter. I hazard nothing when I say not one-tenth of the corn now fed to hogs, is at all necessary; and, by the use of the artichoke, the use of corn, for hogs, may be entirely dispensed with through the whole winter. The first year, they are no more trouble than sweet potatoes: after that, they require no cultivation.

LINNÆAN BOTANIC GARDEN
AND NURSERY—LATE PRINCE'S,

Flushing, L. I., near New York.

THE new DESCRIPTIVE CATALOGUE, not only of FRUIT, but also of ORNAMENTAL TREES, SHRUBS, and PLANTS, cultivated and for sale at this ancient and celebrated Nursery, (*known as* PRINCE'S, *and by the above title for nearly fifty years.*)

WITH DIRECTIONS FOR THEIR CULTURE, may be had *gratis* on application to the New Proprietors, by mail, *post-paid.*

The collection at this establishment is unrivalled, and prices generally *very much reduced;* and the proprietors flatter themselves that the Catalogue will be found to surpass in extent of information and usefulness, any thing of the kind ever before presented to the public; and to be worthy of a permanent place in the library of the Horticulturist. ORDERS will be promptly executed. WINTER & CO.,

Flushing, February 17, 1844. Proprietors.

TURNEP SEED.

A SUPPLY of the following varieties of fresh TURNEP SEED just received, viz:

Yellow Sweedish or Ruta Baga, very fine for stock,

Large Globe Turnep, } Fine
" White Flat do. } for
" Hanover or White Ruta Baga do } table
" Norfolk do. } use.

For sale in quantities to suit purchasers, by

Aug. 30 18-tf WM. HAINES, JR.

GARDEN AND FIELD SEED.

A GENERAL assortment of fresh and genuine GARDEN and FIELD SEED, among which are the following:

Red and White Clover,
Blue and Green Grass,
Rye and Orchard do.,
Timothy and Herds do.,
Millet and Lucerne do.,
Seed Corn of every valuable variety,
Seed Wheat,
Buckwheat and Potato Oats,

Kept constantly on hand by the subscriber, all of which are offered for sale at very moderate prices. All orders, by mail or otherwise, executed with neatness and despatch.

VOL. II. AUGUSTA, GA., MARCH 20, 1844. No. 6.

From the New England Farmer.

DANA'S PRIZE ESSAY ON MANURES.

SECTION SECOND.

Shovelling over the Compost Heap.

The above remarks, (section 1st,) may be called our compost heap. It must be well shovelled over. You must, reader, before you cart it out and spread it, understand well what this compost contains. Now, just let me turn over a few shovels full, and fork out the main points to which I wish to call your attention.

1st. That all plants find in stable manure every thing they want.

2d. That stable manure consists of water, coal and salts.

3d. That these, water, coal and salts, consist in all plants of certain substances, in number fourteen, which are called—1. Oxygen; 2. Hydrogen; 3. Nitrogen; 4. Carbon; 5. Sulphur; 6. Phosphorus; 7. Potash; 8. Soda; 9. Lime; 10. Magnesia; 11. Alumina or clay; 12. Iron; 13. Manganese; 14. Chlorine; which last, as we have said, forms about one-half the weight of common salt. And if you always associate with the word chlorine, the fertilizing properties of common salt, you will, perhaps, have as good an idea of this substance as a farmer need have, to understand the action of chlorine.

4th. These fourteen substances may be divided into four classes: 1st, the airy or gases, oxygen, hydrogen, nitrogen and chlorine. 2d, the combustibles, carbon, sulphur and phosphorus. 3d, the earths and metals, lime, clay, magnesia, iron and manganese. 4th, the alkalies, potash and soda.

You may be surprised that I have not turned up ammonia, but this exists in plants as hydrogen and nitrogen.

5th. The term salt includes a vast variety of substances, formed of alkalies, earths and metals, combined with acids. Fix well the meaning of this term in your mind, and remember the distinction pointed out, that some salts are volatile, and act quick in manure, and others are fixed and act slower.

6th When plants die or decay, they return to the earth or air these fourteen substances.—Those returned to the earth from mould, which thus is composed of carbon, salts and water, is natural manure.

7th. Mould consists of two kinds, one of which may be, and the other cannot be, dissolved by water. Alkalies put it into a state to be dissolved, and in proportion as it is dissolved it becomes valuable as a manure.

8th. If then manure contains only water, carbon and salts, any substance which affords similar products, may be substituted for it. Hence, we come to a division of manures into natural and artificial. The consideration of these is the carting out and spreading of our compost. And we shall first consider in detail the natural manures. That is, those which are furnished us by the dung and urine of animals, and the manure or mould formed by the decay of animal bodies or plants. These are truly the natural manures, consisting of water, mould and salts. This is all that is found in cattle dung. This being premised, we may divide manures, reader, for your more convenient consideration, not by their origin, but by their composition. We may divide manures into these three classes: First, those consisting of vegetable or animal matter, called mould: Secondly, those consisting chiefly of salts: and, thirdly, those consisting of a mixture of these two classes. And, beginning with the last first, we will now proceed to their consideration.

SECTION THIRD.

Carting out and Spreading.

The general chemical information set forth in the preceding section, will be of no service to you, reader, if it conducts you not beyond the result arrived at in the close of the last section, that cattle dung is composed of water, mould and salts.

You want to know what salts, and how they act. If you understand this, you may be able to say beforehand, whether other things, supposing their nature understood, can take the place of the mould and salts.

The mould, then, of cattle dung, as all other mould, contains the following substances:

The water consists of oxygen and hydrogen.

The mould consists of carbon, oxygen, hydrogen, nitrogen and ammonia.

Thus it is seen that the mould contains all the substances found in the first class into which the elements of plants were divided. The salts contain the sulphur, phosphorus, and the carbon, as sulphuric, phosphoric, and carbonic acids, and the chlorine as muriatic acid or spirits of salt.

The acids formed of the elements of the fourth class of the substances entering into plants, are combined with those of the second and third classes, namely: the potash, soda, lime, clay, magnesia, iron, and manganese. Here, then, we have all the elements of plants, found in cattle dung. Let us detail their several proportions. We have all that plants need, distributed in cattle dung, as follows:

In 100 lbs. of cattle dung, are,	
Water,	83.60
Mould, composed of hay,	14.10
Bile and slime,	1.275
Albumen, a substance like the white of an egg,	175
Salts, silica, or sand,	14
Potash, united to oil of vitriol, forming a salt,	05
Potash, united to acid of mould,	07
Common salt,	08
Bone dust, or phosphate of lime,	23
Plaster of Paris,	12
Chalk, or carbonate of lime,	12
Magnesia, iron, manganese, clay, united to the several acids above,	14
	100

SECTION FOURTH.

Of the Action of Mould in Cattle Dung.

Here, then, we have cattle dung, with its several ingredients, spread out before us.

We have now to study its action. We need here consider only the salts and mould. The water is only water, and has no other action than water. The mould includes the hay; for that has, by chewing, and the action of the beast's stomach, lost so much of its character, that, mingled with the slime and bile, &c., it more rapidly decays than fresh hay would, placed in similar circumstances. During this act of decay, as you have already learned, the volatile parts of the mould are given off in part. These escape as in burning wood, as water or steam, carbonic acid, and ammonia. In consequence of this slow mouldering fire or decay, the manure heats. Here, then, we have three very decided and important actions produced by the vegetable part, or mould of cattle dung. First, carbonic acid is given off; second, ammonia is formed; third, heat is produced. Let us now consider each of these, and their effects.

First, the great action of the carbonic acid is upon the soil, its earthy parts. It has the same action on these, that air, rain, frost, have; it divides and reduces them. It not only reduces them to powder, but it extracts from the earth potash and the alkalies. This is a very important act, and shows why it is necessary that decay or fermentation should take place in and under the soil among sprouting seeds and growing roots, in order that they may obtain from the soil the salts they want.

If well-rotted manure contains abundance of these salts, ready formed in its mould, then there will be less necessity of this action of carbonic acid. But here again it must be remembered, that this abundance of salts, ready formed in mould, can be produced only at the expense of great loss by fermentation of real valuable parts. For,

Secondly, the next great action of the mould of cattle dung, is to produce or form ammonia. This plays a threefold part: its first action is to render the mould more soluble; this action it possesses in common with the fixed alkalies, potash and soda. All the alkalies put a large, but undefined portion of mould, into a state fit to become food for plants. The second action of ammonia is this, it hastens decay. It is the bellows, we may say, kindling the slow mouldering fire. The third action of ammonia is to combine with any free acids, such as vinegar, or even an acid formed of mould itself, but especially with aquafortis, or nitric acid, which is always produced where animal or vegetable matters decay. This is a highly important fact. The result of this action, the production of ammonia and aquafortis during the formation of mould, is, that a kind of saltpetre is thereby produced. That is, the ammonia and aquafortis unite, and form a salt, with properties similar to saltpetre. But we want the first and second action of ammonia to occur, before the third takes place. Consider now, reader, whether a more beautiful and effectual way can be devised to hasten decay, and render mould more fit for nourishing plants, than this which nature has provided. The ammonia is volatile. It remains, not like potash and soda, where it is put, incapable of moving unless dissolved by water; but ammonia, like steam, pervades every part. It is as expansive as steam. Heated up by the slow mouldering fire of decay, it penetrates the whole mass of mould. It does its work there. What is that work? It has already been told. But, if it finds no acid to combine with, it then unites with the mould itself. It is absorbed by it. The mould holds it fast; it stores it up against the time when growing plants may need it. Now it is only where the abundance of ammonia produced satisfies these actions of hastening decay, making mould soluble, and filling its pores without combining with it, that the formation of saltpetre takes place. So where animal matters, which are the

great source of ammonia, decay, there we may expect all these actions to occur.

How important, then, is that action of mouldering which produces ammonia. If, reader, you will reflect upon the consequences of this action, you will at once see, that if the mould is in too small a quantity to retain the ammonia, it may escape. If, by a wasty exposure, you allow your mould to dissipate itself in air, as it certainly will, you not only incur the loss of that part of the mould, but you diminish, at the same time, the chance of keeping the ammonia which has been formed. No doubt all cattle dung exposed to air, forms more ammonia than it can retain. Hence the necessity and the reason of forming composts with this substance. "Keep what you have got, and catch what you can," must never be lost sight of in manure.

The third action of mould is, the production of heat. Little need be said upon this. That a slight degree of heat hastens the sprouting of seeds, you well know. That different manures produce different degrees of heat; that some are hot, some cold, you well know, and adapt your seed and manure to each other. The degree of heat depends upon the rapidity with which decay occurs. And this is affected by the quantity of ammonia which each manure can afford. The great point to which your attention should be directed, when considering the power of mouldering to produce heat, is, that it shall not go so far as to burn up your manure, just as hay will heat and take fire.

(To be continued.)

From the Western Citizen.

PREMIUM ESSAY ON THE CULTIVATION OF CORN.

BY GEORGE W. WILLIAMS.

(Concluded.)

11. The crop is to be secured by severing the stalk near the ground, and by stacking it in the field. If the grain is for bread, it should not be cut till after the first frost, or until after it has fully matured. Corn intended for stock, may be cut at an earlier period. As soon as the milk is entirely out of the grain, and it has received its enamel, or has a firm feel to the nail, the work may be begun. Sixteen hills, from a square, are to be put into each stack, and the stacks are to be made as follows: In the first place, ties are to be made to support the stacks, at least ten days before the cutting is commenced. The laborer counts eight rows from the edge of the field, passes between the eighth and ninth rows, ties the eighth and ninth hills in each of these rows, by bending the stalk diagonally across the square, and twisting the tops securely together. These ties being made previous to cutting, become staunch and afford good stays for stacks when set up. In cutting, the workman has a straight knife, which is best made from an old scythe blade. With a straight knife, he can strike in any direction, and it is necessary for him to do so, because from the many positions in which he will find the stalks standing and leaning, and sometimes lying, he will have to make many different kind of strokes which cannot be done so well with a crooked knife as with a straight one. In this work, he goes first to the tie; here he cuts around the tie and places the hills as he cuts them carefully and nearly erect within the tie. He then cuts with the right hand, gathering the corn with his left, and sustaining the stalks, when cut, upon his left arm. More than one hill may be cut, and sustained in this way, before he carries them to the stack. In carrying them to the stack, he does not put them on his shoulder, nor does he drop his knife. It is held in the right hand, and the turn of corn is carried to the stack upon the left arm. He places it carefully on the stack, equalizing each side and trimming the stalks properly to the stack. The chief difficulty in stacking is to keep the stack from going into a twist, and this can be done only by attention in placing the stalks in such a way as that they, while they recline to the head of the stack at the top, shall not lean either to the one side or the other. This mode of cutting and stacking is the most expeditious one known to me, but to work upon this plan, the laborer must be a strong man and an active one. In average crops, when the stalks stand straight, such a man can put up twenty or twenty-five stacks in a day. But this is extra work, and in such corn I consider sixteen stacks a day's work for a common hand. Another, and the most usual mode of cutting and stacking, is to approach the tie and cut around it as in the first instance, placing the stalks as cut within the tie. When this is done, the whole square is cut and laid in bunches of four hills upon the ground and across the rows. The knife is then thrown down, and the bunches carried to the stack. This each man may do in the way easiest for himself, but experience will teach all, that the easiest and most rapid is never to put the turn on the shoulder, but carry it on the arm. Too much care cannot be taken in making the stack, for if it gets into a twist, more than half the corn and fodder will be destroyed.

12. When the corn is thus secured, and after the corn has sufficiently dried, the next operation will be to crib that part of it which is for bread, and take care of the fodder. This must be done before the winter sets in, for shucking corn in winter weather is disagreeable work, and but little can be done at it. Damp weather should be selected, if possible, and the laborer will place himself at the stalk, and as he takes the ears from the shuck and stalk, he casts them in a compact heap, and places the fodder in two or three piles around the place where the stack stood. When this is done, the tie having been left standing, he places the fodder around the tie again, making a compact stack, pressing the whole together well. A band must be put around the top of the stack. In doing this, the butt ends of three or four stalks are to be inserted a foot or more into the body of the stack near the top, and the stalks bent around the stack; at the tassel end of this band, another bunch of stalks is to be inserted as before—around this, the tassel end of the first bunch is to be wrapped, and so on till the band passes altogether around and binds the stack well. The stacks tie best in the morning, when the dew or damps of the night are on the fodder. The corn is then carted to the crib. That part of the crop intended for stock is left in the field, from whence, at the proper time, it is carried to the place of feeding, and there consumed, fodder and all.

13. I have thus given the whole process in the cultivation of corn, and, as I think, the best method to secure a good average crop upon average soil. I have, however, an opinion that upon prime land, with a judicious use of manures, much larger crops may be grown. I am now engaged in making the fourth experiment to test the truth of this opinion. These experiments have not been entirely satisfactory to myself, but as I intend to continue them, I may be enabled, hereafter, to arrive at a mode of cultivation to be preferred to the one now practised. Indeed, I am sure, from what I have done, that as much as one hundred and fifty bushels per acre, one year with another, with great care in cultivation, if the land is first rate, can be attained. But the soil must be the best for corn, and entirely free from weeds. My plan has been, in these experiments, to plow deep and pulverize the soil thoroughly before planting—to plant early and close—to put one stalk in a place two feet by eighteen inches apart, except in the last experiment, when I put two stalks in a hill two feet apart. The whole after cultivation was done with the hoe, and was comparatively of a light character. The first experiment I made produced the largest yield—all the circumstances were favorable. The other three had several difficulties to encounter, most of which, except in the second, when a severe drought at the time the grains were filling, nearly cut off the whole crop, might have been to some extent obviated. The average of the four crops is one hundred and ten bushels, four gallons one and one-half pints, per acre. This falls greatly short of 150 bushels per acre, but I am confident that so large an average crop as that may be attained on choice land, with proper attention.

GEO. W. WILLIAMS.

Near Centreville, Sept. 28, 1843.

EXPLANATION OF TERMS.

(Continued from page 28.)

Acids—are substances of a sour taste.

The acids are very numerous. Their most distinguishing properties are,

1st. They change to red those colors of vegetables which the alkalies change to green.

2d. They combine with alkalies, and thereby form various kinds of salts.

Thus, the combination of muriatic acid with soda forms common salt.

Some of the acids are met with in a solid state—others in a fluid state, as vinegar—and others in a gaseous state. Of the latter is carbonic acid, which requires a more particular description.

The carbonic acid, when uncombined with any other substance, is always met with in a state of gas, and hence it is called carbonic acid gas. It is the same substance which was formerly called fixed air. It exists in a small proportion in the atmosphere. It destroys life and extinguishes the light of a candle when immersed in it. It is disengaged largely from liquors, such as beer, cider or wine, when in the act of fermentation. It is this gas which produces the many unhappy accidents in some subterraneous caverns, in closed cellars containing large quantities of fermenting liquors, in some deep wells, and in bed chambers, warmed by burning charcoal in pans.

This acid combines with a great variety of substances, which are then called carbonates. It exists in marble, chalk and limestone, in different proportions, all of which are called carbonates of lime, and the burning of limestone is for no other purpose, but to expel the carbonic acid, which is done by heat, in which operation the limestone loses nearly half its weight.

The alkalies attract it from the atmosphere. It is present in pot and pearl ashes, from which it is disengaged by the addition of a stronger acid, as every one may have seen in throwing pearlash into cider, as some people do to drink in the morning. The acid in the cider, in uniting with the pearlash, displaces the carbonic acid, which rises in the form of gas through the liquor, producing much foam with a hissing noise, called effervescence.

43. *Atmospheric air*—or the air which surrounds this earth, is a mixture of two different kinds of air, called *oxygen* and *azote*. It likewise contains a small proportion of carbonic acid gas, a substance already described.

It is well known that no animal will live, or fire burn, without air; but it is that part of the air called oxygen which is necessary for both. It is this which supports life and combustion; and where there is no oxygen, an animal will die and a light will be extinguished as suddenly as where there is no air at all.

All this may be made plain by a very easy experiment. Take a lighted candle, put it into a candle-stick, and set it into a pail of water so deep as that the light of the candle may rise three or four inches above the surface of the water. Then take a deep tumbler, or a wide-mouthed decanter, invert it, and let it down over the candle till the brim shall dip into the water. As the candle continues burning, the water will be seen rising in the decanter till it shall be about one quarter part full, when the candle will suddenly go out. Now the reason of the water's rising in the decanter, is because the oxygen is gradually consuming by the lighted candle; and the reason that the candle goes out, is, that the oxygen at that instant is all gone, or has all been expended in the combustion. What is then left in the decanter will be the other part or kind of air called azote, and if a small animal should be introduced into this air, it would die as suddenly as if it had no air at all.

Oxygen gas, (for you must remember that every substance in the form of air is called a

gas,) is a very wonderful substance. It unites with iron, when exposed to the atmosphere, for any length of time, and converts it into rust; it unites with melted pewter or lead, and converts them into dross, or oxyde, as it is called; it unites with another kind of gas, called hydrogen, and forms water. Yes, what perhaps it may surprise you to know, water is not a simple, as most people suppose, but a compound substance, composed of oxygen and hydrogen gas. Both its decomposition and its composition are common experiments in every chemical room.

Oxygen likewise is one of the ingredients in the composition of acids, all of which are compound substances; hence, oxygen has been called the great acidifying principle. Thus, it unites with sulphur, in the act of combustion, and forms sulphuric acid, or oil of vitriol, as it was formerly called; it unites also with carbon or charcoal, when burning, and forms carbonic acid gas, already described; and hence, we see how the carbonic acid gas, which sometimes proves fatal in close shut bed-chambers, heated with burning charcoal, is produced. The oxygen in the atmosphere unites with the charcoal or carbon in burning, and thus produces this gas, so deleterious to life when breathed without a due proportion of atmospheric air mixed with it.

These four elementary substances, oxygen, hydrogen, azote and carbon, possess a very wonderful agency in nature, and every one who has any wish to look beyond the mere surface of things, cannot but be gratified in knowing more about them. We shall have further occasion to speak of these substances in the Cabinet; it is important, therefore, that the character and distinguishing properties of each should be well understood. These are given in the following concise definitions, which are not to be forgotten, viz:

49. *Oxygen*—is one of the constituent principles of water; it is called vital or respirable air, and is essential both to the support of life and combustion.

This substance performs an important part in most of the changes which take place in the mineral, vegetable, and animal kingdoms.

50. *Hydrogen*—is one of the constituent principles of water; it is very inflammable, and was formerly called inflammable air. It is the lightest of all ponderable substances.

This is the substance generally used in filling air-balloons. It is readily obtained by the decomposition of water. Vegetables and animals also in a state of decay and putrefaction afford it, and it is evolved from various mines and volcanoes.

51. *Azote*—is that part of atmospheric air which is incapable of supporting life or combustion.

All combustible substances burn violently in pure oxygen gas, and if it was not diluted in the atmosphere by a large portion of azote, it would be impossible to extinguish any considerable fire when once lighted up, and something like the general conflagration of the world would immediately commence.

Azote exists abundantly in nature, forming the greater part of the atmosphere, and is one of the principal ingredients in animal substances.

52. *Carbon*—is the pure part of charcoal.

Carbon forms a large proportion of all vegetables; it exists also in animals, but its quantity is small.

53. *Carbonic Acid*—is a combination of carbon and oxygen, in the proportions of 18 parts carbon to 82 parts oxygen.

An account of this substance has already been given under the article "Acids." It may here be added, that the sources of this acid are immense. It exists in the atmosphere; it is found in abundance in many mineral waters, as at Ballston and Saratoga, in the State of New York; it is produced by the combustion of wood and charcoal, by the fermentation of liquors, and by the decomposition or putrefaction of vegetable substances; but the largest store of it is that enormous quantity solidified or rendered solid in all the immense beds of chalk and limestone with which every part of the globe abounds.

Of limestone, 45 parts in every 100 are computed to be carbonic acid.

As before observed, when uncombined with any other substance, it always exists in the state of gas. It is heavier than atmospheric air. If this gas be poured from a wide-mouthed jar upon a lighted candle it will be as effectually extinguished as by water.

54. *Effervescence*—is a sudden disengagement of gas taking place within a liquid and separating from it with a hissing noise.

55. *Chemical Affinity*—is a term used to signify the attraction or tendency there is between the particles of certain substances, of different natures, to unite, thereby forming a third substance possessing properties altogether different from those of either of the two substances of which it is composed.

Thus, potash and oil have a tendency to unite, thereby forming soap, which is a third substance very different either from the oil or the potash, of which it is composed.

Those substances which are capable of uniting in this manner, are said to have an affinity for each other as oil and potash; but oil will not unite with water, and therefore those substances which do not form a chemical union, are said to have no affinity.

56. *The Primitive Earths*—are four, viz: clay, sand, lime and magnesia.

These are the only earths which enter into the composition of soil; they enter also in very minute portions into the organization of plants.

Sand and clay are by far the most abundant; lime is required but in small proportions; every soil, however, is defective without it. Magnesia is found but in few soils; its place is well supplied by lime; its entire absence, therefore, is not considered any defect.

(To be continued.)

From the Albany Cultivator.

INDIAN CORN.

In actual value to the country, it is probable our Indian corn crop is not exceeded by any other of our agricultural products. Adapted, in some of its varieties, to every part of the United States; exceeded in nutritive powers by few, if any, of the cultivated plants; cultivated with great ease, and only requiring one season for its perfection, it is not surprising that corn should be a general favorite, and that more land should be employed in the production of this crop, than any other one. The corn crop of the United States may safely be estimated at 400,000,000 of bushels; and its value $125,000,000 annually. Immense as is the quantity of corn produced, it must be evident to all, that this quantity might be greatly increased, even were no more land devoted to its culture, by a more skilful husbandry. It is only by this course, indeed, in the older States, that any increase of quantity is to be expected, since no considerable addition of land to that already devoted to this crop, can consistently be made. In the great valley of the Mississippi, it is impossible to set limits to the quantity that might be annually grown, should the demand induce the population to divert their productive energies into that channel.

There are few crops which show the effect of skilful cultivation more strongly than that of corn; and this marked improvement should induce the farmer, instead of adding to his number of acres in corn, to adopt that course which will give him the greatest crops, leaving the surplus acres to other uses. If a man, by good culture, can obtain from ten acres of land the same crop which it now takes from fifteen to twenty to give, then prepare the land so as to obtain the greater amount. That there are thousands of acres that now do not yield more than from 30 to 40 bushels to the acre, that would, with thorough culture, yield from 70 to 80, none acquainted with our agriculture can doubt. But we have heard it said, "If I employ all my labor and manure on ten acres, the remainder of my fields must suffer." The answer is easy: why cultivate 20, when you can get the same quantity from 10? and will rest from cropping be more injurious to the soil, than the exhausting process of cropping without manuring? Why spread the labor and the manure that applied to ten acres would give 800 bushels of corn, over thirty, and in the end receive but 600 bushels? Let it be remembered, too, that a piece of land, once thoroughly fitted and manured for corn, is fitted to produce a succession of good crops, which, in all probability, would more than repay, in their extra product, any extra expense incurred for the corn.

As the season for planting corn is approaching, we have collected from various sources, notices of some remarkable corn crops, mode of culture, &c. In the selection of examples, reference has been had more to the details of treatment, than to the amount of the crop, as it is of but little use for a farmer to publish to the world that he has grown an extraordinary crop, unless he also shows how he has done it. For this reason, we have omitted some of the heaviest crops of corn on record. And here we would remark, that in awarding the premiums for crops, our agricultural societies have not sufficiently insisted on full details of culture from the applicants. In consequence of this neglect of details, one great object of such associations has been defeated, and the good effected by them proportionably limited. This, every one must feel, who turns to the reports of the societies in the different States or counties, with the view of ascertaining the best method of culture in all its parts, of any given crop.

The first instance we shall select is from the report of a crop made by Mr. Stevens, of Hoboken. We do this because it is one of the earliest of our great corn crops, and shows the action of street sweepings or manure, very plainly:

"Mr. Stevens gave his ground three plowings before planting, and before the last plowing put on 700 cart loads of street manure. He then planted in double rows 5½ feet asunder, dibbling in each grain. To do this with expedition and accuracy, he bored two rows of holes in a piece of board about four feet long, so as to form equilateral triangles, the sides of which were seven inches, as thus:

* * * * * * * *
* * * * * * *

Into these holes he drove pegs 3½ inches long. As the corn was dropped into the holes so made, a man followed with a basket of rotten dung, with which he filled them up. During the season the corn was suckered three times. The intervals were repeatedly plowed, and the rows kept clean of weeds by hoeing and hand-weeding."

This corn was raised on a bet of 50 guineas between Mr. Stevens and a Mr. Ludlow. Mr. L. planted his rows four feet apart, and the corn 8 inches from stalk to stalk in the rows. His ground was manured with 200 loads of street dirt. His crop was 98 bushels and 14 quarts per acre; Mr. Steven's 118 bushels and 2 quarts per acre. Unless the great quantity of street manure used made it necessary, or the condition of the soil was bad, no good reason can be given for so many plowings for a corn crop.

In 1831, B. Butler, Esq., of Chenango county, in this State, raised 140 bushels of corn from one acre. The soil was a stiff loam, nearly covered with small stones, of which 50 loads to the acre were taken off before tillage. It was plowed but once, but this was done in the best manner. Mr B. adds:

"We then drew on 25 cart loads, (about 25 bushels to the load,) of sheep manure, and spread it evenly on the furrow—rolled and harrowed with the furrow, with a light double harrow, containing 40 teeth, until it was a complete garden mold, and the earth well incorporated with the manure. Again picked off the stones, and again rolled and planted on the 22d and 23d of May, on an even surface, with the early small white flint corn steeped in a solution of

copperas and saltpetre, and then tarred and rolled in plaster, and planted in double drills 3½ feet from center to center of the middle drill. The plants standing singly from 12 to 13 inches on the main drill. The corn was once plowed, and afterwards kept clean with the hoe, plastered well on the plant, topped at the usual time, was ripe on the 15th of September, and was harvested on the 14th and 15th of Oct.

In this case, the sheep manure sustained the high reputation it has acquired for the corn crop, both at home and abroad, and with the exception of that produced in the hog pen, our experience would lead us to prefer the manure from the sheep fold, to any other ordinary farm manures. One thorough plowing was here found sufficient, the rest being left to the harrow; and we are convinced that in most cases one plowing well done, will be found better than more. A fine mellow seed bed must in any event be had, and the soil must be moved with either plow or harrow until this is provided.

Another example of a good crop of corn, is that of Mr. Bugbee, of Palmer, Mass., who raised from five acres of land 540 bushels, or 108 bushels per acre. The following is the account given by Mr. B. of his mode of culture:

"Last spring, I plowed up a piece of green sward, measuring about five acres, and prepared it for corn as well as my means would permit. After plowing, 30 loads of manure to the acre, were spread over the ground, and thoroughly mixed with the earth by means of the harrow, without turning up or breaking the sod. The ground being now prepared, on the 30th of May I planted my corn. A small quantity of ashes, lime, and plaster of paris, mixed together and prepared for the purpose, was used at the time of planting, or put in each hill. Of this mixture, there were 2½ bushels of lime, 2½ bushels of plaster, and 25 bushels of ashes for the 5 acres. The corn was hoed but twice, a third hoeing being unnecessary."

This crop affords another of the many proofs already existing of the excellent effect of such a compost of lime, plaster and ashes, especially on inverted sward, as that prepared by Mr. B. Those farmers who sell off their ashes, and harvest corn crops of only 30 or 40 bushels per acre, would do well to imitate Mr. B. in the use made of his.

In 1823, Leonard Hill received the premium offered by the Plymouth (Mass.) Ag. Society, for the best crop of corn. We condense his statement of the culture, &c. The soil naturally was deep and rich. During the previous winter, while it was greensward, his cattle were foddered upon it. In May, it was plowed very deep into squares 2 feet 7 inches in width. It was then manured in the hole, 64 cart loads of barn manure being used. It was planted early with white and flesh colored corn, varieties having small cobs. The kernels were placed about four inches apart in the hills, not thrown together as usual. In the middle of July, the corn spindled, grew very thick, and so filling the spaces that the rows were scarcely discernible. It was hoed three times, and all the suckers early cleared from it. It was gathered on the first of October. The quantity of shelled corn, ascertained by disinterested men, was 139 bushels, 3 pecks.

This was a great crop, but the account is defective in not stating the number of stalks left in each hill. The varieties of corn must have been of the small kind, or such close planting would have prevented the formation of ears. The quantity of manure was enormous.

Some of the most extraordinary crops of corn ever grown in the United States, were those produced by the Messrs. Pratt of Eaton, Madison county. In 1822, they obtained from 3 acres, 517½ bushels, or 172 bushels per acre, and in 1823, from 4 acres, 680 bushels, or 170 bushels per acre. They prepared their land in the best manner, then with a shovel plow made a trench 20 inches wide, into which the manure is placed and covered. On these trenches, so covered, the seed corn was drilled in three rows, thus:

* * * * * *
* * * * * *
* * * * * *

Two feet nine inches distant, or 3 feet 9 inches from centre to centre of the rows. Another trench was made, filled, covered and drilled in a similar manner. Thus the corn stood in single stalks, 6 inches apart every way, and 2 feet 9 inches clear between the rows.

It is evident that, planted in this manner, more stalks would be placed on an acre than in almost any other way, but nothing short of the most heavy manuring would carry through such a crop. We have found, by experience, that in very dry summers, close planted corn suffers far the most, and if too near, is a total failure.—We once planted a piece 2½ feet by 18 inches in the rows, intending 3 stalks to the hill. The corn was manured in the hill. The growth was very rapid and promising, until the ears were about setting, when a drouth of some weeks occurred, and the result was not more than half a crop. The years in which Messrs. Pratts' crops were grown, were of the most favorable kind, and the crops, under their course of planting and culture, most astonishing.

In 1835, Mr. Brewster, of Oneida county, communicated to Judge Buel an account of a crop of corn and potatoes, raised by him in that year. He says:

"I had a ten acre lot of stiff strong sward, that had not been plowed for many years; this I intended chiefly for Indian corn. In one corner of this, I measured off one acre for corn, and by the side of it another acre for potatoes. I drew on about twenty loads of yard manure to the acre on each, turned it over, followed the plow with the roller, harrowed and furrowed three feet apart from north to south, and put down about the same quantity of manure that was turned under. Commenced planting the 20th of May; seed soaked, rolled in tar and water and plaster, put 4 grains in a hill, one foot apart.—The first day planted one-fourth of an acre, which came up well; the other, planted on the 22d and 23d, did not come up well, owing, as I thought, to the seed lying too long in the hot sun after being soaked, and we replanted it on the 2d and 3d of June."

From the ¼ acre first planted, Mr. B. had 26 bushels 8 qts., or 105 bushels to the acre; the other ¾ did not do so well, and he only got 94 bushels and 2 quarts of shelled corn from the acre. The potatoes were planted on the 1st and 2d of June, furrows three feet apart, and the seed all whole and large, dropped one foot apart in the rows. One good dressing was given them with the plow and hoe, which was all the attention they received. At gathering, by measure, he had 519⅓ bushels, by weight, 560.

Several years since that excellent farmer, Mr. Reybold, of Delaware, on a field of 22 acres, raised 2216 bushels of corn, or 100¾ bushels per acre. Seven years previous to the crop, he put on 60 bushels of lime per acre, and planted it to corn; in the following spring, he put it in oats; in the fall put on 40 loads of barn yard manure per acre, and sowed it to wheat and timothy seed, and the ensuing spring with clover. It remained in grass some five years, and received one top dressing of 40 loads per acre of manure. It was mowed four or five years, and gave from 2½ to 3 tons of hay per acre. In the spring of 1835, he gave it another dressing of 40 loads per acre of long manure, allowed the grass to start through it, and then, with a furrow ten inches deep, turned the whole under. The corn was planted in shallow furrows 3½ feet each way. The plow was never used in the field after planting, the cultivation being performed by the cultivator and hoe; and no hilling was allowed. Three good stalks were left on each hill; when the corn was glazed it was cut up, and put in shucks. On this statement, Judge Buel remarks:

"The management which led to this extraordinary product of corn, should be deeply impressed on the mind of every farmer.

1. The ground should be well dunged with long manure.

2. It was planted on a grass ley with one deep plowing.

3. It was well pulverized on the surface with the harrow.

4. The plow was not used in the after culture, nor the corn hilled.

5. The sod was not disturbed, nor the manure turned to the surface; and 6th, the corn was cut at the ground when it was fit to top."

We had marked several other crops as worthy of note, but have room for only the following, which we select as showing what crops of corn may be grown on the very northern verge of its culture, and what the treatment was that produced it.

The soil was gravelly, dry, had been cropped seven years in succession, and manured each year. In the spring of 1838, the hills of the previous year were split, a good dressing of manure put on and plowed in, harrowed, and with a light plow opened into drills 2½ feet apart. On the 19th of May, 1¾ bushels of seed corn was put in a tub, and hot water poured on it, till too hot to stir with the hand. It was steeped two hours, then dried by rolling in plaster, and planted the same day in hills 16 to 18 inches apart, and from 5 to 7 kernels in a hill. On the 5th of June, it had come up; on the 11th, a small plow was passed between the rows lightly, turning the little mold raised to the middle, and care being taken to stir the whole surface of the ground. It was harrowed and hoed the next week, and again the week after that, the owner believing that the maturity of corn may be hastened some two or three weeks by frequent hoeing, while the plants are young. In hoeing, the earth was left nearly flat. On the first of September, the corn was cut up, and husked out the last of the month. The crop, when shelled, fell a few pounds short of 150 bushels of corn per acre. It should be stated, that though plenty of seed was used, only three stalks were allowed to remain in a hill, the best being selected or this purpose.

From the history of corn crops here given, and the mode of culture adopted, we think farmers may derive some useful inferences. We have omitted the great crops of Kentucky, 190 and 196 bushels to the acre, the largest yet grown in any country, as the details of culture were not at hand; and the same may be said of some of the premium crops in this and other States. We state here a few of the most prominent results disclosed:

1. The soil intended for corn must be dry; all experience proves that moist soils are unfit for the culture of this grain.

2. It should be made rich, and deep. Corn will bear heavier manuring than any other cultivated plant, and the soil should be deep to permit the roots to descend beyond all danger of drouth.

3. Preparation of the seed is useful; but no seed over-soaked or swelled for planting or sowing, should be allowed to become dry, as that injures its vitality.

4. The use of top dressing, such as mixtures of ashes, lime, plaster, &c., is established beyond a doubt, Perhaps there are few ways in which labor is better expended, than in placing such composts about corn

5. The uselessness of hilling corn is demonstrated. Not a great crop of corn has been grown for years, in which this practice has been followed.

6. It is proved that corn too thick will not ear; but that in some seasons it will bear to be thicker than others. The failure stated by Mr. Betts, of Newburgh, in the February No. of the current volume of the Cultivator, may be traced to this cause.

7. The impolicy of throwing all the corn put in a hill, when planted, together, is forcibly shown by the success of planting in drills of a single kernel, as in the case of the Messrs. Stevens and Pratts. We frequently hear men

boasting how much they have planted in a day, when, by planting the grain together, they lose more than would pay for many day's work.

We do not expect that every man will raise a hundred and fifty bushels of corn to the acre, even should he use every reasonable effort.—There are too many concurring circumstances, all of a fortunate kind, required to make such crops common; but that any good soil, skilfully cultivated, may be made to give 70 or 80 as a medium crop, we fully believe. Fewer acres planted, and those better manured and tended, would, we are confident, much increase the corn crop of the country, as well as the profits of the farmer.

From the American Farmer.

LARGE CROPS OF CORN.

Corn planters, who are in the habit of growing from four to six barrels of corn to the acre, are very incredulous as to the possibility of raising a hundred bushels to the acre; and yet there are a thousand instances of the fact recorded from time to time in our journal. Could we spare the time and space, we could fill a dozen papers with such facts, well attested; but, as we have neither at our disposal, we shall content ourself for the present by copying the following article from the Albany Cultivator. Its re-publication should, and we trust will, excite a laudable spirit of rivalry, as what one man has done another may do:

The great crop of the United States, whether we look at quantity or value, is unquestionably our corn crop. Four hundred and fifty millions of bushels in 1840, and probably 500 millions in 1842, show the importance of this grain to us. And yet the quantity now grown is nothing, a mere drop in the bucket, compared with what we might do, should circumstances render it advisable to increase the production to an extent that might easily be reached on the present cultivated lands of the Union. In order to show at a glance what might be done, we have taken the pains to collect a few instances of good crops that have been grown among us, and would remark that on a very large portion of our soils, in favorable seasons, and with the cultivation corn should receive, crops like the ones named may as well be grown as inferior ones. It is true, we now and then meet with a farmer or writer who asserts that no man ever saw 75 bushels of corn grow on an acre, and that the farmer should be contented with 25; but the only emotions excited by such are contempt for the ignorant confidence shown, and pity that in this country men should be found so far behind the times.

The number of such crops, where the product exceeded 100 bushels per acre, might be extended to a great length from the list in our possession, but the above is sufficient.—Still we imagine some farmers will say, (some have said so,) that the man who puts manure and labor enough on an acre to get 100 bushels of corn, is a loser. We would ask how? A man may cultivate an acre of corn, and get 30 bushels an acre, and he will be a loser; but it is scarcely possible when the product is 100. In such a case, all over 30 bushels may be considered profit. In addition to this, his acre of land is placed in a condition to produce more good crops, and the additional amount of these is to be added to the list of profits. The man who has brought 30 acres of land to such a state that it will produce 100 bushels of corn per acre, is far better off than the one who has 100 acres, yielding only 25 bushels per acre; and of this fact we are happy to find many of our farmers are beginning to be well convinced. It is unnecessary to say the remarks we have made respecting corn, are equally applicable to any other grain or grass, and that the grand secret of success is to cultivate no more land than you can make rich.

From the American Agriculturist.

TOPPING COTTON.

The December No. of your ever-welcome paper came to hand this day, and among its useful articles, my attention is drawn to that from C. McD., of South Carolina. I must first thank him for the kind manner in which he has alluded to my articles on the culture of cotton, as published in your work, and acknowledge to all whom it may concern, that I do indeed feel happy in having done some good; of having somewhat returned benefits for the very many I have received from farmers and farming papers. The amount of knowledge I have gained by personal experience is too limited to benefit any one; I am therefore indebted to books, papers, and men, for all I am able to retail second hand. Mr. McD. refers to the topping of cotton, and says he does not recollect that I touched on the subject. I did not; not that I thought its advantage at all questionable, but partly oversight, and partly because it was so seldom resorted to, that I feared to be considered as recommending anything questionable, thereby injuring the utility I hoped to accomplish in the articles written for your paper.

In the summer of 1832, I think, Mr. John Thomas, of South Carolina, visited me, and among other practical lessons, he urged on me the utility of topping cotton—declaring that it would well repay for the time, whether it were cotton that would yield only 500 lbs. of seed cotton, or of that which yielded 2,000 lbs. To make his declaration as strong to others as to myself, I here state, that this gentleman at the date mentioned had some 200 hands, was a cotton-grower, and had cultivated it for some 20 to 30 years, on the rich lands of the Congaree, as well as higher up the country on Broad river; he was an intelligent man, and truly a warm-hearted southerner—he is now no more.

In consequence of his urging me to try it on a small scale, as this country was new to both of us, I did so, and have had cause to follow it up ever since—sometimes neglecting at the proper time, from pressing occupations, or the season. I kept no memorandum of the difference, though I commenced farming, by keeping notes; but I am confident if followed up, that it will be beneficial two out of three years; and on most lands, will not injure the third year. I give my reason why it may not benefit every year. If the season is wet after the time of topping, say from the 25th of July to the 5th or 10th of August, there will shoot up water sprouts, which will shade the under bolls so as to prevent them opening well; it will make a heavy top crop of bolls, which will cause the stalk to bend down, and if any wind comes with the rain, the stalk can not regain its upright position. If the season has been very dry, the cotton will pretty much cease growing by the time of topping, and will not then be advantageous, unless done earlier—which, if I ever have another chance, I will try.

Topping is advantageous for the following reasons: the forms or squares, and small bolls, will not be cast off so readily, the upper bolls will mature sooner, make less leaf to be falling on the cotton, and the top bolls, principally, will be larger than otherwise. Last year I topped cotton on the first day of August—this year I did not top at all, owing to the wet season. I would not top cotton during a wet year, till I had more knowledge on the subject, for fear of the water shoots, but would not hesitate if a dry one.

Benefit of Manure for Cotton.—I have not seen marl used, but I can satisfy any one who doubts the effect of manures for cotton, and of cotton-seed especially—that no man ought ever to think of leaving a level farm, the house and friends of his childhood to seek rich lands. This year has been more favorable for thin lands, than usual; but whether for stiff clays is rather doubtful; and whether any manured land did better on this account, I know not—but here is the result. My orchard lot contains 24 acres, in which are ½ an acre in grass, ¼ in a flower garden, and near ¾ in roads and gin-house; I therefore say there are 23 acres in cotton, 9 of which were manured with cotton-seed, and about one with barnyard manure. From the 23 acres I have gathered an average of 1,138 lbs. per acre. The poorest land on the place, and the poorest portion was manured; a part of the unmanured, say 4 or 5 acres, could not have averaged over 700 lbs. per acre. This field has been in continued cultivation since 1825; has on it some 270 peach-trees, 3 years old; 50 small pear, apple, and cherry, with some 30 large peach-trees; besides, two rows of morus multicaulus, forming an avenue to the house. If the trees were deducted, there would not be over 21 acres, which would give me 1,150 lbs. on an average; with enough more, if gathered, to make 1,300 lbs. Another field that is high and dry, gently undulating, cleared in 1833 or '34, and is much richer land, will not give me that average, and was at no period of its growth as good, as was the manured portion.

Pleasures and Advantages of Remaining at Home.—Let any man "cypher" up the cost of moving—the cost of land—the cost of building—the cost of clearing—to say nothing of the deprivations in a country where farms are to open—the loss of dear associates—our schoolmates—and the time required to prepare for making money, and I venture on it, no sane man will move. I want to see many from those old countries here: not that, Indian-like, I wish them to suffer because I have, but that I want a thicker-settled country, and more demand for land. Yet, with all this, I would recommend them to improve at home where they now are; husband their resources; study the economy of manures, improve agricultural implements, stock, seeds, and the best rotation and management of crops.

Would that man merit aught but opprobrium, who would urge his fellows to sever every tender tie that binds him to "Home, sweet home;" to even the "old oaken bucket;" to the soil; to his associates and relatives, for the purpose of getting richer land, which, when cleared and cultivated, as is now done, will cause the young flock to wander again—and, in reality, only serve to support one generation? I say nay, and therefore urge it on our brother farmer, C. McD., as on all others in that good old State, to make it a part of their regular business to save, gather, and make manure; they will find that three years of labor, with the cost and loss of moving, will give them such lands, that they will cling to the "old south state," even if they live in the "Peedee country—God bless you."

Leibie's Letters.—I have just finished reading Leibig's Familiar Letters, and a capital fine thing it is. I wish it had been published prior to his other works, as I think it would have been more generally beneficial; whereas, many who

purchased the first works of his, have not read them through, and will suppose this to be a similar work. But the form of letters makes it indeed "familiar," and it treats on "familiar" subjects. M. W. PHILIPS.

Log Hall, Miss., December 21st, 1843.

From the Albany Cultivator.

LETTER FROM THOMAS AFFLECK, ESQ.

We give below some extracts from a most interesting communication received from our friend, Mr. Affleck, of Ingleside, Miss. The extracts relate to topics of interest at the north as well as the south, and will aid in throwing light on the productions and modes of culture in that fertile section of the Union. The doubts which have existed as to the capability of the south to produce its necessary provisions, or to grow the principal varieties of northern fruits, doubts which had arisen more from the neglect of the planter than any other cause, will soon be dissipated by the example of a few such men as are now engaged in enlightening that section of the United States as to its capability and true policy.

Mr. Affleck has transmitted to us two specimens of cotton in the seed; one a specimen of good Mexican, and the other a specimen of that shown by Dr. Lovelace, at the Adams County Fair, Miss., and supposed to be a hybrid between the Mexican and some long stapled cotton. Dr. L. not having completed his experiments, did not disclose the manner of its production, but we can say that a more beautiful specimen of cotton than the improved, has never met our eye, and shows most conclusively, we think, what a field is open for the well-informed and scientific cultivator, in the improvement of this national staple.

The following request of our friend, we place here, that it may meet the eye of Dr. Cloud:—"Let me beg of you, as I do not know his address, to say to Dr. Cloud, that if he will forward me a bushel, or what he can spare, of his *improved cotton seed*, to the care of Ringgold, Ferridy & Co., New Orleans, he will confer on me a favor that I will gladly reciprocate." The extracts relating to sheep, pigs, and growing corn for fodder, will, we are sure, arrest the attention of the reader:

"There is but one difficulty as to pastures, and that is, that none are made. No one attempts to form pastures in any other way than by turning out fields after they will no longer produce cotton or corn, and being satisfied with the scanty crops of sedge and Natchez grass, and of briars which they may yet be able to support. Within the last year or two, however, better things are attempted. I have seen very promising woodland pastures of orchard grass; and winter pastures of Egyptian oats and rye are becoming common on well managed plantations. The cane swamps afford tolerable grazing; at all events, the swamp cattle manage to grow and even fatten on the abundant browsing they find there, and make pretty good beef and capital work oxen. These are the rams-horned, brick-colored cattle, known as Piney woods, swamp, Opelousas, or Attakapas cattle—descendants of the original Spanish stock, and yet found in those regions, uninjured and unimproved. During the winter, we have no lack of abundance of feed for all kinds of stock; and in summer we have only to have recourse to Bermuda grass, to keep every thing sealtat. This is the most nutritious grass I have ever seen; and where exposed, the most closely grazed. It resembles Nimblewill, (Triticum repens?) but is more delicate in its appearance, leaves much more numerous and narrower, stems small and solid, growth rapid; and when in meadow, it does not attain a height of over 12 or 14 inches. Yet I have seen this delicate looking grass afford, at a second cutting, between 5 and 6 tons to the acre of dried hay. The first and third cuttings not so good. It stands so thick on the ground, and its numerous lateral leaves so closely interlocked, that a good hand cannot cut over more than half an acre per day, and has to cast aside the swarth with his foot, at every second or third cut; the scythe blade passing under and cutting the grass, without laying it over. It is a troublesome grass in the cotton field, but can be got under by a crop of corn and pumpkins, or oats followed by peas; it can bear little or no shade. It is invaluable for coating embankments, and is of incalculable benefit on the levees of the Mississippi. It is stated upon good authority, to be 'the Doul grass of the middle provinces of Hindostan.' Whoever brought it to this country, is as deserving of a monument to his memory, here in the South, as is Parmentier in France.

"Within some three or four years, another creeping grass has made its appearance here, said to be a native of and abundant in Cuba, and is rapidly spreading; that suits their upland, and thrives better there than Bermuda, and is green and grows all winter, whilst the other is cut down by the first frost. I am now using it in my garden and grounds for edgings, grass plats, &c., and think it will answer well, as being easily kept within bounds, of a dwarfish growth, forming a close sod, and remaining green summer and winter. From the reports of Dr. Phillips and others, it would appear that in the Musketo, a Texian grass, we have another valuable resource, particularly for winter pasture. Dr. P. presented me with a small quantity of seed, which is in the ground.

"You see how I ramble along! I will now return to my forgotten text, Sheep in the South! You are right,—'the old notion of the impossibility of growing good wool at the South, is giving way to the evidence of facts.' The doctrine that all wool-bearing animals except the negro, have their wool, in a very short time, turned into hair in the South, is also exploded. True, the common sheep of the country, bred in and in for generations, and ranging now in miserable burnt up pastures, and again in the cotton fields, where they become excessively fat on the tender winter grass; the one season shorn, and the next allowed to surrender their coats to the briars—such sheep have thin, scanty, hairy fleeces. But they form no criterion. Are there no such animals elsewhere, 'bred by, and the property of nobody in particular, the United States over?' Why is the coat of the black-faced sheep of the mountains of Scotland, so coarse and hairy, whilst that of the Merino of Spain and of New South Wales, where they scarcely ever see frost, so fine in its staple? I feel satisfied of one thing, that the finer and more spiral the staple, and the closer and heavier the coat of wool, and the greater the abundance of yolk, the better will the wool on the sheep's back resist the injurious effects of the sun. Sheep are kept by the planter, in almost every instance, for the mutton alone; some few manufacture the scanty crop of wool. The mutton is very fine, almost equal to that of the mountain heather-fed sheep of my native country—and that, you know, is a great deal for a Scotchman to say! The native sheep of which I speak, are remarkably full and broad in the loin, and the saddle is of course proportionably good. Sheep seem to me always to be in good health here—one never hears of the halt of a large flock dying off within a few days, as is by no means unusual in colder countries, where numbers have to be penned together for a considerable length of time.

"We have thus, you perceive, no scarcity of beef and mutton. Many planters in Mississippi are now making their own pork, or are exerting themselves to do so. In the neighboring County of Jefferson, this is more particularly the case. I know of several there, who last season killed and cured from 100 to 200 head; one who killed 350, and another over 700 head, all for their own home consumption. The gentleman last alluded to, assured me that all of his hogs were fattened entirely on peas, which were planted between the corn rows at the last tending, and the hogs turned in on them after the corn is gathered; finer bacon I have never eaten. This gentleman has killed his own pork ever since the second year of his farming, some thirty years; tans his own leather, makes his own shoes, harness, &c., wagons and farming utensils; manufactures much of his winter clothing, and this without allowing himself to be influenced by the high or low prices of cotton; though, of course, when cotton brought from 15 to 25 cents, he was, to all appearances, sinking money in employing his hands anywhere else but in the cotton field. However, the best proof that his system was the true one, is that he is one of the wealthiest men in the country, living in the greatest comfort, his family settled round him, and his negroes comfortable and happy.

"A word more on hogs. I find that the pigs brought here from the North, grow none after warm weather sets in; and grown animals suffer much during the first summer; whilst their produce, bred here, grow and thrive well. I have imported Newberry here, and a fine lot of thorough-bred sows, from which I am raising my plantation stock—will they do?

"You speak of being 'anxious that some of your southern friends would try the experiment of sowing corn broadcast, as an article of food for animals, to be used for soiling during the summer, and cured and fed, after being cut, to them in the winter; and ascertain what the practicability and expense of keeping animals in this way would be.' Corn leaves, you are aware, are now used extensively; but would not the stalk, cured and cut into chaff, add much to the ability of the planter to feed stock, without materially adding to his expense? It would, and in my own case, does do so. At 'Ingleside,' I feed nothing else. My farm here only consists of 40 acres of an old field, which the small force I keep here enables me to improve very slowly; the more, as to it is added five acres of garden, &c., requiring much manure. As I keep five head of horses, two mules, two yoke of cattle, from two to six cows and their calves, and some twenty to thirty head of hogs, I was forced to try some such means of making fodder, or have blades to haul from one of the plantations. In 1842, I sowed some corn broadcast, but the dryness of the season and the poverty of the land, prevented it doing much. I did not cut it; but the stock, when turned into the field, grazed on that patch of corn as long as there was a stump of it left. That winter I fed principally on crab grass hay, and corn cut and shucked Kentucky fashion—which does not do well. This last season I drilled several different patches of corn at different times during the spring and summer; drills from 2½ to 3 feet apart, and the stalks almost touching in the drill. It all did well; so well that though I had not more than an acre and a half in all, I fed my stock on it during the whole summer, passing the green corn through the cutting-box, with a proportion of about one-third or one-fourth of dry fodder; cutting down and curing what was left of each patch, when the next sown became ripe enough to feed out. I have thus sufficient fodder to do me, I think, or nearly so, until oats are ripe, and my drilled corn comes in again. It must be in tassel, or tasseling, before horses and cattle at all relish it; and hogs, though they eat it greedily, fall off on it; for the reason, I think, that they reject all but the juice, and hang round the fence all day, waiting for more. I have tried Egyptian millet and Guinea corn, but prefer the maize.

"Pulling corn blades to make fodder, I consider the most unhealthy and unprofitable work done on the plantation."

CURRYING COWS.—Cows should be curried as often as horses, particularly when they are shedding their hairs. Independent of other consequences, it tends to prevent them from licking themselves, by which they often swallow the hair and receive injury.

TO PREVENT THE BLEEDING OF VINES.—If a piece of moistened bladder be folded over the end of the vine which is cut, and then bound tightly around with wrapping thread, it will effectually prevent bleeding.

WEDNESDAY, MARCH 20, 1844.

THE BACK VOLUME.

All new subscribers who may desire it, can obtain the first volume, neatly bound in boards, at one dollar the volume.

☞We must throw ourselves upon the indulgence of our readers, for the delay in the appearance of this number. So many of our compositors have been confined, during the last ten days, with the Measles, that it was impossible, as we could not supply their places, to make a more rapid progress. The same cause may delay, for a few days, the issue of the next number—after which, we hope to appear with our accustomed regularity.

AGRICULTURAL PAPERS FOR DISTRIBUTION.

The following paragraph, which we find in the "American Agriculturist," we commend to the attention of Southern Planters, as well for the excellence of the example as for the evidence it bears of the zeal of our Northern brethren in the cause. On reading it, we were forcibly struck with the contrast which it presents between Northern and Southern Agriculturists. It is by no means flattering to our Southern brethren; and, as those are said to be our best friends, who tell us plainly our faults, we will sketch the outlines of the pictures as they were presented to our mind, and invite you to look first upon one picture and then upon the other.

Throughout the Middle, Northern and Eastern States, Agriculturists have attained a higher degree of proficiency in their vocation than any other portion of the Union. There, almost the whole face of nature, the very fields, are in as high state of cultivation as the great mass of the gardens at the South. Every thing bears upon its face the impress of enterprise, zeal and progressive improvement. The farmer clears his lands and cultivates them, not to exhaust them by a system of cropping, which annually diminishes their production, but his constant effort is to enrich them and increase his crops.—Now, to arrive at the proper manner of doing this most successfully, he is content to be taught by those who, combining a higher degree of scientific attainment, have tested their discoveries by experiments. Hence, he supports and reads Agricultural papers; and when he has seen and felt the good effects thereof, upon his constantly improving soils and his well-filled granaries and store-houses, his zeal in this great and most philanthropic cause is aroused, and he is not content that he alone shall reap the benefits of Agricultural journals, but he becomes desirous that their influence should be extended to every class of society—and therefore resolves upon gratuitous distribution. This is true patriotism—it is the very essence of philanthropy; and yet, this is done by a people who are not unfrequently sneered at by our Southern brethren for a want of liberality—and sometimes charged with a "littleness" in money matters amounting to meanness.

That is one side of the picture. Now, let us present the other: but, before doing so, we beg leave to remark, that we are wholly and entirely identified with the South, by birth, education, feeling and interest; and we therefore claim the right, and assume the privilege and responsibility, of talking to you plainly. If our frankness offend any, we shall regret it—nevertheless, it is a duty we owe to ourself, as well as the great cause which we are zealously endeavoring to support and sustain, that we deal candidly.

What, then, we ask, is the state of Agriculture and Agricultural improvement at the South? We ask every man, who reads this article, to stop here and look around him, to see and contemplate the vast amount of land which has been exhausted by a system of culture, the very reverse of that practiced by our eastern brethren, and is now turned out to waste. Enquire, if you please, who, among all those who are thus annually destroying the productive properties of the soil, reads an Agricultural work. Go among those destructives of the soil, and seek to enlighten them upon that subject, which most pertains to their interest and happiness, the improvement of their lands, and learn how often you meet the response—"No man can tell me anything about farming." Ask them to subscribe for, and read an Agricultural paper, from which they cannot fail to derive much valuable and interesting information, and ascertain how often you are tendered as an excuse, "I have not time to read," and "I cannot afford to pay the subscription."

What a melancholy picture does such a state of things present to the eye of the philanthropist! Here are a people, strictly an Agricultural people, devoted to it from interest, habits and tastes, manifesting no interest or zeal for the improvement of that science, by which they derive their daily subsistence—pursuing, from day to day, and from year to year, a policy which impoverishes their lands, materially effects the happiness of the domestic circle, and cripples the commercial relations of the country; and yet, when you urge upon them the adoption of measures which are calculated to correct these increasing evils, you are told, with the coolest indifference, "we want none of these things." Yet, such is Southern Agriculture generally, and such are Southern Agriculturists, with some few honorable exceptions. There is, in truth, none of that zeal diffused among the great mass of the Southern people, which is such a distinguished characteristic of the Northern and Eastern Agriculturists. There is not to be found that spirit of liberality, (although we boast often that we are the very essence of liberality itself,) which prompts a planter, or even an Agricultural Society, to subscribe and pay for a paper for gratuitous distribution. On the contrary, in this money-loving age in which we live, the great mass seem to live for themselves alone—they have few cares for society, fewer for those who are to come after them; and, notwithstanding their great object seems generally to be the accumulation of more money, they neglect the most important means to be employed for the accomplishment of their purposes.

But we must desist—and, in doing so, beg leave again to call the reader's attention to the following paragraph:

THE AMERICAN AGRICULTURIST FOR GRATUITOUS DISTRIBUTION.—The Hampshire, Hampden and Franklin Agricultural Society of Massachusetts, has ordered 25 copies of our paper for gratuitous distribution among its members, with a view of giving a stimulus to an improved system of agriculture. We have also 75 copies ordered among the different societies of this State for premiums. We hope that this will be an incentive for others to go and do likewise. In all such cases we shall put our paper at the lowest possible rates at which it can be afforded.

VALUABLE SEEDS.—In our last, we inadvertently omitted to make our acknowledgements to the Hon. H. L. ELSWORTH, of the Patent Office, for a fine collection of valuable seeds, comprising several varieties of corn, wheat, garden seeds, &c. &c.

TEXAS COTTON SEED.—Our friend, JOHN W. GRAVES, of Newton county, has sent us about half a bushel of Cotton Seed, for distribution among our friends, which he describes as being very prolific, and producing a very superior article of Cotton. The concurrent testimony of his neighbors and overseers, to the same facts, are very conclusive and satisfactory—which we regret our limits will not permit us to insert today. We shall be pleased to distribute the few seed we have among our friends who will call at the office.

PEARIDGE, HARRIS CO., GA., March 8th, 1844.

MR. EDITOR—I noticed in one of the February Nos. of your valuable paper, a letter from W. W. Bates, of Eufaula, Barber county, Ala., in which he states that many hogs and cattle have been lost in his neighborhood, during last fall and winter, by turning them into pea-fields, and asks a remedy through the columns of the Cultivator.

I have been engaged in the pleasant business of farming for the last four or five years, during which time I have raised four crops of peas, which I consider a very important article of food for hogs. My practice is to feed my stock bountifully for three or four days previous to turning them upon peas, with a heavy feed just as they are turned in the field, where they remain until the peas are destroyed, having a free access to water and a plenty of salt and ashes during their stay. I am happy to say, I have yet to loose my first hog or horse from eating peas. I have never suffered my cattle to be turned upon fresh pea fields.

I am, sir, yours, &c.,

THOMAS H. BENTON.

☞The most valuable part of every man's education is that which he receives from himself, especially when the active energy of his character makes ample amends for the want of a more finished course of study.

From the American Agriculturist.

SUBSOIL PLOWING.

We are highly gratified to observe an increased attention to subsoil plowing, for we consider if it could be generally introduced among us, it would be found one of the greatest agricultural improvements of the age. In vol. I, page 199, we gave full details of the successful operation of the subsoil plow in England, where it was shown, that by its use, crops may be doubled without adding a particle of fertilizing materials to the land. Two years subsequent experience by the farmers of that country, corroborate the benefits to be derived by the free use of the subsoil plow, for grain as well as root crops. Mr. Tilley recently asserted before the Cornwall Agricultural Association, that he had the past year raised hundreds of roots of mangel-wurzel, weighing 25 lbs. each; that the crop of these per acre, as well as carrots and turneps, was at least doubled by subsoil plowing.

Five years ago we had a piece of land containing 2¼ acres of a hard clay soil, which, with the best management we could bestow upon it, yielded less than 150 bushels of potatoes to the acre, and 400 of sugar-beet—while parsneps, carrots, or any long roots, it would scarcely grow. We had just heard of Mr. Smith's subsoil plow in Scotland, and determined upon an experiment. We had no plow of this description, nor could we then obtain one; we accordingly took the mould-board off from a large, strong road plow, and used the point of the share alone for subsoiling. We plowed the land in the fall of the year, by taking a common plow and one yoke of cattle, and turning over a surface furrow six inches deep. We then followed directly after this in the same furrow, with three yoke of cattle attached to the road plow, stirring the soil eight inches deeper, making fourteen in all. This we then bountifully limed, and the next spring as bountifully manured and planted it with roots, and the following autumn obtained over 1,100 bushels of sugar-beet to the acre from it, and other crops in proportion.

Subsoil plows may now be had in this city, of excellent pattern and strongly constructed, from $10 to $15 each, which will stir the earth from 12 to 18 inches deep, requiring from two or five yoke of cattle to move them, according to the nature of the soil, and the depth required to plow.

From the American Agriculturist.

CULTURE OF ASPARAGUS.

Since the Spanish method of cultivating asparagus by the seashore has become known in England, a complete change has taken place in the manner of growing it there, salt being added now in moderate quantities to the manure used to enrich the beds; it is also spread broadcast upon them, at the rate of 1 to 3 lbs. per square yard, after forking them over in the spring. This makes it much more palatable and tender. The month of April in this climate, as soon after the frost is well out of the ground, is the best time to apply the salt dressing to the beds. A compost of horse manure, mixed with leaves and vegetable mould from the woods, together with a little charcoal, is one of the best manures we ever made use of for enriching the asparagus bed.

Visiting Dr. King's fine farm at Perth Amboy, last summer, we were walking with him one morning along its boundaries on the bay, when within a few yards of the water on a slight ridge of sand, which was subject to be wet by the salt spray, and inundated by a high tide, Dr. King pointed out to us a natural asparagus bed; and although it was late in the season for this vegetable, and most of this before us too much grown for good cuttings, upon our mentioning to him the Spanish method of cultivating it, he directed some of this to be cut and cooked for dinner. To our surprise, notwithstanding it was so old, it proved very delicate and palatable, and completely satisfied us that its superior taste was owing to the salt dressing it received from the sea-water. Gardeners, in the interior of the country, will do well to try the experiment here recommended with salt; it will cost but a trifle, and do no harm if it produces no good. We scarcely recollect eating delicate asparagus in the valley of the Ohio; it was generally of large growth, tough, and bitter, and none that we ever tasted at the west, did we find to possess the peculiar flavor of that growing naturally at Dr. King's.

To Select a Good Wife.—Choose a woman who has been inured to industry, and is not ashamed of it. Be sure she has a good constitution, good temper, and has not been accustomed to "*dashing*" without knowing the value of the means, is not fond of novels, and has no giddy and fashionable relations, and you need inquire no further—*she is a fortune.*

Illustration of Early Rising.—The difference between rising at five and at seven, in the course of forty years, amounts to 58,400 hours, or ten years, allowing eight hours in twenty-four for sleep. Thus, the man who saves these hours, saves in forty years ten.—These hours, spent in useful reading, having the balance of the day, if a laboring man, for meditation, would be equal to twenty years continual study.

LINNÆAN BOTANIC GARDEN
AND NURSERY—LATE PRINCE'S,
Flushing, L. I., near New York.

THE new DESCRIPTIVE CATALOGUE, not only of FRUIT, but also of ORNAMENTAL TREES, SHRUBS, and PLANTS, cultivated and for sale at this ancient and celebrated Nursery, (*known as* Prince's, *and by the above title for nearly fifty years,*)

WITH DIRECTIONS FOR THEIR CULTURE, may be had *gratis* on application to the New Proprietors, by mail, *post-paid.*

The collection at this establishment is unrivalled, and prices generally *very much reduced;* and the proprietors flatter themselves that the Catalogue will be found to surpass in extent of information and usefulness, any thing of the kind ever before presented to the public; and to be worthy of a permanent place in the library of the Horticulturist. ORDERS will be promptly executed. WINTER & CO.,
Flushing, February 17, 1844. Proprietors.

GARDEN AND FIELD SEED.

A GENERAL assortment of fresh and genuine GARDEN and FIELD SEED, among which are the following:

Red and White Clover,
Blue and Green Grass,
Rye and Orchard do.,
Timothy and Herds do.,
Millet and Lucerne do.,
Seed Corn of every valuable variety,
Seed Wheat,
Buckwheat and Potato Oats,

Kept constantly on hand by the subscriber, all of which are offered for sale at very moderate prices. All orders, by mail or otherwise, executed with neatness and despatch.

SOUTHERN CULTIVATOR.

VOL. II. AUGUSTA, GA., APRIL 3, 1844. No. 7.

COMMUNICATIONS.

For the Southern Cultivator.

☞ MR. EDITOR—Enclosed I send you one dollar, which I see, from your Prospectus, is the price of a year's subscription to the Southern Cultivator. This is what I should have done long before this, but for the belief, which I entertained from the first, that your truly valuable paper would not live out one year's subscription—that is, was destined, like many other works of a similar character, which have been gotten up at the South, to come still-born from the press, and perish for the want of patronage to sustain it. In this, I have been agreeably disappointed; for it seems I had greatly underrated the spirit and good sense of my brethren of the plow; and, by way of making both you and them some amends for past neglect and injustice, I now send that which alone, in my humble opinion, can render an agricultural paper profitable to the publisher, and useful to its patrons, viz: an addition to your subscription list, and to your list of contributors.

I have been a regular and attentive reader of the Farmer's Register and Albany Cultivator, from the period of their commencement up to the time when the Farmer's Register, (to the everlasting shame and disgrace of Southern planters, be it said,) was permitted to languish and die for the want of patronage--and of the Cultivator to the present; and, as a farmer and a man, I can say, truly, I have been signally benefitted by them. I shall always entertain the highest gratitude and respect for the memory of the distinguished founders of those two works. I have, however, long since seen and felt that the Albany Cultivator, ably conducted, and eminently practical and useful, as it is, is not every way suited to the circumstances and condition of Southern Agriculturists: for, although the Albany Cultivator is all that the great mass of its readers could desire it, yet it must, and does, necessarily contain a great deal of matter which is altogether inapplicable to our husbandry, and consequently of no practical utility to us. It is, therefore, with great pleasure, that I welcome the permanent establishment of an agricultural paper in Georgia; and I shall hail it as the harbinger of a higher and brighter improvement in the agricultural prosperity of our State. Different latitudes give rise to different climates, soils and productions, and consequently to different systems of husbandry. Hence, a system of agriculture which, in all its details, would be perfectly applicable to New York and the Eastern States, would not be at all suited to Georgia and other Southern States. There are, to be sure, certain great and leading principles, (which it is needless now to enumerate,) that are applicable to the well regulated agriculture of every country; yet, it is perfectly manifest to every intelligent farmer, that the carrying out of those principles in detail must be regulated by, and depend jointly upon, soil, climate, and the kind of produce most in demand, and which is rendered most profitable. It is precisely for this reason that it strikes me, every State should have an organ of its own agricultural interest, and that the farmers of Georgia should use all the means in their power to foster and sustain a work which is calculated to exert such a salutary influence in the agricultural reformation of our State.

The fact is, Mr. Editor, there is a large portion of Middle Georgia—and, indeed, I may say, of all the old counties in the State—that is completely worn out. The lands have been, by a succession of hard cropping, shallow up-hill and down-hill plowing, and other imprudences, denuded of a large portion of the richest soil, of which any country of similar extent could boast; and we are now reduced to one of three alternatives, either to be content with scant crops, poor returns for our labor and capital; and, in the end, with poverty; abandon our homes, and emigrate to the *far, far* West; or, to commence, in right good earnest, the work of improving our lands. I think a few facts will serve to show which of these three alternatives it is obviously the interest of every planter of Middle Georgia to adopt. Taking it for granted, that no sensible and industrious planter will be content with the first, I shall endeavor to point out, in this article, some of the objections and difficulties which lie in the way of choosing the second. In the first place, there are now no wild lands to go to. The Indian title to all the land, lying within the limits of the cotton growing States, has been extinguished. It has been the policy of the General Government, ever since it went into operation, to extinguish the Indian title to the land occupied by them, within the different States, as speedily as possible—and the consequence was, there has never been a time, within my remembrance, when there were not almost yearly acquisitions of Indian territory, in some one or another of the Southern and Western States. Good land was consequently very abundant and very cheap; and the effect of this abundance and cheapness of land, was to beget a careless, slovenly, *skinning* habit of farming. Indeed, the system of husbandry, which the first settlers of our country adopted, has often reminded me of the practice of hunting wild cattle, on those extensive Pampas in South America, by the Spaniards—where they slaughter, annually, hundreds and thousands of the finest, fattest cattle in the world, purely for the sake of the hide alone. And, as the skill and dexterity of these Spanish huntsmen is estimated by the number of cattle which they slaughter, and the quantity of hides which they take; so it would seem that the skill and abilities of a Georgia planter of the *old school*, was measured by the quantity of land which he wore out: for he who wore out the most land, was the hardest worker, and consequently the greatest *skinner*. The efforts of both are directed, with especial reference, to the *skin*, without any regard to the *carcass*. This *skinning* business, combined with the extended cultivation of cotton, the most exhausting and destructive to land, (when not skilfully managed,) of all other crops, has resulted most disastrously to the lands in the old settled parts of Georgia; and I heartily rejoice that the time has come, when these Georgia *land-flayers* will be necessarily compelled to desist from their *skinning* operations, and employ a portion of their skill and their efforts in curing and healing the wounds which they have so industriously inflicted. And I would here take occasion to recommend to the favorable notice of all whom it may concern, a certain *patent salve*, invented and prepared by Dr. Bommer, which is very highly spoken of by those who have tested its virtues, and is said to have a charming effect on all *ulcerated* land. If this should fail, it would be well to try a poultice of *muck*, which is highly recommended by Dr. Dana. One impediment in the way of agricultural improvement is now happily removed, for we have not now the comfortable assurance that a few more years will bring about another *Land Lottery*; and when our land is worn out, that just over the Oconee, the Oakmulgee, the Flint, or Chattahoochee Rivers, there is still a fresh country in reserve, waiting to be distributed by that most unjust, unequal and immoral, of all the modes of portioning out the public domain—a Georgia Land Lottery. The time is past, when land can be had without money and without price; and he who now comes into the possession of a landed estate, must expect either to inherit it, or to pay for it. If, then, we make up our minds to emigrate, the question forces itself upon us immediately, Where shall we go? Shall we go to Southwestern Georgia, New Alabama, Mississippi, Texas or to Oregon? Now, before we decide to take so important a step as that of breaking up and abandoning our homes, the country of our nativity, and of severing those ties which bind men together in a state of society, we should weigh well the inducements, we should count up all the cost, we should enumerate all the sacrifices, and be very certain that the balance is largely in favor of removal. If our inclinations lead us to Western or Southwestern Georgia, we will find that the land in those sections has long since passed from the red man into the possession and occupancy of the white man—that pretty much all of the good land and choice situations are already occupied, and those good lands and choice situations can now be had only by paying the highest sort of prices for them—prices ranging from twenty to thirty per cent. higher than lands in the old settled parts of Georgia. We shall be driven to the necessity, then, of paying higher prices for land, than land of similar quality can be bought for in our own immediate neighborhood—or, we must content ourselves with settling the poor land, which has been refused and rejected by all who have preceded us. Now, these difficulties will apply with equal force to every other cotton growing State, Florida and Arkansas excepted. As for Texas, I leave that out of the question; for I presume no prudent planter would risk the safety of his family and his property in a country so liable to revolution as Texas, unless it should be annexed to the United States.

To pay the prices for which good land has been selling in those sections, at the present prices of produce, would be ruinous. To break up, and encounter the expense of moving, the hardships and inconveniences, incidental to all new countries, to cultivate poor land, when we can get thousands of acres of poor land around our own doors for less money, would be foolish. The obvious conclusion, then, to which we must come, seems to me to be this: If we are compelled to have land, and prefer to pay a high price for good land, it is better to purchase it here; for, even in these old counties, there are still to be found extensive tracts of good land; or, if we choose to take the cheaper and poorer land, it is *better* to have it *here*—here, in this delightful region, where we can breathe a wholesome atmosphere, drink pure water, enjoy as good health as the people who live in the mountains; where we have good society, good

schools, good markets, a good currency, and *no repudiation*—than to plunge ourselves and families into those sickly countries, to breathe the poisonous vapors with which the atmosphere is loaded, to drag out a miserable and wretched existence, exposed continually to disease, pain and death. I do not here give assertion for facts. Unfortunately, the truth of this is attested by too many melancholy proofs. And here, by way of illustrating the truth of what I assert, I will give a few statements which will serve to show the fatal effects of the climate of those countries upon the inhabitants.

Between the years 1800 and 1825, there moved from this county, some twenty or twenty-five hardy, industrious, enterprising planters, who settled upon the rich river bottoms and table lands of Montgomery and Autauga counties, Alabama. Most of them were in their freshest prime—robust, hearty, hale men—choice specimens of the race of Georgia planters of the *old school*. Out of all this number, I know of but one who now remains. All, save one, are gone—gone to swell the list of that mortality which annually sweeps off hundreds and thousands into untimely graves; whilst many of their neighbors, who remained behind in this county, and who occupy the very plantations which they left, are still living.

Within the last eight years, between forty and fifty farmers have moved from this county, and settled in Southwestern Georgia, and New Alabama. More than half of these have died. None, it is believed, have greatly improved their estates. Indeed, most of them that have died, either left their estates insolvent, or greatly impaired.

Now, the fate of these men—sad and melancholy, as it is—has had, and will have, a good effect upon the planters of Middle Georgia. Their example will serve to teach us to appreciate, as we should, the blessings of health—to render us better content with our situation, and to cure us of that restless desire for change and pernicious novelties, which is so common to our race.

These are some of the reasons which have influenced me, (and I doubt not hundreds of others,) to come to the decision to spend the remnant of my days in this old worn out county; and to direct all my energies and efforts, as a farmer, to the preservation and improvement of my land. Having made up my mind to do this, and being a planter from choice, as well as from necessity, I am desirous of availing myself of all the helps within my reach.

A MIDDLE GEORGIAN.

Sparta, Ga.

From the Dollar Farmer.

VALUABLE IMPROVEMENT IN AGRICULTURAL MACHINERY.

Dean Swift once said, that "the man who makes two blades of grass grow where but one grew before is a distinguished public benefactor," and we think the commendation is equally applicable to the man who makes one ear of corn as beneficial as two were formerly. After all the great improvements of the last few years in breeding animals of the stock kind, there is one improvement worth them all—we allude to the great improvement lately made in feeding stock. Many valuable methods have been placed before the public for fattening stock in an economical manner, and the investigations on this subject have led to fruitful and valuable discoveries. We have no intention to review these things at present; our object now is to call attention to a branch of this department of agriculture about the value of which there is no contrariety of opinion—*the crushing of stock food*, by which provender undergoes the material process of mastication before it reaches the animal, the labor of digestion being thus lightened.

In a report, made by Mr. Coleman, to the Massachusetts Legislature, after a labored investigation of the subject, we find a decided preference for Indian corn, as the basis of the food of stock, and the author of the report thinks, that where seventy bushels of corn are the product of an acre of land, this is the cheapest food for animals. In order to make this valuable article still more important and useful, many machines have been invented, for crushing the corn and cobs, and the most of them are but sorry contrivances.

Of the value of corn thus prepared, no one can doubt, who has a proper knowledge of the subject. The intelligent and observing farmer, who should try the experiment of feeding a number of healthy animals on ears of corn, and the same number on the same quantity of corn crushed, would not be long without a machine for crushing it. An extensive feeder, for the Philadelphia market, says, "that a bushel of meal made of corn and cobs is fully equal to a bushel of meal made of corn and oats, and that animals never cloy on the first named meal." A member of the City Council of New-York, in speaking of the public yard, says, that "by cutting the hay, and grinding the oats, eight bushels of oats, and fifteen cwt. of hay fed the same number of horses, doing the same work, the same length of time, and kept them in as good condition, as twenty-four bushels of oats and thirty-five cwt. of hay did when fed whole."

In corroboration of these statements we have the following from the second volume of the Cultivator:

"The cobs of corn undoubtedly contain much nutriment. P. Minor, of Virginia, [see American Farmer, v. 1, p. 324,] has given us the results of a nicely conducted experiment to ascertain the amount of this nutriment. He took ten bushels of corn and cob, weighing three hundred and sixty-seven pounds, and ten bushels of shelled corn, and subjected them to the process of distillation. The product of the corn and cob was thirteen gallons of spirits, and of the pure corn eighteen gallons. Estimating that the ten bushels of corn and cob would have given five bushels of shelled corn, which is the general proportion, there will be left, as the product of the five bushels of cobs, four gallons of spirits, or nearly half as much as was afforded by five bushels of corn. Mr. Minor remarks that the cob affords other nutritive matter than the saccharine, which is converted into alcohol, as mucilage and oils. We have besides abundant testimony, in the practice of eminent farmers, of the utility of feeding cob meal to animals, always mixed, we believe, with meal of the corn or oats. Cob and corn meal is improved by scalding, still more, for hogs, by boiling, with potatoes, apples and pumpkins, and yet more by partial fermentation. All these preparations facilitate digestion. An animal high fed with raw grain, whether horse, hog or ox, voids much of its food in an undigested state, which is, of course, lost for all beneficial purposes. Grinding grain for animal food, therefore, is universally admitted to be economical, and cooking and partially fermenting it, it is no less true, further enhances its value for swine. Even the water in which it is cooked augments its nutritious properties, in consequence, probably, of some chemical change effected by the boiling operation. Fish subsist in pure water, as is strikingly illustrated in the management of the gold fish. The experiments of the Rev. H. Coleman, in fattening swine, further warrant this operation. 'At first,' says this nice observer, 'we employed half a bushel of Indian meal to make a kettle full of hasty-pudding; but we soon found that a peck of meal, by taking up all the water it could be made to absorb, in a thorough boiling, would make the same kettle full (holding five pails) of sufficient consistency.' In giving cob meal to horses and neat cattle, that are fed with cut hay or straw, there is a double advantage, at least so it is stated by those who are well experienced in feeding the grain and hay together. The grain, especially corn, is sometimes too heating to horses, and this tendency is counteracted by the stimulus of distensions, afforded by the hay and straw. Mixed feed of this sort may be fed thrice in twenty-four hours. It is eaten in so short a time as to afford much beneficial rest to the animal."

The observation, in this series of useful knowledge, on the rest given to the animal's digestive labors, by this mode of feeding, is of much importance. Cuthbert W. Johnson, one of the highest authorities in all agricultural subjects, says: 'Food should be so prepared, that its nutritive properties may be all made available to the use of the animal; and, not only so, but appropriated with the least possible expenditure of muscular energy. * * * All food should be given in such a state to fattening animals, that as little time as possible, on the part of the animal, shall be required in eating,' and he should have added, and in digesting.

The facts above cited show conclusively the great value of crushed food for stock. We know farmers in Jefferson county, who are so well satisfied of the value of ground food for cows, that they send twenty and sometimes forty miles to get corn ground into meal for them, and, although they lose the value of the cob, they think themselves remunerated for their labor and loss of time.

Among the various machines brought before the agricultural public for the purposes we have named, we have seen but one of remarkable utility. It is a crushing mill invented by Jas. Rowe, of Tenn., and there is one now in operation on the farm of Jas. W. Graham, of Jefferson county. For simplicity, durability and genera' excellence, we have met with no competitor for it. We saw it grind into fine meal, six bushels of unshucked corn in fifteen minutes, and we have no doubt that it will easily grind fifteen bushels an hour, and give the horses several breathing spells in that time. Sheaf oats, with corn, are rapidly converted into a fine meal by it, and the oil cake, so valuable to all fattening animals, is ground by it into a fine meal and intimately mixed with the other food. This alone is a convenience of great moment, but to be estimated properly only by those who have used the oil cake in the common way, and who consequently know the difficulties attendant on its use. No man should undertake the fattening of cattle without the oil meal, if he can procure it.

There is another convenience in this crusher scarcely less important, if any, than those we have named. It makes not only what Mr. Rowe calls, in his circular, a fair article of meal, but, Mr. Graham assures us, a superior meal to any he has been able to get at the good mills in his neighborhood. The great inconvenience under which many wealthy farmers labor in getting corn ground into meal, makes this property of Rowe's crusher very valuable. We know of farmers who sometimes travel for their meal sixty miles, and we know of one in the county who travelled, from mill to mill, to get his corn ground, until he went one hundred and ten miles.

In commending this machine to the favorable notice of our agricultural friends, we do not rely alone on our own knowledge of its performances, though we know it does all we have said of its work. The two brothers of the Hon. E. H. Foster, United States Senator from Tennessee, have used these crushers several years. G. W. Foster says he considers "the machine a great acquisition, as regards convenience and economy in preparing food for man and beast. Its great recommendations are strength, durability and simplicity. The simplest negro above idiocy can attend to it. The mill being of *chill cast iron*, will last an age; it will not cost five dollars a year to keep it in order."

Benj. F. Foster says: "He has never sent for meal to any mill since he has had this crusher. It makes not only good meal, but also large and fine hominy. No mill could supply a family with better bread stuffs. The crushed shuck, cob and corn is the best food for cattle, sheep, &c., without any preparation, but the meal should be moistened with water for working horses. Thinks the *shucked corn*, crushed, best for hogs."

Isaac Franklin has four of these mills in operation—one in Tennessee and three in Louisiana; and has ordered another in the latter State. He says: "It is the very best mill for the farmer and planter that has been introduced. The most stupid negro can manage them and cannot put them out of order. The food prepared by the crusher from unshucked corn is the best for oxen, mules and horses ever tried. The saving is considerable."

Dr. John L. Hadley, of Nashville, speaks in the same terms of the machine, of the corn meal, and of the crushed provender for animals. He has been using one of these machines for two years.

Mr. Hough, the mail contractor between here and Nashville, says, "he has had one in use two years almost constantly, and feeds his stock and large stable of stage horses nearly altogether with the crushed food, and is much pleased with the food thus prepared. No mill can surpass this for stock purposes. The meal is excellent. He believes one of these mills will run fifty years and not cost ten dollars."

Hynes & Craighead say, "They use on their plantation in Iberville parish, La., about one hundred mules and horses, and twenty or thirty oxen, which are almost in constant use. They find that their work stock are much healthier, and are capable of performing more service since they have used the crushed food. Without having made an exact estimate, they confidently believe they save from six to eight hundred dollars annually in the quantity of food used; and in the life of the stock. They formerly lost from six to eight horses and mules annually, but since using the crushed food they have not lost half that number."

From the South Carolina Temperance Advocate.

CORN.

There is no subject in agriculture that is more particularly interesting to us than the cultivation of Indian corn. In the first place it is the national crop; in the second, it bears with it a spice of romance, as being intimately connected with that race upon whom only the sacred hand of antiquity has yet impressed the stamp of poetry in this new world; but, thirdly and chiefly, because it is believed to be the most valuable vegetable growth, take it all in all, cultivated by the hand of man. I do not believe either that our savage predecessors, or our tobacco making ancestors, ever brought the cultivation of this noble vegetable to perfection. I am very sure that the system of neither the one nor the other was of the charrcter best adapted to the present state of our soil. Neglected, as to a certain extent this valuable crop now is, still, in point of profit, it need not shrink from a comparison with either of its haughty rivals, wheat or tobacco. Facts and experience, which settle the claims of high and low, will prove the corn growing to be as independent and prosperous as any other interest in the state. But it is my settled conviction, that a thorough examination into its nature and character, would induce an improvement in its cultivation, that would place this vegetable of indigenous growth upon a much more elevated position than it even now occupies. It is very true that thousands of intelligent farmers have been for hundreds of years cultivating this simple crop, and it would seem wonderful that there should be any thing yet to learn about it; but that no fixed principles have been as yet established, is vouched by the fact that there are still as many opinions about the simplest points in its management as there are different cultivators. That this variety of opinion exists, arises, I believe, from the fact, that until the late establishment of agricultural papers, men ploughed, sowed, and reaped, without thinking at all; at any rate, without receiving from each other, the advantages of their mutual observations. Until within the last 10 or 12 years, the darkness of the middle ages covered the agricultural history of America. Indeed, it was not until our exhausted soils forced us to bring mind to the assistance of matter, that our farmers began to think at all, and it was not until the general establishment of a medium of communication, that any thing but the wildest guesses, founded upon the loosest facts, occupied the cultivators of the earth. Mortifying as this picture of ignorance may be to many of your older readers, it is nevertheless true, and when they reflect, how they themselves were in former days immersed, soul and body, in *politics*, they will be forced to concede that the science of agriculture found little space in the minds of their contemporaries.

But, thanks to the good sense of our deep thinking, practical people, as the stern necessity of an exhausted soil demanded a different course of conduct, they have lately begun to investigate the secrets of the great business in which they are employed, and hence it is, tha though we have been cultivating corn for hundreds of years, we are now just upon the threshhold of discovery with respect to its nature and character.

These remarks, which, I hope, if not very flattering, will not prove very tedious, have been elicited by reading an excellent essay on the subject, in the "Southern Agriculturist," from the pen of Dr. L. R. Sams, of South Carolina.

Dr. Sams, as the result of several investigations upon the roots of corn, found them to consist chiefly of perpendicular roots, from which numerous smaller ones proceeded horizontally. The depth, number and proportion of the perpendicular roots, the Doctor found to depend very much upon the nature of the soil in which they grew. In a very light, sandy soil, incumbent on a loose subsoil, he found an average of twenty-five perpendicular roots, from three and a half to four feet long. The size and extent of the lateral roots he found to be dependent upon the moisture of the surface soils. In a poor soil, of a dry season, they did not exceed two or three inches in length, while many were much shorter; on the other hand, in a rich moist soil, these lateral roots were very much increased, not only in numbers, but in all their dimensions, a large proportion of them extending from one to two feet or more from the stalk.

On a close, heavy soil, based on a stiff subsoil, the perpendicular roots were found more numerous, but shorter, reaching an average depth of only two feet. The horizontal roots, though of smaller diameter than the perpendicular, were so much more developed than in the former case, especially when favored by a moist and mellow soil, as to traverse and occupy the entire intervals (a space of five feet) between the rows.

The practical deductions that Dr. Sams draws from these facts, are, that if the soil is made rich and mellow to a considerable depth, the perpendicular roots will naturally penetrate to that depth, and as he found that the extension of the said roots along the surface was chiefly a substitute of nature for the obstruction of the perpendicular roots, he concludes, that whenever free passage is afforded the latter through rich ground, that this plant will be furnished by these means with food and moisture, even during a drought; when the lateral or surface roots that would otherwise supply their place, would be entirely parched and killed. Again, where a free descent is afforded through a mellow soil, the roots will be found almost wholly within a circle of two feet, of which the stalk is the centre; consequently, present economy would recommend the application of manure within that space. On the contrary, where, from the nature of the subsoil, the support is derived from the horizontal roots, the application of manure in the hill would fail to furnish the roots that had extended beyond its influence with their food at the most critical period of the plant, viz: the filling of the ear. Firing, Dr. Sams considers as nothing more than a failure of a supply of food and moisture to this most succulent and sappy of the vegetable tribe; and close planting leads to this fatal consequence, only because, in our usual mode of cultivation, the plant is dependent for a supply of food and moisture on its lateral roots, which can only find a sufficient supply for one stalk within a given space.

One thing is certain, that very large crops can only be obtained by close planting, and it is a great desideratum to know how that can be effected without the danger of firing that usually attends in this region.

It is only by a strict examination into facts with all their attendant circumstances, such as the world is indebted to Sams for, that any correct or philosophical conclusion can be arrived at. He may possibly have erred in the inferences he has drawn, but the agricultural community are at least indebted to him for the communication of the interesting facts he observed.

Yours, with the best wishes for the success of your useful and practical paper.

A Corn Grower.

PLANTING OF PEACH STONES

The annexed extracts are from a letter in the Massachusetts Ploughman, from Mr. J. Bartlett, of Quincy, Illinois:

"I should plant the stones not more than six inches apart, and transplant them when two or three inches high with a trowel, taking care to cut off the tap root two or three inches under the ground. By this means, you will be sure to have good roots and luxuriant growth; your trees will be large enough to bud the first season if your soil be suitable. If a person can obtain stones from a tree that is naturally of good quality, it is better to plant such and not depend upon budding; your trees will be much more durable raised from the stone, than those that are budded or inoculated. Many people have expressed a doubt as it regards the certainty of procuring the same kind of peach from the tree raised from the stone as the parent tree produced, even when the parent tree was natural. I think there is no doubt of the fact that a peach stone from a natural tree will produce the same fruit as the parent tree. I feel as sure of the result, as I should were I to plant a yellow kernel of corn of raising yellow.

"But no reliance can be placed upon the produce of budded trees; the seed does not inherit the qualities of the bud, but of the original stock or root, and consequently you cannot know what your fruit will be until the tree produces fruit, and then it will be too late to bud with good success. In some instances, I have had good success with budding trees four or five years old, but they are very apt to throw out gum where the incision is made in the bark, and that kills the bud or prevents it from adhering to the wood."

CORNSTALK SUGAR.

The following is an extract from the report of the committee on maple and cornstalk sugar, at the New York State Agricultural Fair in 1843:

"The committee have great pleasure in stating that Mr. M. Adams, of Ogden, in Monroe county, has gone into the experiment of manufacturing sugar of cornstalks; and for one acre of the 'eight-rowed yellow northern corn,' he has constructed an iron mill for crushing the stalk and expressing the juice, which answers the purpose admirably."

"Mr. Adams has, however, already made about four hundred weight of sugar, a sample of which he has submitted to your committee, and which, though not yet clarified, appears to be of a fair quality, capable of equalling the best of sugar made from the cane. The stalks still on the ground, he thinks, will make four hundred weight more sugar; but had it not been for the excessive drought which has prevailed in that section of the country, he is satisfied that the acre planted and experimented upon by him would have produced one thousand weight of sugar, which was the rate yielded by two rods of the land, which he measured off, the proceeds of which he worked up by itself."

From the American Farmer.

RESTORATION OF WORN-OUT LANDS.

Some time since, we published an account of the astonishing improvement of Dr. Noble, of Philadelphia, on a worn-out farm of his in Delaware, which he had bought at $15 per acre, and so fertilized in a short period as to produce upwards of 47 bushels of wheat per acre. In inserting that account, we expressed the hope that the Dr. would favor the public with a particular account of the *modus operandi* pursued by him, in order that the Agricultural public might be benefitted. Some friend of the Dr. has answered our inquiries in the annexed article, from the Farmer's Cabinet, but we regret that he had not been more particular:

Worn-out Lands.—In the American Farmer, of December 27th, appeared an extract from a communication by John Jones, of Wheatland, to the Farmers' Cabinet, in which he makes allusion to the astonishing effects brought about in the renovation of worn-out lands in Delaware, by Dr. Noble, of Philadelphia. On land which cost but $15 per acre, and produced but five bushels of wheat three years ago, by the application of eight loads of manure, costing—freight included—less than $1,50 per load, the Doctor has raised forty-seven bushels of wheat from 1 acre, and from the remainder rather less, the average being an enormous increase over the produce of former years. The editor of the American Farmer expresses an "intense desire" to learn the secret by which the Doctor has been enabled, at the small expense of less than $12 per acre, to effect such astonishing results.

We would inform him, there is no secret whatever in the method pursued, but such as any farmer might discover for himself, if he would but take the trouble to read some of the numerous works upon the application of Chemistry to Agriculture, lately published. Knowing, by chemical analysis or examination, the composition of the grain and straw of wheat, and that of the soil, it was an easy matter to apply those materials which were needed, in order to produce a healthy and vigorous growth. He prescribed for his wheat and soil as he would for a patient, and with equal success; health and strength have been restored to the suffering subject.

Now, as to the sources of the manure which he has made use of, we will say a word; it is in the power of every farmer, near large cities, to procure the materials which are needed to enrich the soil.

The Doctor formed a compost obtained from various sources, consisting of the refuse of tanners', soap boiling establishments, &c., in short, of such animal and vegetable substances as contain soluble salts, or which can be made subservient to the growth of plants. In the selection of these substances, he was guided by their composition as made known by chemical analysis. "Give," says the rational agriculturist, "to one plant such substances as are necessary for its developement, but spare those which are not requisite for the production of other plants which require them."

"An emphatical," or quack system "of agriculture, has administered the same kind of manures to all plants, or where a selection has been made, it has not been based upon a knowledge of their peculiar composition." The phosphate of soda or lime, the silicate of potash, and sulphate of ammonia, or other salts containing these in other combinations, are necessary for the production of wheat; these have been supplied by the Doctor, and why should we be astonished at the results which have followed their application? He has adopted the scientific method of manuring, and if his knowledge of the composition of the soil and wants of the crop was exact, and his conclusions correctly drawn, he could not err in the application of his manures. His is indeed a triumph of science over the old-fashioned, uncertain, and empirical mode of farming; here is an example worthy the attention of every farmer, and especially should it be considered by those whom prejudice has so blinded that they cannot perceive the vast benefits arising from the judicious application of scientific knowledge to agriculture. It is indeed "creditable to the Doctor as a scientific farmer," we hail him as a benefactor, and desire that he may persevere in that path of usefulness in which he has found both pleasure and profit. J. L. S.

Philadelphia, Second month 6th, 1844.

From the Southern Planter.

SALT—AN INJURY TO STOCK.

In conversation with a very practical farmer, who has been successful in raising stock, (I refer to Dr. Venable of Mecklenburg,—I know he will excuse the liberty of giving him as authority, for what follows,) I was a little surprised to hear from him, that if he was requested to give a recipe for the most effectual method of gradually destroying a good flock of sheep, he would say—"*Salt them freely from the 1st of November or December to the 1st of April.*" He thinks also, that it is very injurious to cattle, to salt them during the winter months. His reason for this opinion is, that the use of salt creates an unnatural thirst, and the introduction of cold water into the stomach of the animal, (especially of sheep,) is followed by many of the "ills that brutes are heir to." I am very sure, Mr. Editor, that the Doctor is very willing, and would desire to hear any objections and reasons in opposition to his theory, and I hope you, or some of your correspondents, will give their "notions" on this subject. The theory is supported, (the Doctor tells me,) by facts—a very satisfactory mode of argument. Those of his neighbors who have made free use of salt in winter have lost their sheep and cattle: he and others of his neighbors have been very successful in rearing them.

The Doctor, however, advocates the free and frequent use of salt for cattle, from 1st April to 1st November. He gives it three times a week. He does not give the salt alone. He makes use of the following recipe, viz:

Mix 4 bushels of clay, 2 bushels of salt, 2 lbs. of sulphur, and 2 lbs. of saltpetre: he gives the mixture in ample quantities, and sometimes makes up the mixture in cakes, and puts it about his gullies and galls—thus inviting the cattle to frequent such spots and enrich the soil (on which he has scattered herdsgrass seed) by their "deposites." Junior.

December 6, 1843.

We have frequently noticed objections, in the northern papers, to curing hay with salt, on account of its injurious effects upon the animals to which it was fed, arising from the unnatural excess of salt with which they were thereby drugged. But we had imagined that if a plentiful supply of salt were placed at the disposal of the animal, instinct would direct him as to the quantity required for his system.

Age of the Sheep.—The age of sheep may be known by examining the front teeth. They are eight in number, and appear, during the first year, all of a size. In the second year, the two middle ones fall out, and their place is supplied by two new teeth, which are easily distinguished by being of a much larger size. In the third year, two other small teeth, one from each side, drop out and are replaced by two large ones: so that there are now four large teeth in the middle, and two pointed ones on each side. In the fourth year, the large teeth are six in number, and only two small ones remain, one at each end of the range. In the fifth year, the remaining small teeth are lost, and the whole front teeth are large. In the sixth year, the whole begin to be worn; and in the seventh, and sometimes sooner, some fall out or are broken.

Warts on Cows' Teats.—Mr. Jonathan Perry, of Dover, tells us that lamp oil will kill warts on cows—apply it several days in succession. If other farmers find this effectual, they will oblige by sending additional testimony.

Mass. Plough.

From the Practical Farmer.

AGRICULTURE AS A SCIENCE.

All knowledge is founded on experience: in the infancy of any art, experience is confined, and knowledge is limited, to a few particulars; but as arts are improved and extended, a great number of facts become known, and the generalization of these, or the arrangement of them, according to some leading principles, constitute the theory laws, or science of an art.

Agriculture, in common with other arts, may be practiced without any knowledge of its theory; that is, established practices may be imitated; but in this case it must remain stationary. The mere routine practitioner cannot advance beyond the limits of his own particular experience, and neither derive instruction from such accidents as are favorable to his object, nor guard against a recurrence of such as are unfavorable. He can have no resource for unseen events but ordinary expedients, while the man of science resorts to general principles— refers events to their true causes, and adopts his measures to meet every case.

The object of the art of agriculture is to increase the quantity and improve the quality of such animal and vegetable productions of the earth as are used by civilized man, and the object of the agriculturist is to do this with the least expenditure of means—in other words, profit. The result of the experience of mankind as to other objects, may be conveyed to an inquiring mind in two ways: he may be instructed in the practical operation of the arts, and their theory, or the reasons on which they are founded, laid down and explained to him as he goes along; or he may first be instructed in general principles, and then in the practices which flow from them.

The former mode is the natural and actual mode in which every art is acquired by such as have no recourse to books, and may be compared to the natural mode of acquiring a language without a knowledge of its grammar. The latter mode is by much the more correct and effectual, and is calculated to enable an instructed agriculturist to proceed with the same kind of confidence and satisfaction in his practice, that a grammarian does in the use of language.

GRAFTING GRAPE VINES.

The late Mr. N. Herbement, of South Carolina, a successful cultivator of grape vines, after referring to the usual modes of grafting fruit trees, says:

"But let vines be grafted in this manner, unless the operator knows the particular requisite for the vine, and the probability is that he will scarcely succeed once in five hundred trials. The mode of grafting, which I practice usually, and which is attended with no difficulty, and very seldom fails, is as follows:—All I do, is to take away the earth round the vine, to the depth of four or five inches; saw it off about two or three inches below the surface of the ground; split it with a knife or chisel; and having tapered the lower end of the scion in the shape of a wedge, insert it in the cleft stock so as to make the bark of both coincide, (which is perhaps not necessary with the vine;) tie it with any kind of string, merely to keep the scion in its place; return the earth to its place, so as to leave only one bud of the graft above the ground, and the other just below the surface, and it is done."

TO YOUNG MEN—TRUTH WELL SPOKEN.

We commend the following well-timed remarks of the editor of the New-York Tribune, to the special attention of those young men in the country who feel inclined to murmur at their lot, and to envy young men in cities their imaginary advantages.—*Gen. Farmer.*

It is a sore evil that labor, so essential to health, vigor, and virtue, is generally regarded with aversion. Even those who boast that they live by straight-forward hard work, are almost uniformly seeking to escape from their condition,

Even the substantial, thrifty farmer, whose life is, or might be, among the happiest, is apt to train his darling son for a profession or put him in a store. He laudably wishes to put him forward in the world, but he does not think that half the time and expense bestowed in making him an average lawyer, or doctor, would suffice to make him an eminently intelligent and scientific farmer—a model and blessing to the whole country. Why will not our thrifty farmers think of this? The world is surfeited with middling lawyers and doctors—the gorge even of Iowa rises at the prospect of a new batch of either; of tolerable clergyman there is certainly no lack, as the multitudes without societies bear witness, and yet here is the oldest, the most essential and noblest of employments, on which the full blaze of science has hardly yet poured, and which is to-day making more rapid strides, and affords a more prominent field for intellectual power than any other, comparatively shunned and neglected. Of good, thoroughly educated, at once scientific and practical farmers, there is nowhere a super-abundance. Every where there is need of this class, to introduce new processes and improve old ones, to naturalize and bring to perfection the plants, grains, fruits, &c. we still import from abroad when we might better produce them at home—to introduce a proper rotation and diversification of crops—to prove and teach how to produce profitably the most grain to the acre—in short, to make agriculture the pleasing, attractive, ennobling pursuit it was originally intended to be. There is no broader field of usefulness—no surer road to honorable eminence. The time will come when, of the men of the last generation, Arthur Young will be more widely honored than Napoleon. But while the true farmer should be the most thoroughly educated and well informed men in the country, there are many of our old farmers even, who will cheerfully spend a thousand dollars to qualify one son for a profession, yet grudge a hundred each to educate the three or four less favored who are to be farmers. There are farmers who cultivate hundreds of acres and never look into a book on agriculture, though they would not countenance a doctor or clergyman who studied no works on medicine or theology. What a world of mistakes and inconsistencies is displayed all around us!

There are thousands in all our cities who are well employed and in good circumstances; we say, let these continue, if they are content, and feel certain that the world is better in their daily doings. There are other tens of thousands who *must* stay here, as things are; having no means to get elsewhere, no skill in any arts but those peculiar to city life, and a very limited knowledge; these must stay, unless something should transpire out of the common course of events. There are other tens of thousands annually arriving from Europe, who, however valuable acquisitions to the country, must contribute to glut the market and depress the price of labor of all kinds in our city—some of these must remain here till they can obtain means and knowledge to go elsewhere. But for young men of our own happier agricultural districts to crowd into the great cities or into villages, in search of clerkships and that like, is madness—inhumanity to the destitute—moral suicide. While nine-tenths of the States are a waste wilderness, and all our marts of trade overflow with eager seekers for employment, let all escape from cities who can, and all who have opportunities to labor and live in the country, resolve to stay there.

From the Tennessee Agriculturist.

TO YOUNG LADIES.

Having formerly addressed young ladies on gardening, &c., I take the liberty of presenting them another subject, in which I feel a deeper interest, and which is to them of far more importance. The Christian Religion is my theme now, and I am particularly anxious to engage the young in the study of this noble science. I call it a science, because it can be learned only by study.

It is not something we can pick up in this place or that—it will not come in a still small voice, or run over us like a shock of electricity, paralysing the faculties and rendering us incapable of sensible thought or action. No, as I said before, it is a noble and beautiful science, to attain a correct knowledge of which, requires the exercise of the best powers of the soul—the most earnest desires of the heart. I speak to the young, because it is in the morning of life we should commence the acquisition of this knowledge, should lay up the rich stores which will make us wise unto salvation.

I know the lightness, the gaiety, peculiar to youth, causes the Christian Religion to be regarded as something dull and gloomy—something that is calculated to lessen its happiness; but let me tell you, that it forbids nothing that is not ultimately injurious. Does it forbid the amusements in which the thoughtless votaries of pleasure engage with so much eagerness, and which often cause their ruin, temporal and eternal? If it does, it is because they are hurtful. They may give a transient glow of pleasure for the present, but leave a sting behind. I have seen the young, the gay and the beautiful, die, without hope and without God in the world, and have heard them lament, with their last breath, that their parents had not restrained them in their gay career—had not taught them to live for *eternity* as well as for time.

Had they, in early life, been taught to regulate their lives and conduct by the Christian Religion, how much anguish would have been spared them in that last sad hour, when death feels about the heart with his icy fingers, blasting the bright hopes and stopping the warm pulse of life.

The Religion of Christ is the preservative principle. It is the salt of the earth. Without it, the character of woman, old or young, is defective. When well understood and practiced, it gives a dignity and propriety of conduct, a softness and gentleness of disposition, that renders youth most engaging, most lovely. A woman, who is uninfluenced by the pure principles of the Gospel, is a branch from which emanates no verdure, for the principle of life is wanting. I have seen some who would even sneer at the sacred volume—at the world's best friend, the only hope of man. If you have ever spoken lightly of, or treated with scorn, the Gospel of the Saviour, let me persuade you, for your own sake, from the consideration that the Christian Religion has done so much for woman, to refrain from what appears so odious. Willis, speaking on this subject, makes some beautiful and suitable remarks:

> "Oh, what is woman, what her smile,
> Her lip of love, her eye of light—
> What is she, if she still revile
> The lowly Jesus? Love may write
> His name upon her marble brow,
> And linger in her curls of jet:
> The young spring flowers may scarcely bow
> Beneath her step—and yet and yet,
> She is, she is, and still must be,
> A lighter thing than vanity.

I have to leave off at present; but, nothing preventing, I wish to speak to you of the importance of becoming christians early, that you may be educated, that you may be trained for the society of Heaven. You know that here we have to be trained for good society before we can enjoy it. So it is with regard to the future life. Were we placed among the pure spirits of the Holy Land, we would be miserable, unless previously prepared to participate in their enjoyments. At some future time, I will speak to you of this important preparation. LUCY.

CURE FOR THE BLOODY MURRAIN.—A subscriber called on us a few days since, to say that cattle may be cured of this disease, by giving a table spoonful of Mandrake root pulverised, to each animal. This, he says, will almost always effect a cure, but may be repeated in half the quantity after an hour, if the first does not answer.

N. Y. Central Farmer.

From the Boston Cultivator.

COWS HOLDING UP THEIR MILK.

A farmer observes that he was troubled with a cow holding up her milk, and he could devise no means to remedy the evil; when his son, only 9 years old, took the management of the cow, in this respect, and succeeded well. This son was afterwards at his uncle's, who had the same trouble, and feared that he should lose his cow, as she had not given down any milk for several days; the boy said that he could milk her. He went to work performing the operation precisely as though the cow gave down her milk, though for some time she gave none; he still persevered, and after some time the milk flowed freely, and he obtained nearly two pails full.

This shows that mildness and steady perseverance is necessary in this business. Some persons become fretful if they cannot succeed in milking at once, and then abuse the cow for her obstinacy, instead of persevering, and succeeding as they might in many cases. It is doubtless most natural and easy for a cow to give down her milk, and when she holds it up she puts herself under a restraint, and this requires a constant exertion, of which she will become tired after a while, if the milker perseveres. These are our views, and we advise those who are so unfortunate as to have a case of this kind, to try the effect of perseverance, if necessary.

PEACH STONES.

A writer in the Massachusetts Ploughman, says:

"Deposit the stones, after being taken from the peach, in sand or dirt; put them in the ground, slightly covered, in the fall. As for the cotton-bag in which to keep them under ground, I have never tried it, or any other covering but the ground itself. Take up the stones early in the spring, crack them and plant immediately the meats or pits. In a week or ten days, they will all be up, without fail, just as certain as so many peas, or kernels of corn."

Another writer in the same paper thus states his practice:

"My manner of propagating from the stone, is to gather the stones soon after the peach harvest, before they become extremely dry, and scatter them upon the surface of the ground in my garden, there to remain until the garden is plowed the next spring; when, in the course of a few weeks, or nearly as soon as other vegetation comes, they will be seen coming up pretty abundantly. These I transplant soon after they spring up, to some convenient place of cultivation, where they remain one or two years, just as purchasers prefer."

This writer states that he has planted, for many generations, the seed of two varieties of the peach, and that he was not able to perceive the slightest variation from the original fruit. The two varieties were planted together.

From the Boston Cultivator.

BEES.

Bee hives should be shaded until the snow is off, and the weather so warm that the bees can go out without injury from the cold. When the sun shines on a hive, it produces a heat that invites the bees out, when it is so cold that they become chilled, and fall upon the snow or cold ground, and cannot recover. In this way thousands are lost. We should as soon think of allowing calves, lambs, chickens, ducks, &c., to go out and perish in cold storms, as to allow the destruction of bees for want of care. When the hives are in the shade, and it is rather dark around them, the bees will not be invited out till it is so warm that they can generally return in safety. Besides the great evil we have named, the bees on going out discharge the contents of their stomachs, as may be seen around the hive, and which they never do in the hive; consequently they must fill them again, and thus cause a needless consumption of food.

From the Southern Planter.

IMPROVEMENT OF THE SOIL AND OF THE MIND.

The late excellent Judge Buel, has left us much information upon the "improvement of the soil and of the mind." If I forget not, he generally had an essay on the improvement of the mind, for the benefit of the rising generation, both male and female. It is evident to every observing man, that the improvement of the soil and the mind must go together. Their influence acts reciprocally on each other. The wisest of men, Solomon, says, "I went by the field of the slothful, and by the vineyard of the man *void of understanding;* and lo, it was all grown over with thorns, and nettles had covered the face thereof, and the stone wall thereof was broken down. Then I saw, and considered it well; I looked upon it and received instruction. Yet a little sleep, a little slumber, a little folding of the hands to sleep: so shall thy poverty come as one that travaileth; and thy want as an armed man," (a sentinel, I suppose, who dare not leave his post until relieved.) See Book of Proverbs, xxiv. 30-34.

Again he says, "Seest thou a man diligent in his business? He shall stand before kings; he shall not stand before mean men."

All nature is progressive, and man, the lord of this lower world, by Divine appointment, is commanded to grow in favor and knowledge of his Lord and Saviour, Jesus Christ This is done, by the works of creation, and revelation, understood and obeyed. The Author of all nature has given a constitution for the physical universe, for his creature man, and for Christ's Church. These are as immutable as his throne, and admit of no improvement or amendments. Progressiveness is an essential attribute of all beings except the Deity—its absence implies either a state of absolute perfection, or an insusceptibility to any improvement. The first state is applicable to the Divine Being alone, and the second applies not to man, physically, politically, intellectually, or religiously, considered. Progressive improvement—constant, uninterrupted and perpetual, entered into the design of God, in the formation of all organized bodies, whether animate or inanimate, physical or mental. The vegetable, animal, and intellectual world, when uninterrupted by the perversions of art, afford constant, sensible demonstrations of the universality of this principle. The infant plant, in its regular and rapid advances to a state of maturity—the infant man passing gradually and regularly from the cradle upwards, through the gradations of boyhood, and manhood, to maturity of stature and texture; the infant mind, which is first limited in its capacities to the direct objects of sense, but soon acquires the art of reasoning and reflection, and continues to advance to the stature of a powerful genius, all tend to demonstrate this undeniable truth. The arts, sciences, politics, and religion, have had their infancy, and the various stages of their progress and improvement make up their whole history.

How incompatible with the design of God, are those authoritative and proscriptive creeds, political and religious, which trammel the human mind, and set those narrow bounds to investigation and research! What would be the result, should some misguided cultivator attempt to set physical bounds to his stalks of corn, before they arrive to maturity? or should some capricious or fanciful parent invent some physical contrivance to prevent the further development of his son's physical system, and apply it at the age of ten years, what would be the result? Equally absurd is it to collect the agricultural, political, or religious sentiments of any man or set of men of any age, and out of them constitute a proscriptive creed for the prevention of all further advances of light and truth: such a course would be disastrous to the peace and prosperity of society—and has been the cause of much political and religious faction, and is now rending and tearing the world to pieces. This is the fruit of bigotry and intolerance, produced by the demon of party spirit.

Demosthenes, when asked the first requisite to eloquence, replied, "action,"—when asked the second, he replied, "action,"—and the third, he still replied, "action." Industry bears the same relation to agriculture that action did to eloquence, in the estimation of the Athenian orator. With industry, the farmer may accomplish every thing—and without it, he can do nothing. Let him study the value of time. Time is his great capital, and should be well invested. The wealth of the world, its high civilization, and its magnificent improvements, have been created and finished by the labor and industry of man. The poorest soil and most unfavorable climate are scarce impediments to an industrious and energetic people. Look at Holland, reclaimed from the ocean, fenced in by her embankments and mud walls, literally a smiling garden, where once there were nothing but bogs and ocean's wave. Look at Switzerland, where an industrious and hardy people, contending against the avalanches of snow and ice, and the embankment of mountain masses of rocks, falling and crushing for miles square every thing before them, have cut the hills and mountains in terraces, and planted them with vines; according to the account of travellers, lands which before were worse than nothing, by this improvement sell for ten thousand francs per acre.

If there is one who may eat his bread at peace with God and man, it is that individual who has brought that bread out of the earth by his own industry: it is cankered by no fraud, it is stained by no blood, it is wet by no tear, but the sweat of his own brow.

I will conclude by giving you the true test of fame. The truest seeker after fame is the man who labors to make his children useful and honorable in their generation. In this way, editions of his works may go on multiplying, instead of, perhaps, sinking into oblivion with his own time.

If acceptable, I may furnish extracts of interest to your readers occasionally, upon the various duties of this life.

King & Queen.

From the Southern Planter.

BEDS—COMFORTERS—MINCE-PIES.

Mr. Printer—I don't often spend a night from home, but last July I went to see a neighbor, richer than John and I. A rain kept me there all night. They put me to sleep in a room right well aired, but in a *feather-bed!* The night was very hot, and you may be sure I suffered.

Isn't it wonderful that people should know so little about comfort, as to sleep in feather beds in summer? In all the houses I go to, some richer and some poorer than ours, I see none but feather beds. Now, I have been sleeping, winter and summer, upon a mattrass made of corn shucks, with layers of wool, and upon my word, I would not give it up, and sleep on a feather bed, for fifty dollars a year. The feathers heat you too much in warm weather, and at all times, they let the body bend so in their mushy hollows, that it is filled with aches and cramps. Dr. Mason says, (and John calls him my oracle,) that in bilious fever neighborhoods, people who sleep on mattrasses like mine, or hair mattrasses either, or nice straw beds, are a great deal less apt to have the fever, than people who sleep in feather beds. He says the feathers relax the system, make the sweat excessive and irregular, and disorder the digestive organs.—(You see I've learnt some of the Doctor's hard words.)

John went to Middlesex last summer, and says they almost sweated him to death in their feather beds. They have a fever harvest there every September. Such a mattrass as mine, any woman can make, with a little help from her husband. I made mine. One can be bought for six or eight dollars. I hear that at the Exchange Hotel, and all the most fashionable houses, they sleep only upon mattrasses.

Now, about *comforters.* There are many Virginia people, quite well off in the world, who won't buy blankets, through "economy," as they call it. There are others who can't afford to buy them; some, through real poverty, and some because they can't spare the money from their grog-shop allowance Most of these people cover their beds with *quilts.* I would almost as lieve have a sheet of iron spread over me, as one of these quilts—it is so cold and heavy. There's a philosophy about this, as there is about ripe bread. *Quilting* the bats of cotton in the quilts, with such close rows of stitches, makes it solid and compact, so that it conducts away the heat of the body. For things close-grained, or compact, are *conductors* of heat—while things that are spongy, or open, like locks of wool or cotton, are *non*-conductors of heat. Now, I can tell these frugal people how they may have coverlets for their beds, a great deal warmer, and cheaper too, than bed-quilts.

Take three pounds of cotton, carded in bats, lay them smoothly and regularly over a sheet of cotton or cheap calico; spread over them another sheet, and stitch the two sheets together by long, easy stitches, in rows at least eight or ten inches apart. The stitching is only to keep the bats in place. Bind the edges with any thing you please. You will find such a comforter warmer than three blankets. And five pounds of cotton, carded into light, loose bats, will make it too warm to sleep under, except in the coldest weather.

All clothing warms us, not by any warmth of its own, but by confining to our bodies the heat that comes out of them. The bats being so loose and spongy, make the comforter a *non-conductor* of heat. So it confines the heat to our bodies, and keeps them warm. No blankets have been on our beds for ten years, and nobody sleeps cold in our house.

Mince-pies, it is thought, can't be made toothsome without wine or brandy in them. It is not so. No pies of mine have had a drop of any intoxicating liquor for three years, yet the best judges have said, and behind my back, too, that my mince-pies were equal to any they had ever tasted. Besides, Mr. Printer, I have the comfort of knowing, that in these three years, no reformed drunkard has ever *tasted relapse and ruin* at my table, though several have eaten of my pies, and that no child or servant of ours is ever seen coming from the liquor-shop with a jug or bottle—no liquor seller can say "the Dumplings are customers" of his.

This is my

RECEIPT FOR MINCE-PIES WITHOUT WINE OR SPIRITS.

Take 4 pounds of plums, 1 pound of currant, 2 of cherries, 3 of beef suet, 4 of sugar, a fresh beef's tongue, ½ a pound of citron, 1 ounce of mace, ½ an ounce of cloves, 1 nutmeg the juice of 2 lemons, vinegar to your taste. Make mince-meat of these materials, and put it by for use. When you make pies, add syrup, or juice, or stewed apples, to make the mince-meat liquid, and some fresh apples chopped fine.

In place of citron, marmalade or preserves will do. Dorothy Dumpling.

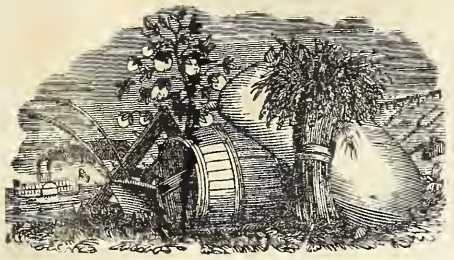
Louisa, January, 1844.

GREASE SPOTS.

A correspondent of the Southwestern Farmer, who signs "J. E. W." gives the following as a good recipe for taking grease spots out of clothing, &c.:

"Take the yolk of an egg, entirely free from the white, (be sure not to scald the egg,) and with a soft brush apply the mixture, and rub it on the spot until the grease appears removed or loose. Wash off the egg with moderately warm water, and finally rinse off the whole with clean cold water. Should not all the grease be removed, which may arise from being on a long time, or not sufficiently washed, dry and repeat the operation."

The writer of the above, says that a fine Merino shawl, which had been badly smeared with tar and grease, (gudgeon grease,) was perfectly cleaned by this process in a few minutes.



WEDNESDAY, APRIL 3, 1844.

THE BACK VOLUME.

All new subscribers who may desire it, can obtain the first volume, neatly bound in boards, at one dollar the volume.

An Apology.---The same cause which operated to delay the publication of our last number beyond its proper time, has operated upon the present. Now that our compositors have all recovered from the Measles, we hope to move on regularly, and to issue our paper on the regular day of publication.

CORRESPONDENTS—OURSELVES.

In the prosecution of our labors—in our efforts to present an Agricultural Journal acceptable to Southern planters, devoted, as it should be, to that system of agriculture best adapted to our soil, climate and productions—we had fondly hoped to have received the fostering aid of the planters generally, in the form of contributions, in which new theories should be presented, or old ones improved upon. In this, however, if we make a few honorable exceptions, we have been wholly disappointed. Why it is, we know not—indeed, we confess ourselves incompetent to render a plausible excuse for many of the warm friends of the work, who have never contributed a paragraph or a line to its pages. Why is this? Do they not feel the necessity of such contributions? It occurs to us that every reader of the paper must be struck with the almost entire absence, in our pages, of the contributions of practical men. We feel, and feel sensibly, this defect; and we know that our readers must also feel disappointed from the same cause. And yet, notwithstanding all our efforts and entreaties to our numerous friends, we have not been able to overcome their apparently positive reluctance to communicate whatever they deem of value to the great brotherhood of planters.

It is our purpose, therefore, in this article, to renew our oft repeated and urgent requests to the friends of our enterprise, to afford us some aid in this respect. We are peculiarly situated—being, with two exceptions, the only Agricultural organ in the cotton growing regions: we are necessarily, in the absence of original contributions, compelled to extract copiously from other journals, and not unfrequently matter not so well adapted as that which would, and could be afforded by our friends. Besides this, we have an additional claim upon their intellectual efforts; for they are interested to an equal, if not greater degree than ourselves, in the establishment of the most approved and enlightened system of culture: such a system results immediately in their benefit, and but indirectly for ours. It is therefore due to themselves, because of their deep interest in the subject, that they should contribute their mite to render the Cultivator not only interesting, but valuable to every reader. In proportion as it is fostered and sustained by the contributions of our own planters, in the same ratio will it increase the interest and attract the attention of discreet farmers, wherever it may be seen and read. And, in this way, it will be based upon a firm and immovable foundation, diffusing its benefits to a whole race of people, by introducing to them the results of practical operations in every department of their highly important vocation.

Does any man doubt that such will be the actual result of the publication of such a work, in the success of which a whole people are interested? Certainly not. Then, do we ask too much of our friends, when we ask them to contribute their several mites to the prosperity of the whole country, of which they are a citizen? Indeed, we but ask you to enrich yourselves, to put money into your own pockets. For, if we can but succeed in exciting sufficient interest on the subject, our paper will be well stored with matter adapted to the improvement of every department of agriculture. And, as a consequence, while one is enlightening his brethren in one branch, he will be receiving equal benefits from the suggestions of another in a different branch. Let us then hope that, for the future, we shall not again feel compelled to recur to this subject, but that, on the contrary, our friends will contribute liberally to our own, and to each other's wants.

Remedy for Botts, &c.—Our excellent friend, Gen. Grier, of Taliaferro county, has sent us the annexed recipes, which we commend to our readers. We have heretofore given that for Botts, but it is one which cannot be too often repeated, and we are gratified to have this additional testimony in support of its efficacy.

—

Raytown, Ga., April 2d, 1844.

Cure for the Grubs.—Make a strong decoction of sage tea, and drench in the usual way, will soon expel the grubs. Last summer, I had a mare that was very sick—she was up and down, rolling and tumbling; and, from the symptoms, I had just reasons to think it was the grubs—and, having heard that sage tea was a good remedy, I prepared a tea, and drenched once, and in a short time the mare was relieved. She did not lie down, and roll and tumble about, after the tea was given.

Another case.—A negro wagoner, on his way to Augusta, last fall, called at my house with a sick horse, and applied to me to do something for the horse. After looking at the horse, and inquiring of the boy about the symptoms, I was induced to believe it was the grubs, and directed the sage tea to be given, and the horse was quickly relieved. These two cases, which came under my own observation, succeeded so well under this simple mode of treatment, that it has induced me to make it more public.

I have just conversed with a stage contractor, who recommends sage leaves to be put in the troughs occasionally, as a preventive for the grubs.

—

To kill Lice on Horses and Cattle.—Make a strong sassafras tea, or red pepper tea, or a mixture of both is preferable, with a reasonable portion of lard, and rub or wash the animal with it every two or three days. It will kill the lice and destroy the nits as fast as they hatch; and, by a few washings, the animal will soon be rid of the lice: it is a sure and safe remedy.

—

To kill Lice on Hogs.—Cut up a few pods of red pepper in small pieces, and fry them in lard until they change their color, then mix it with tar and a small quantity of spirits of turpentine, and rub or smear it on the affected parts, and along the back and sides. It will effectually drive away the lice.

Death of Willis Gaylord.—The Albany Argus announces the death of Willis Gaylord, Esq., formerly one of the editors of the Genesee Farmer, and since the death of Judge Buel, senior editor of the "Cultivator." He died at his residence, Limerock Farm, on the 27th instant, after an illness of only thirty-three hours. He was a most estimable citizen, and one of the ablest agricultural writers in the United States.

VALUE OF AGRICULTURAL PAPERS.

The following extract of a letter, from Thos. Affleck, Esq., of Mississippi, is so pertinent on the subject of the value of Agricultural papers, that we cannot forego the pleasure of laying it before our readers, with the hope that it may excite among some of them a disposition to make trial of some of the various suggestions which are contained in our columns, and thereby test the truth of the value of Agricultural papers.

"I perceive that you do me the honor to republish some short articles of mine. Gladly would I do more towards exciting in my brother planters a desire to improve in their calling, were it in my power; but I find my leisure for writing much curtailed—and, moreover, doubt very much their willingness to be taught by as young a planter as myself. I doubt, too, my own capability of teaching; but, when I pick up, or acquire, by experiment, any thing that I consider to be an improvement, I am anxious to have others test it, and to save them the labor and time which I had to bestow in acquiring it. And this is the great advantage of Agricultural papers—that they form a record of such things, and a cheap and ready vehicle for disseminating information, which it has taken perhaps a lifetime to acquire. Here, for instance, is one item which may be before hundreds in a very short time, through the medium of your paper—a cure for a troublesome disease in the horse, *swinney* or *swayney*—which, otherwise, they might never know. *I have not tried the remedy*, but I had it from a practical man, who assured me that he had himself effected at least *eight* perfect cures by it. He takes a quantity of common red *earth-worms*, puts them over the fire in a pan, with just sufficient water to keep them from sticking to the pan or scorching, and allow them to simmer there until *they melt into an oil-like substance*, which is bottled up for use. Rubbing the shoulder with this oil two or three times a day, for a few days, will, he assures me, effect a perfect cure.

"Here is another simple affair which, had I known it this last spring, would have saved me a world of lost labor, *and of rail timber*. The only rail timber I have, on one plantation, is blue or yellow poplar, (Liriodendron Tulipefera,) enormously large trees, which I find great difficulty in opening. The stoutest hand, with a *maul* as heavy as he can handle, can make no impression on many of them—the maul bouncing from the wedge or glut, without *entering it* an hair's breadth. A weight or power, greater than one hand can manage or exert, is requisite to overcome the resistance. I was recently complaining, to an old gentleman, of the difficulty; and how much I regretted to see fine large timber trees scattered about, which I could not use; and which, in a growth of magnolia, holly, mulberry, &c., were of great value to me. He at once suggested a remedy, "which he had always practsied!" He takes a hickory, dogwood, or other hard wood stick, say six or eight feet long, and seven or eight inches through—squares one end of it for striking with, bores an inch and a half, or two inch augur hole, entirely through, within eighteen inches or two feet of each end; through these runs two pieces of a stout grape vine, so that the stick can be lifted by four hands, and swung as a *battering-ram*. With a very few blows of this effective *maul* on the glut, the largest log can be opened; and, when quartered, can be readily worked up into rails.

"Now here we have another of the advantages of Agricultural papers. I instance myself again. I felt satisfied, when I first settled in the South, that a ruinous practice was pursued in the culture of Cotton, and was exceedingly desirous of making a change. I had so many old planters tell me, both by their example and their precept, that the only way to make Cotton was to plow shallow, and put Cotton after Cotton on the same land for twenty years in succession; that manure would not pay for the trouble and labor necessary to apply it; and that if *I wanted the Cotton*, I must leave plenty of plants in the ground—that I almost feared to attempt any great change, and would have gone on experimenting in a small way for some years, had I not seen those excellent and able letters of Dr. N. B. Cloud, in the Albany Cultivator. These at once determined me to give greater distance to my Cotton, and last year I reaped the reward. Of the absolute necessity for manure, deep plowing, surface culture and a rotation of crops, in Cotton growing, as in every thing else, I needed nothing to convince me.

"You will observe that I have proposed a sweepstakes' crop of five acres—five dollars entry. Who of your readers will join us? It is open to all. Will Dr. Cloud? I should be highly gratified by his doing so."

From the Maine Cultivator.

COB MEAL.

Messrs. Editors:—I noticed some time since an article in your paper—editorial, I think—in which it was urged upon farmers to *grind their cobs*, as the meal was valuable for many purposes on the farm—particularly for poultry, hogs and stock.

On the strength of this suggestion, I "acted," and can now assure you, so well satisfied am I with the result, that my cobs will never, as heretofore, be "*uselessly thrown away*." As I grind my cobs with the corn, I cannot speak definitely as to the value of corn meal when used in its pure and unmixed state, but I am satisfied that here is a very important saving attained by economizing cobs in the manner you direct. I have, during the last three months, fed corn and cobs to my horses, cattle, hogs, and calves, and as I have a large stock this winter, and have, thus far fed them wholly on the products of my farm, the saving to me, from this simple suggestion, has, I assure you, been of no small value as regards the *purse*.

Yours, Economist.

Conundrum.—Why are many modern ladies like the lilies of the field?

Strange mode of curing a Vicious Horse.—I have seen vicious horses in Egypt cured of the habit of biting, by presenting to them, while in the act of doing so, a leg of mutton just taken from the fire: the pain which a horse feels in biting through the hot meat, causes it, after a few lessons, to abandon the vicious habit.

Burckhardt.

Remedy for Lice in Cattle.—Fine dry sand, when scattered on the back, neck and sides of animals, is an effectual remedy against these vermin. A friend of ours observes that he collects dry sand and puts it in a tub or box in the barn, and occasionally applies it during the winter, by sifting or strewing it over the body of the creature, with complete success in ridding it of its troublesome guest.

HYMN TO THE FLOWERS.

by horace smith.

Day-stars! that ope your eyes with man, to twinkle,
From rainbow galaxies of earth's creation,
And dew-drops on her lonely altars sprinkle,
As a libation—

Ye matin worshippers! who, bending lowly,
Before th' uprisen sun, God's lidless eye,
Throw from your chalices a swee and holy
Incense on high!

Ye bright Mosaics! tha: with storied beauty,
The floor of Nature's temple tesselate,
What num'rous emblems of instructive duty,
Your forms create!

'Neath clustered bowers, each floral bell that swinge th
And tolls its perfume on the passing air,
Makes Sabbath in the fields, and ever ringeth,
A call to prayer!

Not to the domes, where crumbling arch and column,
Attest the feebleness of mortal hand;
But to that fane, most catholic and solemn,
Which God hath plann'd—

To that cathedral. boundless as our wonder,
Whose quenchless lamps the sun and moon supply,
Its choir the wind and waves—its organ thunder,
Its dome the sky!

There, as in solitude and shade I wander,
Through the green aisles, or stretched upon the sod,
Awed by the silence, reverently ponder
The ways of God—

Your voiceless lips, O flowers, are living preachers,
Each cup a pulpit, every leaf a book,
Supplying to my fancy numerous teachers,
From loneliest nook.

Floral apostles! that in dewy splendor,
"Weep without woe, and blush without a crime,"
Oh! may I deeply learn, and ne'er surrender
Your lore sublime!

"Thou wert not, Solomon, in all thy glory,
Arrayed," the lilies cry, "in robes like ours;
How vain your grandeur! ah! how transitory
Are *human* flowers!"

In the sweet-scented pictures, Heavenly artist!
With which thou paintest Nature's wide-spread hall,
What a delightful lesson thou impartest,
Of love to all!

Not useless, are ye, flowers, though made for pleasure,
Blooming o'er field and wave, by day and night;
From every source your sanction bids me treasure
Harmless delight!

Ephemeral sages! what instructors hoary,
For such a world of thought could furnish scope?
Each fading calyx a *memento mori*,
Yet fount of hope!

Posthumous glories! angel-like collection,
Upraised from seed to bulb interred in earth,
Ye are to me a type of resurrection,
And second birth!

Were I, O God! in churchless lands remaining,
Far from all voice of teachers and divines,
My soul would find, in flowers of thy ordaining,
Priests, sermons, shrines!

TURNEP SEED.

A SUPPLY of the following varieties of fresh TURNEP SEED just received, viz:

Yellow Sweedish or Ruta Baga, very fine for stock,
Large Globe Turnep, } Fine
" White Flat do. } for
" Hanover or White Ruta Baga do } table
" Norfolk do. } use.

GARDEN AND FIELD SEED.

A GENERAL assortment of fresh and genuine GARDEN and FIELD SEED, among which are the following:

Red and White Clover,
Blue and Green Grass,
Rye and Orchard do.,
Timothy and Herds do.,
Millet and Lucerne do.,
Seed Corn of every valuable variety,
Seed Wheat,
Buckwheat and Potato Oats,

Kept constantly on hand by the subscriber, all of which are offered for sale at very moderate prices. All orders, by mail or otherwise, executed with neatness and despatch.

SOUTHERN CULTIVATOR.

VOL. II. AUGUSTA, GA., APRIL 17, 1844. No. 8.

COMMUNICATIONS.

For the Southern Cultivator.

CULTURE AND PREPARATION OF INDIGO FOR MARKET.

On this subject, Mr. Editor, I believe no communication to the public has been made through your interesting and useful paper. The Indigo is peculiarly adapted to our soil and climate, and indeed one species of it is indigenous in the Southern States. The pigment prepared from this, is believed to be of a superior quality to that obtained from the foreign plant. For domestic purposes, it has been always used by the farmers of the country, in its wild and uncultivated state. Under the Colonial Government, Indigo was extensively cultivated in South Carolina, and was a source of wealth to the planters on the Santee, and its tributaries. Its cultivation, however, was almost entirely abandoned after the introduction of Cotton; and little is now known of the mode of culture, and its preparation for market. Cotton has, at length, been pushed to the utmost extent of its productiveness; and the foreign demand for it affords to the cultivator but a small remuneration for the labor and capital employed.

The period, therefore, has arrived, when we should examine into our resources, and follow up, with renewed activity and zeal, the multiplied channels, through which our industry and enterprise might successfully extend their pursuits. Let the Planters of the South, in time, and before the evil day arrives when the production of this great staple shall have overreached its consumption and demand, withdraw a portion of their active capital from its cultivation, and direct it to other objects. Happily for us, many objects of encouraging pursuits already present themselves. The manufacture of Sugar from the Cornstalk, may be considered as fully realized. The rearing of stock to an extent adequate to the home demand, has been proved, by judicious experiments, to be entirely within the power of the Southern Farmer. The fabrication of the Cotton into domestic clothing, by the aid of the hand-spinning-machine and the flying shuttle, may be profitably effected, without any considerable diversion of labor from the general business of the farm. Almost all the necessaries of life, and many of its luxuries, are attainable by means, within the reach of every tiller of the soil, through his own resources. All these may be accomplished with few sacrifices, and at a trifling expenditure. Let the system, then, be practically carried out by all, and there will be little danger of our surplus Cotton wanting a foreign market; and less ground for apprehending pecuniary embarrassments and distress, under casual depression of prices.

The Southern Planter, who thus husbands his resources, and wisely employs all the means which the God of Nature has placed within his control, is truly the independent sovereign of all he surveys, and is more above the reach of contingencies than the monarch upon his throne.

Permit me, Mr. Editor, to call the attention of a portion, at least, of the Cotton Planters, to the cultivation of the Indigo; and, through your paper, to communicate such information on the subject, as I have been able to procure from the best authorities. I write not from my own experience. The directions for preparing the pigment, I obtained, many years ago, from an old and respectable Planter in South Carolina. The manuscript which he delivered to me, was from the pen of one who had been extensivly engaged in the cultivation and preparation of Indigo for market, before the Revolution. It has never been published; and may, therefore, impart information on a process little known by the present generation.

The pigment, or dyeing substance of the Indigo, is obtained from the leaves. There are several species of this plant. The *Indigofera tinctoria*, or French Indigo, yields the greatest quantity, and is cultivated in India; but the quality is inferior to the *Indigofera argentea*, or wild Indigo. The former is distinguished by its pinnate leaves, the smaller ribs expanding from the principal rib like the feathers of a quill, similar to the leaves of the pear, and of the lime-tree, and by a more slender, ligneous stem. It rises, in a rich soil, and when well cultivated, to the height of six fee..

The seeds are sown as early in the spring as the climate and season will warrant. In the West Indies, the planting commences in March, in trenches about a foot asunder; and the weed is cut down in May. In South America, six months elapse before it can be cut. In the former, generally four cuttings are obtained of the same plant in the course of a year; but, in the latter, never more than two, and often only one. The cutting takes place when the plant is in blossom, and is done with the sickle. Fresh plantings of the seed are required yearly.

Commence the cutting of the weed in the evening, in time to have the steeper set before it is dark. The plants are laid in strata, and pressed down by weights. When a sufficient quantity of them are laid, pour in water to the height of about four inches above them. One inch and a half above the surface of the water, bore a hole through the side of the vat, and directly over the trough, which is to convey the liquor into the beater. When the fermentation has commenced, the liquor will rise and run over. Let it remain until the stream has ceased, or nearly so. This, in hot weather, will be from ten to fourteen hours after the water has been poured upon the weed, or on the following morning. *Immediately* draw off into the beater, and commence the agitation. Continue this for about twenty minutes, and then let in the lime-water, until you have plenty of grain, but not very coarse. The agitation must be carried on, and frequent use be made of the plate. As soon as a change in the color is perceived, from a muddy green to a purple or blue, the beating should cease. This operation usually requires an hour. There can be no certain rule as to the quantity of lime-water to be used, or the length of time for continuing the agitation. If the Indigo be not sufficiently steeped, it will require more lime-water, and longer beating, and *vice versa*. Having obtained the fine blue tint you wish, stop the agitation, and pour in an additional quantity of lime-water, which will cause the grains to collect and settle in a short time. Be careful, however, not to add so much as to give the liquor a yellow or red tinge: it should be of a clear, but pale green. As the sediment subsides, commence drawing off the water through the upper plugs, and so on to each successively, until the mud alone remains at the bottom of the vat or beater. In the evening, this should be removed into the drainer, and by the morning following, it will be well drained and cracked; which it should be before it is taken out. Having first pressed out the water remaining in it, work up the mud; give it a second pressure, and work it up again until it becomes stiff. After this, submit it to a third pressure, for cutting. Should your Indigo incline to mould, on the drying boards, as it is apt to do in rainy or damp weather, the mould must be wiped off; otherwise it may turn to a grey color. Let it remain upon the drying-boards until you plainly see the quality; afterwards, it may be put up in small barrels. In continued damp weather, during the manipulating and drying process, put the greenish Indigo in the sun, and turn it frequently. As soon as it begins to crack, take it in.

Good Indigo is known by its lightness, or small specific gravity, indicating the absence of earthy impurities; by the mass not readily parting with its coloring matter, when tested by drawing a streak with it over a white surface:

but, above all, by the purity of the color itself. The first quality, estimated by this last test, is called, in commercial language, *fine blue;* the next, *ordinary blue;* then, *fine purple*, &c. The most inferior is known as *ordinary copper.*

The Indigo of Java is superior to that of any other country. The importations into the United States, are chiefly from the British East Indies, Manilla, the Philippine Islands, and from Colombia.—(Comm. Dict.)

McCulloch states, "that the culture of Indigo in the East is very precarious, not only as respects the growth of the plant from year to year, but also as regards the quantity and quality of the drug, which the same amount of plant will afford even in the same season." The favorableness of our climate will secure the cultivators, in this country, from such losses. This is applicable to the culture of Cotton; and the advantages we have in this, will place us beyond the contingencies, in respect to the Indigo, to which the Eastern countries are subject, from the peculiar character of their climate.

CURE OF SWINEY.

Swiney is a disease, by which many of our finest road horses are annually retired from the saddle or harness, and turned out to pasture as almost worthless, or sold for one-third their value. We have seen and tried a number of prescriptions for the relief of this troublesome affection of the shoulder, such as ironing, rubbing with the oil of earth worms, and various stimulating liniments, the introduction of seatons, lengthy incisions with a deposit of poke root, to produce suppuration, &c.; many of which are worthless, and others both cruel and injurious.

The disease may be cured in less than a month, and the horse used daily if necessary, though it is best to give him rest if convenient. As soon as you discover the disease—which will be known by noticing the horse while standing after use, and it may be seen even in the stall, he will sustain the weight of the body on the opposite limb, and put forward the limb of the affected side, permitting it to touch the ground but lightly, limps when hurried down hill, the muscle upon the shoulder becomes thin, and in many instances the skin contracted and tight,—put a twist upon his upper lip, and introduce the small blade of a common pocket knife, (the point of which must be sharp,) into the thinnest part of the shoulder, which will be near the upper margin of the shoulder blade, and push it directly in until you reach the bone, holding the knife as you would a pen when writing, and scratch up the membrane that covers the bone for a space the size of a silver dollar; the knife may then be withdrawn, and after the small quantity of blood that follows is wiped away, the orifice will not be seen. The knife may then be introduced in one or two places below the first, and used in the same way, and the operation is over. This may be repeated in six or eight days: we have but seldom found it necessary to repeat the operation more than twice or thrice, and in many cases a single operation will effect a cure.

Appling, April 10th, 1844.

LECTURE,

On the Elements of Horticulture, delivered before the Agricultural, Horticultural, and Botanical Society of Jefferson College, Miss., at Washington, Wednesday, 1st November, 1843—By THOS. AFFLECK.

LADIES AND GENTLEMEN:—I would just remark, before entering upon my subject, that this being my first attempt at any thing like a public lecture, I would crave your kind indulgence.

The subject I have chosen is, *the nature and structure of plants, applied especially to the theory and practice of Horticulture.* It is a subject embracing a wide field; and one on which it would be difficult to give you much that is really new. But, though many of my hearers are, no doubt, fully as conversant with the subject as I am, and are as intimately acquainted with the works of Decandolle, Knight, Lindley, *Teshemacher*, and others to whom I shall be largely indebted before I close, I shall yet be able to lay open to many of those present, much that is new and interesting in the wondrous laws and operations of vegetable life. And I would especially crave the attention of the ladies, as I shall here endeavor to answer sundry enquiries made of me relative to this subject; and especially in its application to the culture and propagation of flowers and shrubs. I must beg of them, however, to take my *precept* rather than follow my *example*—as I fear that if they judge of me by the condition of my garden, they will not place a very high value on my advice. However, ladies, let me suggest, that though the tree must be judged of by its fruits, it must have time and opportunity to produce that fruit! But, enough of preface.

I have brought with me a few specimens of plants, and parts of plants, that I may enlist the eye as well as the ear, and thus be enabled to make myself more easily understood than I would be otherwise.

Here, then, is a plant which all will recognise, as affording the principal, nay, *only* staple of this region—the cotton plant. Here we have roots, stems and branches, leaf-buds and leaves, flower-buds and flowers, fruit, or seed-vessels and seeds—for the perfection of which last, the seeds, the functions of all the other parts are exercised.

Within this little seed is contained the perfect plant—the embryo, or small particle of pollen—the fertilizing principle, deposited whilst the flower or blossom is in perfection, upon the pistil, by means of which it is conveyed to the cells or seed-vessels, where it is vivified and becomes a perfect seed. Here we have the perfect plant, whether it be the most minute grass of the meadow, or the tallest tree in the forest. This is the means employed by nature for the re-production of plants. But though, under ordinary circumstances, each seed will re-produce its own species, it is by no means certain that it will reproduce the particular variety by which it is borne. Yet, in annual and biennial plants, no other means can be employed to propagate varieties—hence the necessity of removing from those plants, left to produce seed, all others of the same species, or even genus, which would be likely to affect, by the dissemination of their pollen, the variety intended to be perpetuated. Thus, where any variety of cabbage is left to go to seed, no other sort of cabbage, or of kail, or even of turneps, which also belong to the *Brassica* family, should be permitted to show flowers at the same time, in the same garden, unless very extensive. So of cucumbers, melons, pumpkins, squashes, gourds, &c., which all, more or less, affect each other. When care is taken to prevent this—where, by a careful eradication of all varieties likely to affect those left to produce seed—by preserving none but the most genuine forms of a sort for seed-plants—and by compelling a plant, by transplantation, to expend all its accumulated sap in the nourishment of its seed, instead of in the superabundant production of foliage, a crop of seed may be procured, which will produce plants *possessing in a great measure the peculiar properties of the parent variety.*—Thus, by a careful selection, for a series of years, of any vegetable which possesses peculiar form, color or other quality, that peculiar quality becomes as it were fixed, and the plant is capable of producing seed, which will reproduce the counterpart of the parent plant. Witness the different sorts of cabbage or lettuce, which would require but a very slight degree of neglect, in leaving two or more varieties to bloom near each other, to sport, as it is termed, to such extent, that no particular sort would be expected from the seed so produced.

Of this readiness, in cultivated plants, to sport, or produce varieties from the seed sown, gardeners have taken advantage, and have made use of it to produce such changes as they desired. This is principally effected by what is termed *hybridising*, or the impregnation of one variety by the pollen of another. And also by the peculiar treatment of the seed-producing parent—because, as it is found that those plants which have been best nourished, produce seeds which preserve the individual character of the parent most distinctly, it consequently follows that where the object is to *produce varieties*, it will be advisable to lessen the supply of nourishment, by shortening the roots, and replanting in a poorer soil. This and other means, are used by gardeners to produce not only new and improved vegetables, and the endless varieties of beautiful flowers, but also new fruits. The celebrated Belgian Horticulturist, the late Van Mons, by such a system as that I have just touched upon, gave to the world, during his life-time, several hundred varieties of pears, which, for their excellence, as far surpassed the generality of those previously existing, as the bellflower excels the crab-apple.—(*See Note A.*)

But to return to the subject directly before us—the seed of the cotton plant—here we have this seed giving the first evidence of vitality, the embryo plant within has burst its shell, where it lay dormant until it was placed in fitting circumstances to call it into active life. These circumstances are a temperature above the freezing point; a moist medium, such as earth, darkness, and exposure to air. When so placed, the seed undergoes certain changes—one extremity of the young plant, as we see here, ascending for the purpose of finding light, and forming leaves and branches, through which to carry on those chemical changes, necessary to its growth and existence; and the other extremity descending for the purpose of finding a constant supply of crude nutriment, and becoming perfect roots.

The *root* is the part that strikes into the earth when the seed begins to grow, continuing to lengthen, for the double purpose of fixing the plant in the soil or to some firm support, and of absorbing food in a fluid or gaseous state. Roots are distinguished from the stem by the absence of leaves and leaf-buds, of evaporating pores, and of pith in most plants. Hence such underground bodies as the tuber of the potatoe, the bulb of the onion, hyacinth, &c., are not roots. Roots do not absorb food by their surface; it is chiefly by their young and newly formed extremities, called *spangioles.* Hence the preservation of the spongioles uninjured is essential to the successful removal of a plant from one place to another, and care should be taken to preserve the smallest fibres of the roots uninjured, instead of *trimming them off*, as is usually practised.

Whilst touching on the subject of transplantation, I may remark that it is an operation requiring much more care than is usually bestowed on it. The most trifling plant, worthy of removal, is worthy of being handled with care. If a plant be removed by digging it up so as to leave nothing but a *club* where the *mass of roots* should be, and tramping it into a hole barely large enough to receive it, leaving it unstaked to be shaken about by every wind that blows, what reasonable hope can be entertained that it will do more than send forth a few sickly looking leaves, to wither and die during the summer? Whether the plant be large or small, an evergreen or not, remove it with a large ball of earth. If it be a good sized tree, there is the

greater occasion for care in its removal. Stake it effectually, so that it cannot be shaken about; if it is loose, the roots cannot exercise their functions.

The preservation of the spongioles, or rootlets, is indispensable to the vigorous growth of the plant. Hence, *deep plowing*, after cotton and corn have attained growth sufficient to send their roots out into the furrow in search of nourishment, is decidedly injurious. Hence, also, if, when a plant shows too strong an inclination to run up into stalk and leaf, a coulter be run close to the plant, the supply of nourishment is checked, and fruit-buds instead of leaf-buds formed.

The spongiole is the most delicate part of a plant, and the most easily injured; and, as it has no power of selecting its own food, but will absorb whatever may be brought in contact with it, in a sufficiently fluid state to be taken up by it, they not unfrequently, being developed in a soil of an unsuitable nature, absorb matter that proves injurious or fatal to the life of the plant. This may explain why trees suddenly become unhealthy, without any external apparent cause. The removal of the surrounding soil, and replacing it with some good compost, will most commonly effect a cure.

Plants have the power of replacing spongioles, by the formation of new ones; so that, though plants are seriously injured by their loss, they may yet recover from the injury. But this power depends upon the co-operation of the atmosphere and other circumstances. If the air is damp enough to hinder evaporation from the leaves, spongioles will have time to form anew; but if the atmosphere is dry, the loss by evaporation will be so much greater than can be supplied by the injured roots, that the whole plant will dry up before the new spongioles can form, and death will ensue.

Here we have a key to the operations of transplantation and propagation by cuttings, scions and buds. Although, as I have before remarked, roots are destitute of leaf-buds, and leaf-buds being essential to the multiplication of an individual, it would follow that roots can never be employed for the purpose of multiplication—yet, some roots have the power of generating leaf-buds under certain circumstances, as the quince, &c. The cause of this power, existing in some species and not in others, is unknown, and is a power not to be depended upon. Cuttings set out previous to the appearance of the leaves in the spring, will take root and grow; but this, like the exception just spoken of, cannot be relied on, and is only discovered by accident. The grape, and many other vines, some roses, jesamines, &c., have this power, and may be propagated in that way. If attempted, let it be in a sandy or porous soil, in which bury the cuttings, which should be of some length, so as to leave but a single bud above ground. It a little grafting-wax be put on both ends, it will render the experiment more certain. The immediate cause of the formation of roots is at present involved in obscurity; but the fact is well known that some plants, when being propagated by cuttings, produce roots with much more facility, and in a shorter time, than others. During the summer, after the young shoots of that season have made a growth of two or three inches, is the most favorable time to form plants from cuttings. The proper medium to use, is two parts of sharp sand from the creek, and one part of good earth, or *leaf-mould*. After laying a foundation of a few inches of gravel, or broken bricks, inside of a box or frame, form a bed of the mixture of sand and earth, say to the depth of eight inches, nail a few uprights round the frame or box, in such a way as to support a mat or piece of old carpet, to keep off the sun and air. It is better, when it can be done, to lay a glazed sash, as in forming a hot-bed, over the bed; which again can be shaded by matting. Where the experiment is on a small scale, or the cuttings rare, a flower-pot and tumbler or bell of glass will answer every purpose. The cuttings, as I before remarked, are formed of the young shoots of two or three inches in length—the shorter the better—cutting off with them, with a square cut, half an inch or so of old wood; trim off all the leaves but one or two, and insert the cutting in the bed, leaving only a bud or two exposed, and within an inch or two of each other. They must now be kept shaded, and in a close, warm, moist atmosphere—darkness, moisture, (from frequent watering, the sand not permitting too much water to remain, as it drains off,) and perfect rest being necessary, as well as a downward circulation of the sap, which is effected by the action of the leaves on the upper part of the stem—the roots not being able to exist of themselves, without the leaves to create the action of drawing up the juices the roots absorb—therefore, as a general rule, a cutting without leaves will soon perish. In three or four weeks, the cuttings will give evidence of growing, and may be carefully taken up, and planted out in nursery rows, and shaded and watered as long as necessary.

There are other methods of propagating, as by layers, single buds, and so on, but it will be unnecessary for me to say more on this subject—the preceeding hints will, I think, suffice.

To return to the roots and their functions. After the juices have circulated through a plant, and performed their destined offices, what remains unfit for its further nourishment returns to the spongioles, and is by them thrown off; this substance, so thrown off, is unsuitable, and even poisonous to that species of plants, yet is not so to other species; it may even be suitable to them. Thus, soil may be rendered impure, or, as we inaccurately say, *worn out*, for one species, which will not be impure for others. Here we have the true theory of the rotation of crops, which, in practice, is found to have created an entire new era in farming, and which we would do well to apply to our cotton crop. It also accounts for the fact, that young apple trees, for instance, cannot thrive when planted on the site of an old orchard; where, on the other hand, young peach trees would succeed well. It likewise accounts for the natural rotation of trees, which has been found to exist in the ancient forests of this part of the globe—and for the necessity of repotting plants grown in greenhouses every one or two years, and for many other circumstances hitherto unexplained. The root is never entirely dormant except when frozen; during the winter it is slowly collecting juices for the supply of the spring; where the period of rest, or winter, is long the store of juices is large, and vegetation in the spring is rapid and luxuriant. This accounts for the quick growth in northern climates, where plants commence their growth and mature their fruit within the short space of three months.

The stem is that part of a plant which is developed above ground, and which we here see taking an upward direction, on the germination of the seed, going forth to bear leaves and leaf-buds, flowers and fruit. The more erect a stem grows, the more vigorous it is. The stem is covered by bark, having pores on its surface, to stop up which would be as injurious to the health of the plant, as the closing of the pores of our skin would be to us. Hence, all thick, paint-like applications to the bark of trees are injurious if allowed to remain for any length of time. Whitewashing is considered particularly injurious, as well as in wretched bad taste. It is of great advantage, however, to give the stems of all fruit and shade trees a good scrubbing once or twice a year, with soft soap and water, at the same time scraping off all the rough bark or moss, that might afford harbor for insects, and close up or impede the pores of the bark. The stem is increased in diameter in some plants by the addition of new matter to the outside of the wood & inside of the bark; these are designated as *exogengus*, for example the oak. Others increase by the addition of new matter to their inside, as the cane, and are called *eudogenous*. All know the difference between *heart-wood* and *sap-wood*—how much more durable the one is than the other. The *heart-wood* was, when young, *sap-wood*, (or *alburnum*.) It has undergone a change which has rendered it solid, and much less subject to decay—secretions conveyed to them from the roots, have been prepared by the leaves, and returned downwards through the bark, and from the bark communicated to the central part of the stem. To give you a full account of the nature and properties of the different parts of the stem and bark, with the various discoveries in the circulation of sap, and the theories advanced to explain much that yet requires explanation, would compel me to encroach too much on your time, and moreover, is not altogether necessary to my purpose. Stems have the power of propagating an individual only by means of their leaf-buds—which are rudiments of branches, enclosed within scales, or imperfectly formed leaves. Leaf-buds are at first nourished by the fluid lying in the pith, but they finally establish for themselves a communication with the soil by means of the woody matter which they send downwards. Their developement or growth will, of course, be in proportion to their nourishment; and consequently when it is wished to procure a young shoot of unusual vigor, all others near to it are rubbed off, so as to accumulate, for that one shoot, all the food that would otherwise have been consumed by several. *Cutting back to a few eyes*, as it is termed by gardeners, is an operation in pruning, to produce the same effect, directing the sap as it ascends, into the two or three buds that are left on the shoot, instead of allowing it to be divided amongst the whole. Many of our finest flowering shrubs, the rose, crape myrtle, jessamine, and many others, are much benefitted by a pruning of this kind—but before practising it, it is well to have an eye to the peculiar growth of the plant. Many roses, indeed the greatest number of them, produce their buds at the termination of the young shoots—others again upon the short spurs from the old wood, and both should be pruned accordingly. The althea, crape myrtle, and others, bear their flowers upon the young shoots of that season's growth, which should therefore be nipped out, where they are too numerous, before they have made more than a few inches' growth. Those that are left, may be cut back to a few eyes, in the fall, by which, for the reason I have just given, they will throw out stronger shoots the following spring. Plants are very readily propagated from leaf-buds; in fact, they closely resemble seeds—differing, however, in the leaf-bud propagating the particular individual from which it is taken, whilst the seed propagates only the species. If a cutting with a leaf-bud on it, be placed in circumstances fitted to the developement of the latter, it will grow and become a new plant; certain of these circumstances I explained when treating of propagating by cuttings—of others I will treat presently. If this happens when the cutting is inserted in the earth, the new plant is said by gardeners *to be upon its own bottom*. But if it happens under other circumstances—when the cutting is applied to the dissevered end of another individual, called *a stock*, the woody matter which, when inserted in the ground, became roots, is here insinuated into the tissue or fibre of the stock, to which it thus attaches itself, and is said to be *grafted*; the cutting being called *a scion*. There is, therefore, little difference between cuttings and scions, except that the former root into the earth, and the latter into the plant. A piece of the stem—or cutting without a leaf-bud so treated will die; but a leaf bud separated from the stem will become a new individual, if its vital energy is sufficiently powerful. And this, whether it is planted in earth, into which it roots, like a cutting—or in a new individual, *a stock*, to which it adheres and grows like a scion. In the former case it is called *an eye*, in the latter *a bud*. This shows to you the principles of budding and of grafting. I came prepared to explain both of these processes to the eye as well as to the ear, but fear that I should

trespass too much upon your time and patience. Shall I pass it over, or shall I not?

[Here Mr. Affleck introduced specimens of various plants, upon which he illustrated the experiments to which he alluded in his address. We also had sent us the Western Farmer and Gardeners' Almanac, for 1842, with the request to make an extract from it, on budding, grafting, &c., but as we have not the necessary plates, we are obliged to leave them out.—Eds.]

To return to the subject of the leaf-bud. Where there are no leaf-buds, there is no addition made to the wood of the plant; its stem and branches will not increase in diameter—hence it is most injurious to trim up the stem of a young tree, a fruit tree, say—for, as the destruction of the leaf-buds is accompanied by the absence of wood, the tree cannot thrive as it would otherwise. There are, in addition to the regular leaf-buds, that are called *adventitious*, or those produced by particular circumstances. They may be generated by sap in a state of great accumulation and activity, produced by abundance of nourishment—by a healthy, vigorous plant being cut down, and so on. When this excessive vigor is produced in a plant, it is favorable to the production of leaf, in preference to blossom-buds. This would lead me to the subject of pruning again, and particularly grape vines, but I must pass it over for the present. The leaf-bud and the flower-bud are supposed to be the same in the earliest stage of their organization; but soon after, the change takes place. Excessive vigor is favorable to the production of leaf-buds, and consequently of wood. On the contrary, when rapid and vigorous vegetation is checked, blossom-buds and consequently fruit will be in abundance; thus, fruit is seldom borne on the thick vigorous shoots of the peach and other fruits, but generally on the slender and less vigorous ones. If an unproductive tree is transplanted, it often becomes productive from the check given.—(*See Note B.*)

Leaves are, as it were, the *lungs* of the plant. They elaborate the sap which has been collected by the spongioles of the roots, and conveyed to them, the leaves, by the alburnum or sap-wood, converting it into the secretions peculiar to the species; their structure enabling them to expose the sap, for this purpose, to the action of the atmosphere. Scattered over the surface of the leaf are numerous apertures or cells, called *stomata*, which have the power of opening or closing as the circumstances may require. And as it is by their means that the preparation of the necessary secretions go on, and being of such vital importance to the plant, it is absolutely necessary to the health of the plant, that they be not choked up with dust or dirt, or injured by insects, or otherwise destroyed or removed. The cleaner the leaves of a plant are kept, and the more they are exposed to a moderate degree of light and air, the more the plant will flourish. We thus find the leaf to be a beautiful contrivance for exposing a large surface of crude sap to the influence of the external air and solar light, by the operation of which it is rendered capable of being converted into the different substances required for the growth of the plant, and the production of its fruit and seed.

The flower is that part of the plant destined to form and perfect the seed. It has two principal parts, the calyx or outward envelope, and the petals forming the corolla. In this specimen the petals are colored, and give beauty to the flower; but in some plants the reverse is the case—the calyx is colored, as in the Fuschias. Here are the stamens—here the pistil. The *stamens* bear on their summits an organ, called the *anther*, which contains a powder called *pollen*. When the anther is full grown, it opens and ejects the pollen, either dispersing it in the air from the elasticity with which it opens, and by which it reaches the summit of the pistil; or at once depositing it there, or exposing it to the action of the wind, or to insects, carry it to its proper destination. The pollen consists of exceedingly minute hollow balls, or cases, containing myriads of particles called *granules*, which are the fertilizing principle of the stamens. These are light, and being only liberated from the anther during very dry weather, are scattered by the wind and insects to a great distance. Hence the necessity, of which I before spoke, for keeping plants, that are left to produce seeds, as far apart as possible from each other, where of the same species. In double flowers, the stamens are transformed into petals; or the petals and the sepals, or leaves forming the calyx, are multiplied—hence, few double flowers produce many or perfect seeds. The pistils have at their base small cells or cavities—in the ripe state called seed sepals—in which bodies called *ovula* are placed. These ovula are the rudiments of seeds, and are vivified by the pollen conveyed to them through the pistil. In wild plants, the stigma or secreting surface of the pistil, is usually acted upon only by the pollen of the stamens which belong to it. In this case, the seeds thus vivified, will, when sown, produce new individuals differing very little from that by which they themselves were produced. Therefore, wild plants multiply from generation to generation without change. But gardeners use artificial means to cause deviations from this law; they take the pollen of one species, and with it impregnate another species, by which they seek to produce seeds that will originate an individual possessing properties common to both parents. (*See Note A.*) These are called hybrids, and were at one time, reasoning from analogy, supposed to be sterile; but experience proves that hybrids will produce perfect seeds. These seeds, however, are of course not to be relied upon to perpetuate the particular variety that produced them; this must be done by cuttings, buds and grafts. The fruit, in the plant before us, is represented by the cotton boll. The outer rind here takes the place of the edible flesh of the apple, the pulp of the peach and so on—being a provision of nature for the protection of the seed. The fruit, strictly speaking, is the pistil arrived at maturity. When the calyx adheres to the pistil, and forms a part of the fruit, as is the case with the apple, pomegranate, &c., that fruit is called *inferior*. But when the pistil alone ripens, the calyx not adhering to it, as is the case here, and in the peach, the fruit is called *superior*. A *superior* fruit consisting of only one, or of a very small number of transformed leaves, it has not, like the branches, the power of communicating with the earth, and of feeding itself, and elaborating or preparing its own food, but must depend upon the leaves on the young shoots above it—as we see here, and in the peach: but *inferior* fruit, having the calyx leaves at its termination, has a more powerful communication with the branch, is enabled to attract its own secretions or food more readily, and does not require the assistance of leaves above it. These facts require to be borne in mind in pruning: but, as the remarks I before made on this subject will apply here, I will not repeat them.

And now, having followed the plant through its entire course of existence, from its first appearance from the seed, until the seed is again produced, I will come to a close—assuring you that I feel grateful for the attention you have given me, and the patience with which all have heard me through a lecture that must have been somewhat dry to many. It has assisted me in what would otherwise have been quite a task—*my first public lecture.*

Notes.—(A.)—Dr. Lovelace, of Wilkinson county, submitted to the appropriate committee, at the fair, a specimen of *cotton*, which I presume to be a *hybrid*, that certainly, in its extreme fineness and length of staple, and in its productiveness, promises to reward Dr. L. for his enterprise. The variety seems to be already tolerably well established, but I have no doubt yet sports much; and will require some years of careful cultivation apart from any other variety, and selection of seed, to ensure *a distinct variety.* Dr. L. deserves the thanks of the society, which have been awarded him. He has mine, sincerely, for the few seeds in my possession, which I shall endeavor to increase.

(B.)—Although this has long been proven an established fact—that the curtailment of the roots, or by some other means giving the plant a check in its growth, will cause the production of fruit-buds and fruit, it has but recently been included by gardeners as a part of their regular practice. The Pear is well known to be long in producing its fruit, particularly seedlings, or grafts upon *free* stocks, or tall-growing stocks. By laying bare the roots of a tree, which continues year after year, to grow vigorously, but produces no fruit, and pruning away the largest lateral roots, it will be thrown into bearing almost immediately—at all events, after the lapse of a season.

From the Central New York Farmer.

THE EFFECTS OF AGRICULTURAL PAPERS ILLUSTRATED,

OR THE STORY OF UNCLE TIM AND HIS SON.

Mr. Timothy Treadmill, was about the tightest man that ever came from "down east," but although penurious in the last degree, he never became very rich. He was a firm believer in the doctrine of "following in the footsteps of his predecessors," and practiced it to an iota. The way his father planted corn, he planted it; the same time in the moon that his father sowed peas, he sowed them. The last pair of cart wheels that were seen wearing a streak tire, were Uncle Tim's—and the last of the old wooden plows was seen mouldering into its original elements at the back side of his wood-house. In short, with the exception of adopting some few improvements in the way of implements, he was precisely as good a farmer the day he left his father's roof, as he was forty years afterwards.

That there was any better way of farming than that practiced by his father and all the rest of the good people down in old Connecticut, for so long a time, nothing short of actual demonstration could make him believe. The idea of *improvement* in farming, seemed to be as absurd in his mind, as that the bees should set about making an improvement in the construction of their cells, or the birds in building their nests. Book farming and *new notions* were his utter abomination. What! such men as Judge Buel, who never pretended to be a farmer till he was forty years old, undertake to teach *him* how to raise corn and potatoes, who had been a farmer all his days, and his father before him. *He* take a *newspaper* to learn how to farm! No—he knew better than to pay his money for such foolery as that. If any body wanted to read the big stories of *them new fangled farmers* about Albany, about their great crops and their new fashioned kinds of cattle and hogs, he was willing they should: but, for his part, he believed he could farm about as well as those that printed newspapers, and raised spotted hogs to sell.

His farm was "suitably divided into mowing, pasturing, tillage and wood-land." What was in pasture when he bought the farm, remained in pasture still, and what was "mowing" at that time, the plowshare had never disturbed, and what was plowland then, remained still the same. His manure always laid at the barn till fall, because it was so much better for corn after it was nicely rotted; and his barn-yard was so situated that the water would run from it in all directions—of course it was always *nice and dry.* When he happened to have a little manure left after planting, he has been known to put a little sprinkling on some spot in his meadow, where he thought the daisies and June grass were likely to run out; but as long as the daisies flourished well, he was not alarmed, for he said the farmers down in Conn., thought they made about the best hay of any thing. In hoeing, he was not over-anxious about the weeds, for he said they kept the ground light and moist, and that where the quack grass was thickest, he always had the best corn. But as Uncle Tim was not deeply

read in natural philosophy, it did not occur to him that the corn and quack grass both would grow most luxuriantly on the richest spot of ground.

But, as I said before, Uncle Tim never grew very rich; for, although he saved every thing, the fact was he had *not much to save*. His cattle and his fields being lightly fed, fed him lightly in return. It seemed to him that all he gave his cattle, beyond what was barely sufficient to keep skin and bone together, was about the same as thrown away, and every hundred of hay he could save to sell in spring, was so much clear gain. And, as for laying out any expense to increase his quantity of manure, it was a thing he never dreamed of. But, as I said before, starving his cattle and his crops proved to be a bad business, for there seemed to be a fair prospect that it would end in starving himself. He could perceive that the products of his farm gradually diminished from year to year, still he never seemed to suspect that the cause was to be attributed to his bad management.

There were, however, good things about Uncle Tim. And, although errors and prejudices of this kind seem to be, in a great measure, inexcusable, his were entitled to as large a share of charity as those of most other men. There was one thing about which he evinced quite a commendable degree of liberality. He had a son growing up to manhood, and his better feelings induced him to go so far as to say, he thought young people now-a-days ought to have a better education than they had forty or fifty years ago, when he was a young man. In fact, he afforded his son a very tolerable opportunity for acquiring a good common education. And finally, young Timothy was becoming quite a reading, and consequently, intelligent young man. This, however, led to consequences entirely unforeseen by the father, and which, for a while, gave him a good deal of uneasiness.

In his intercourse with the more intelligent of their neighbors, the young man had occasionally met with agricultural papers, and perused them as far as opportunity permitted, with a good deal of interest. He perceived that many of his father's notions about farming were erroneous. The evidences that great and important improvements were taking place, were, to his mind, altogether irresistible. And, although he well knew that his father would oppose any innovations, he began occasionally to make known the result of his reading and reflections on the subject, by proposing some little changes in their mode of management, and finally intimated that he should like very well to take the Cultivator. But it was a desperate case; for, whatever faith Uncle Tim might have had in more distant things, it was clear that in the matter of *agricultural improvement*, he had neither faith nor works. The old gentleman, while he felt disposed to gratify his son in all prudent desires, could not but feel vexed to find him inclined to depart so far from what he considered "the good old paths." Things went on, however, much after this fashion, for considerable time. Timothy would occasionally quote Judge Buel, and speak of the increased profits of the improved methods of husbandry. But, to all these representations, the old gentleman had always a ready answer. All this, he said, might do very well for *rich men*, who lived near a market, where all the productions of the farm would sell for ready money, and plenty of manure could be had near by and for little or nothing. But, for small farms, situated as they were away back in the country, to attempt to take these big men for a guide, would be ruinous extravagance. One of Timothy's suggestions, however, rather staggered him.

"Well, father," said he, one day as they went out toward the barn just after a shower, and the streams of water, as *black as your hat*, were running out of the yard—"I think there is one thing we small farmers in the country might do as well as the large ones that live near the cities. If we can't buy manure, we might take care of what we have. You see that if our barn-yard was *turned bottom up*, it would be just in the shape recommended by Judge Buel, and would hold all this liquid manure that we see running off into the road."

Somewhere about these days, it came into the heart of Uncle Tim, to visit his old friends and relations down in the land of wooden nutmegs; and, as his son had never seen much of the world, he thought it might be well enough for him to go along too: so, after mature deliberation, it was decided that it would be most economical, on the whole, to go with their own conveyance. Old gray, to be sure, had been worked hard and not *very high fed*, and was a little thinish, but Uncle Tim guessed he'd do to go well enough—he would have a good rest and good keeping down there, and plenty of time to recruit after he come back. Well, after preparing their box of provisions and their bag of oats, they set off.

But Uncle Tim had never foundered a horse in all his life, by giving him too many oats, and he didn't mean to begin then; so the bag was not a very big one, and the journey was somewhat longer than they calculated—old gray was a pretty slow horse the latter part of the journey, and if he could have told his mind, would probably have said he was very glad when he reached the end of it. He had then a week or two to rest, but it seemed as if hard times had got to Connecticut before they did, for the granaries were very poorly supplied with oats. The time, however, soon arrived when they were to set their faces homeward; and the poor old horse, although somewhat rested, was not very much improved in his capacity to perform a journey. Even their small bag was but scantily filled, and to buy oats on the road, seemed to Uncle Tim a very improvident way of travelling. So they jogged on with such speed as the circumstances permitted; but before they were within fifty miles of home, old gray gave out, and they were obliged to haul up. The fact was, old gray was a good horse, but he was *used up*. Although he had been a good horse a great while, it was not old age that prostrated him. He had skin and bone and muscle, and wind, and four sound legs. The machine was in order, but the *moving power* had been withheld. The poor old horse was as useless as the steam engine without the steam.

Well, Uncle Tim and his son were in a bad fix. Their passage home in the stage would cost considerable money, and then to leave old gray there to recruit, and the expense of sending for him, would increase the sum to a pretty important amount—and they could hardly think of selling the old horse for the small sum of ten dollars, which was the most they could get offered for him. The result of their deliberations was, that old gray was left with a farmer near by at a moderate expense, and the father and son took passage home in the stage. It so happened they were the only passengers, so they had plenty of time to think, and occasionally, as the spirit moved, to talk a little.

"Well, father," said the young man, after a pretty considerable long silence, "I don't know as you think as I do, but it appears to me that our farm and old gray are very nearly in the same situation."

"I don't know," said his father, "what there can be about a farm and a horse, that can make them resemble each other so very much."

Timothy then undertook to explain.—"There is, said he, what was *once* a good farm, and the foundation on which to make a good farm now. So there is what was *once* a good horse, and a good frame to make a horse of now. But both have been so overworked and poorly fed, that they have become exhausted and are of but little value. The farm, you know, produces little, if anything, more than enough to pay for the labor we bestow upon it, and the value of old gray we have had a pretty good opportunity of testing. Now, it appears to me that I can convince you that under a different course of management, both the farm and the horse would have much more than repaid the extra expense estowed upon them, and been worth at this day more than double what they are. I am very certain I can as respects the horse, and it is equally clear to my mind with respect to the farm. Suppose, then, we had given the horse one peck of oats per day, for the last two months in addition to what he has had—would not that have enabled him to work considerably harder than he has done, and kept him in good condition? The old gentleman could not but admit that he thought it would. Well now, said Timothy, do you not think that if old gray was in good working order, he would sell for forty dollars? Yes, and more too, was his father's prompt reply. Now, said the young man, let us calculate the cost of the oats: one peck a day for two months, would be nearly sixteen bushels—that, at twenty-five cents per bushel, would amount to four dollars: and, as things have turned out, I am sure you will be willing to admit that sixteen bushels of oats, disposed of in that way, would have been a very judicious expenditure, as, according to our calculation, it would have produced a difference of thirty dollars in the value of the horse."

"But, said his father, "old gray is actually worth more than ten dollars, as it will not cost thirty dollars to recruit him up."

"Perhaps not," said Timothy, "but whatever it does cost, added to the expense of our getting home, and the loss of the work of the old horse after that, would, at any rate, have been saved by the four dollars worth of oats. And now," said he, "with regard to the farm, you have always told me that it was originally rich and produced great crops, and if it were as good now as it was then, could we not make one hundred dollars more easily than we can fifty now?"

"Yes," said his father, "I suppose we could."

"Well, now," resumed the young man, "the only question is, whether or not it could have been kept up in its original state of fertility till this day, with the ordinary available means, by a different course of management. I think that it could—and will try and explain, as well as I can, with my small knowledge of improved husbandry, what course of management would have been required to effect so desirable a result. The first great object would have been to increase, by all prudent means, the quantity of manure, and either to use it in a fresh state, or prevent waste by washing or evaporation; and one means of accomplishing this, would have been, to *sell no hay*, unless a corresponding amount of manure could have been purchased, but to keep more stock, or perhaps, to feed what was kept better, so as to consume all the fodder at home. The next change would have been to divide the farm into smaller lots, so as to pursue what is called a rotation of crops; that is, that the whole may be in turn manured and appropriated to the different kinds of crops: other changes would have been to cultivate the land better, to procure more and better implements, and to pay more attention to the breeding of animals of all kinds.

"These are the important changes required by what is called "improved husbandry." There are, of course, many small matters belonging to each that I have not mentioned.

"And now, although the farm is, as we say, *run out*, a resort to the same measures will raise it to the desired state of fertility; but the improvement must, of course, be very gradual unless considerable expense is laid out at the commencement, for manure, fencing, &c. I am aware that this may not appear so plain a case as that of the horse, but I am not able to see how any one can, upon reflection, avoid coming to the conclusion that the two cases are precisely similar. The *fact* is, they have both been starved, and for all useful purposes, in their present state, are of very little value. By good feed and proper management, both may be restored."

Uncle Tim kept cool all this time, but it was

evident, from the way he used up the cuds of tobacco, that he felt a leetle uncomfortable.

"Well," said he, "I don't think that I shall ever become much of a *book-farmer* myself; but, as I am getting old, and as I expect the farm to be eventually yours, and as you are so confident that these new ways are the best, I am willing that you should take the management and try, and satisfy yourself and *me too*. I will try and look at your management without prejudice, and at the end of three years, should we both live till that time, if I feel satisfied that the new way is the better way, you shall have a deed at that time."

We will only add, that sometime before the three years expired, Uncle Tim's deed was made out, "signed and sealed;" and what was still a greater wonder, he had become a constant reader of the Cultivator, and said he really did think that Judge Buel had done some good in the world.

Finally, we cannot but hope that many Uncle Tim's are every year becoming converted from the error of their ways.

From the Albany Cultivator.

SUGGESTIONS TO COTTON PLANTERS.

Willis Gaylord—Sir—I quote here your queries propounded to me in your very friendly letter, also the remarks following those questions, and will endeavor to give you what I think are the facts in the case, leaving you to use either, to satisfy yourself or others, as you may wish. You say, "it is an error in me to suppose that the cotton growing districts of the United States, mistake their true interests, by devoting their attention to that article so exclusively. Would not a more mixed husbandry, one that should secure to the planter, from his own soil, his required supplies of beef, mutton, bacon and bread, be preferable to risking all on one crop? I take it for granted, there is no good reason in the nature of things why this might not be; I suppose experience has demonstrated that there is no difficulty whatever in the growing of cattle, sheep, (and fine wooled ones too,) and pigs, in quantities sufficient for the wants of the planter; and that the system of extensive purchases of articles of food now so common, is more the result of habit than of necessity."

It gives me no inconsiderable pleasure to give you an answer to all this matter, by showing you what is now done by a great many farmers, and some planters, in this part of the cotton region, which may tend to stimulate others to equal exertions, and will show many, who live north of us, that we are not dependent for supplies to our northern friends, and thereby induce them to feel more like we were brethren and equals, than that we were dependents. The capabilities of our soil to produce, our climate to perfect, and the energy of the sons of a southern clime to effect reasonable objects when necessary, are misunderstood by many, in even this country, for that author of the effect of climate, is a southerner, and it is reasonable to suppose that there are far more in a northern country.

All experience has proved in every country, where yet tried, that mixed husbandry is preferable to a devotion to any one crop, and to a certain extent is true in the cotton region; we must have no other crop to interfere in the gathering, that requiring all the time and attention of the farmer. That there is too much reliance on the cotton plant, the practice of our farmers will be a sufficient proof, and that much other business might be introduced that would not conflict with the interest of the cotton grower, we all now believe.

We can assuredly make an abundance of beef, mutton, bacon, bread and wool, to feed and clothe us well; we can also rear our own horses and mules; and I make no question but what we could add sugar and molasses, with silks for our fair dames, would they but take hold in a proper spirit. I make not these assertions without absolute proof, and enough to satisfy any jury of 12 men in the United States.—My five nearest neighbors in this county, having near on to 300 persons in the aggregate, have made for the last 3 or 4 years more meat, corn and beef, than was necessary; I might add mutton also, although the quantity consumed is small. I can better say of myself than of others; I must therefore rely more on this, trusting a bare exposition of facts will be construed fairly.

I can make an average crop for any consecutive 10 years, (and am even willing that the last 4 be counted in, as I have been here myself only 4 years since 1836,) 6 bales of cotton weighing 400 lbs., 200 bushels of corn, 500 lbs. of pork, raise 5 lambs, 3 calves, per hand that works in the field, with 1 colt to 4 hands, and an abundance of oats, rye, millet and fodder, potatoes and garden vegetables, to feed one horse to each hand, all cattle in the winter daily, and whites and blacks. I have been much engaged in putting the farm in ship shape order, and have lost much time from the mere farm work, but I can make a better showing than this, and make no question that I will ere 10 years pass, make, besides my crop of cotton, (6 bales,) pork and hay for sale. I can even now sell off yearly some half dozen beeves, a few milch cows, 30 or 40 mutton, and have sold on an average, $500 worth for 3 years, without at all interfering with what I say can be made, or at all injuring in number or quality the stock that I found here on my return in 1839. I am not yet fixed, for you well know how long it requires to get a farm properly arranged: owing to this, and to a never ending range for hogs, I am harrassed yearly for meat. The pigs I had castrated and spayed in 1840, Jan. and April, for killing Dec. 1842, numbered 93, and although I had an abundance of corn, I did not kill *of them* over 20 head; the others I have never seen. I must raise my meat in an enclosure.

Now, sir, if one man can do this, others can, and if cotton will not rise over 8 cts., we will all do it, and do more, for we can and will make our own clothing.

The great difficulty in this country has been, cotton has been to all appearances, a remunerating crop, and in many instances only in appearance; for when it rises, and the planter sells a per hand crop of $300, every thing is high in proportion, and by purchasing every thing, he is really but little better off at the end of the year than at the beginning. My own opinion is, and I have made every reasonable effort to give it publicity, that it is a duty every man owes his family, his country, to make every thing necessary which will not withdraw his force from their trade, and after which, as much cotton as he can—thus making sure of bread, meat and work animals, so if he makes only 4 or 5 bales per hand, those few bales will be nearly clear.

I have a portion of a mutton now in my smoke house that is very passable meat, though not fat; killed off a rye patch, which was sown on the corn ground, no plow being used at all. This season being more unfavorable for sheep than any I have ever seen, continued rains, not a head of sheep has been housed an hour; and worse on my sheep than on natives, being part bred Bakewell. I killed some two of my choice veals this fall, no extra care or keep, and a beef near 4 years old, a spayed heifer raised entirely in the woods, with a run in the field after gathering corn; she weighed 426 lbs., and gave me 46 lbs. of tallow; she was, to appearance, no fatter than when turned in, and was only turned in to give flavor to her meat. I have got over 30 lbs. of tallow from a beef 6 to 7 years old, killed out of the woods. I therefore say there is no difficulty in raising either beef or mutton. Pork can be bought, raised in this county, at 3 cents—enough to prove that we can raise pork. My own opinion is, that we can raise pork cheaper than those countries where pork is the staple commodity. And here are my reasons: a farmer can cultivate 10 acres of corn land per hand, besides enough in cotton to ensure him 4 bales, and a large crop of oats and sweet potatoes; which, with the aid of a peach orchard, planting his corn land with peas and pumpkins, he can rear readily double the quantity of hogs he will require; he then can take time to handle these 4 bales so as to nett him, in price, over 5 bales, and give him the surplus quantity of pork a clear gain. Thus, in reality, making, by his staple production, a fair crop; which, as a matter of course, gives him the pork free of cost. Should he require a crop of 6 bales, let him plant for 5 and handle well, to make in price and saving of expense, the 6th bale.

A neighbor of mine has killed hogs averaging 300 lbs., this winter: they were raised entirely in the woods, as our stock hogs are raised, then turned into the pea field, and afterwards corn fed for a few weeks; clearly proving the good effect of crosses on his stock. Four years ago, his stock did not average 200 lbs., and raised as now, but the range far better: he has killed 46 that will over-go 275 lbs., some going to 320 lbs., 18 months to 2 years old. He has purchased of me boars at eifferent times. The exact weights I will ascertain, and publish in the S. W. Farmer.

We do not raise large cattle or hogs, or make large yields of corn, like our northern brethren; but have a fair range, and with land not worth over $5 to $15 per acre, we can afford to cultivate more.

I have a friend who, in South Carolina even, makes what is considered a fair crop there; and though he works something over 100 hands, yet makes corn to sell with his own meat. In an address delivered in South Carolina, by the Hon. Geo. McDuffie, he states he makes a fair crop, raises his own corn and meat, and even his work horses. I think this statement is made in his address; and I think it entirely feasible, for every county in a cotton growing State, to do the same, and supply its county seat with bread and meat.

Were I to devote myself entirely to a cotton farm, not attend to improving stock and buildings, I feel perfectly certain that I could sell as much meat as I would use, raise enough horses to fully supply the wear and tear, and yet sell my 6 bales of cotton. There are many even here who would doubt it; but, sir, I am a practical farmer, make farming my only business, and I feel that injustice is done, when called theoretical, because I have had the chance of receiving a first rate education, and read more or less every day of my life. I only ask for the same measure to be meted unto me, as is done to other men who reside on their farms, and superintend themselves all the minutiæ of farming. Yours, &c.,

M. W. Philips.

Log Hall, Miss., Dec. 31, 1844.

Wax for Grafting.—Melt three parts of rosin, two of bees' wax, and one of tallow, together; pour this, when melted, into cold water, a pound at a time. Having rubbed your hands with lard, work the wax in them till it is pliable, and when the water is forced out of it, it is ready for use, and will remain on the trees for three years. Use the wax sufficiently warm to spread easy; cover the top of the stump about the thickness of a cent, and the slit, as far as it extends, somewhat thinner.

The time for grafting depends much upon the season; but the best is when the buds first begin to open. Scions will live set any time after the sap freely circulates, and till the apples are as large as musket balls.

To remove Stains.—Stains, on varnished articles, which are caused by hot water, may be removed by rubbing them with lamp oil, and then with alcohol. Ink stains can be taken out of mahogany, by one tea-spoon full of oil of vitriol mixed with one table-spoon full of water, or by oxalic acid and water. These must be brushed off quickly, and then washed with milk.

WEDNESDAY, APRIL 17, 1844.

THE BACK VOLUME.

All new subscribers who may desire it, can obtain the first volume, neatly bound in boards, at one dollar the volume.

CULTURE OF BROOM CORN.—"A Subscriber," to whom we are much indebted for his valuable communication upon the "*Culture and preparation of Indigo for Market*," in this number, in a postscript to that article, asks:—"Why may not the Broom-Corn be an object worthy the attention of Southern Agriculturists? Of this, there are several varieties, (species.) The *Sorghum saccharatum*, is cultivated at the North, not only as an article for manufacture, but for the seed, which is said to be a nutritious food for stock, when ground and mixed with the meal of the Indian Corn. Its comparative weight with the Maize, is nearly as four to five. There is no doubt it might be profitably cultivated at the South. Must we be dependent upon our Northern brethren, for so simple an article as a Broom? We should do our own sweeping upon our own terms; and without paying a stiver for a clean and comfortable floor. Whilst we are paying heavy duties to protect *their* interests, let us attend to another duty, which we owe to ourselves—to protect *our* interests by industry and economy; and we shall pay them less, and enjoy the products of our own labor."

In reply, we beg leave to remark that, in our opinion, there is no good reason why Broom-Corn is not worthy the attention of Southern planters. For, in addition to its value for food, the manufacture of brooms from the stalks affords to a considerable class of laborers at the North and East, profitable employment, in the production of an article of necessary consumption, and of which the South is a large consumer. We have often been astonished at this, but we have been so long accustomed to the culture of Cotton and Corn, while we submit to be dependent upon other sections of the Union for almost every thing else we consume, that we seem not only to be ignorant of the advantages of independence, but wholly indifferent as to the means to attain that position. It is true, there is no manufactory of brooms at the South, of which we have any knowledge; and it is even doubtful, if there were several, whether our planters would not consider it "*too small a business*" to cultivate Broom-Corn for their consumption. It is, however, equally true, that while we are large consumers of the article, we are entirely dependent, for them, upon the North and East—enjoying, too, a climate and soil equally well adapted to their culture, and possessing all the advantages for manufacturing.

FEEDING STOCK.

We commend to the careful consideration of our readers, the following letter on this interesting subject. The lavish use of provender in Kentucky, to which Mr. Lewis alludes, and the necessity for economy in the feeeding of stock of every description, applies with great truth to almost all our planters, who are all stock-raisers to a greater or less extent. They, as well as their brethren of Kentucky, have much to learn from the Eastern farmers, as well in this department of domestic economy, as in all the others to which Mr. L. refers.

From the Southern Planter.

LEANGOLLEN, KY., February 28, 1844.

C. T. BOTTS, ESQ.:

Dear Sir—Permit me to return you my sincere thanks, for sending to me two numbers, (the January and February,) of your agricultural periodical, "The Southern Planter." The people are more benefited, their real interests more advanced, their rational and moral powers more healthfully secured, by one such paper, than by all the political and polemical slang-whanging journals that ever were or ever will be expectorated on them. Agriculture is gradually ceasing to be a mere empirical practice. It is rightly becoming an enlightened art, founded on science, and the time will surely come when the treatment of land, crops, stock, &c., will be founded on well ascertained and established principles, deduced from facts. In feeding stock, we err widely, and commit great waste of food. If we observe the horse, cow and sheep, for instance, when permitted, unrestrained, to gather their own food in spring and summer, we may learn truths, which we should apply to them when dependent on us for their supplies. We cannot doubt that their instincts direct them aright as to quantity and quality; for we see that they grow and thrive where there is an abundance of those plants which they select. The green leaves and seeds, both immature and ripe, constitute their food. In these the larger portion is water; yet they drink and also seek salt-licks. The bodies of the mammalia, including man, contain seventy-five per cent. of water; yet, we do not attempt to assimilate their food to green grass, but feed them on dry hay or straw, and dry seeds. And the consequence is, that they do not grow or fatten so well, unless such quantities are given that a great portion passes undigested; irritating the alimentary canal, and often causing disease. Besides, these animals will not eat enough *dry* hay or straw to give the proper degree of distension to the stomach for digestion and assimilation, without the danger of producing inflammation or other injurious effects, when expanded in the stomach by *heat* and *moisture*. This should be done at least by the latter before it is eaten. Much of the *hard, dry* grain, given to these animals, so different in its condition from that which they gather for themselves, is neither sufficiently masticated nor moistened on entering the stomach, to produce its normal effect. One half the usual quantity, properly prepared, would benefit them more, and all the rest would be saved. Just so much *nutritive matter* as is contained in the quantity of good rich grass, eaten by one of these animals in a day, should be diffused in as much finely chopped hay, straw or fodder, as the animal will eat in the same time, sufficiently moistened some hours before it is given, (the longer the better, provided that it does not ferment or turn sour.) I do not confine the beneficial effects of this method to the mere mechanical effect of the water in softening and distending the mass. The most important effect, I believe, is produced on the elements of the water itself; one of which enters largely into the composition of flesh and fat, (hydrogen.) We know that cows and sheep will thrive when fed on turneps and straw, yet turneps contain 92½ per cent. of water, according to the analysis of Mons. Boussingault, an accurate chemist; and when compared with Indian corn, 138 parts of the latter are equivalent, in nutritive matter, so called, to 1,335 of turneps. The decomposition of water, and the appropriation of its elements, by the organs of nutrition, I believe, to be greatly facilitated by mixing vegetable matter with it: if so, we *gain* one of the important constituents of flesh, fat, &c., from the water. And this is certainly cheaper than to get it from rich, oily seeds, the proceeds of laborious cultivation. This is not a mere conjecture of my own. Count Rumford entertained the same opinion, and so do Drs. Prout and Pereira. (Treatise on Food and Diet by Jonathan Pereira, edited by Chas. A. Lee, New York, 1843, p. 40.) It is well known that gold and silver fishes, and others also, will grow and fatten on water alone. It may be said they obtained their nourishment from *other substanees* contained in the water, and not from the water itself. This would not alter the case, for the water mingled with the food of stock contains also these other substances, while haddock has in its composition 82 per cent. of water; carp, 80.1; and trout, 80.5; according to the authority of Brande and Schlossberger. Now, this greater quantity of water in fishes than enters into the composition of the mammalia, it is fair to attribute to the water itself, on which they seem to live.

The *mill*, the *straw-cutter*, and *water* are, in my opinion, the indispensable auxiliaries of those who would feed their stock in the best manner and most economically. We have mills here which grind up unshelled ears of corn. A slight alteration in the common corn grist mills, adapts them to this purpose, without interfering with their fine meal making use. The eye of the upper stone, instead of being circular, is enlarged on one side, and a removable tube, large enough to admit any ear of corn, is thrust into this side enlargement. Into the lower stone, beneath the end of the tube, two knives are fastened, so that at every revolution of the stone, the ear of corn is swept round over these knives, which slice it up, and then grind it into meal. It is a patent affair, answers admirably, and is added to any common mill for fifteen dollars, patent included. Mr. Robert Wickliffe, of Lexington, has had lately a sort of mill erected, which grinds up oats in the sheaf or corn in the shucks. I have not examined it, but am told that it makes excellent chop, ready for moistening or feeding dry.

So you see, sir, that even in this Elk Horn Paradise of hogs, horses, mules, and corn, we are seeking out and practising more economical methods of feeding stock. You must not suppose, though, that these methods are in general use—far from it; few as yet have adopted them. After the adoption of these, another will follow for cows and hogs. The *cooking* of their food, in which there is certainly great gain.—But *our* onward course in all these matters is greatly retarded by the want of laborers, and the consequent high price paid for every kind of manipulation.

Although we are "*a match*" for the Yankees in horse-swapping, bartering, and stump-speeches, (in the latter, your real *carn-cracker* can beat the world,) yet in machinery, farm fixtures, and the economical application of labor, we have much to learn from them. The cheapness of grain, and the want of a ready market for it, is one cause of its slovenly and lavish use in Kentucky.

JOHN LEWIS.

OKRA—"GUMBO."—T. Affleck, Esq., gives the following mode of preparing this vegetable: "A large mess of okra soup, (called gumbo,) should be served on every plantation at least four days in the week, while the vegetable is in season. The pods are gathered while tender enough to be cut by the thumb nail; cut into thin slices, and with tomatoes, pepper, &c., added to the rations of meat, forms a rich, mucilaginous soup. It is planted (in Mississippi) about the first of March, in drills four feet apart, every two or three feet, if the ground is rich, which it should be."

From the Tennessee Agriculturist.

SMALL FARMS.

Perhaps the greatest mistake in the farming of America, is the practice of attempting to cultivate more land than can be well tilled. This system may be properly styled *surface culture*, and it has been the means of impoverishing more land than any other cause. In the great South-West, as well as in the South-East, thousands and thousands of acres have been worn out, and abandoned to the growth of broom sedge, by this ill directed mode of procedure. It remains no longer doubtful, that a hundred bushels of corn can be grown upon the single acre of ground, and with little more labor in tillage than is required for cultivating an acre that yields but twelve or fifteen bushels. The secret of permanent success in every thing, is to do all well that is attempted. Five acres, well prepared, and well cultivated, will produce at least as much as twenty-five acres on the common exhausting plan. Thus it is obvious, this statement being admitted, that one-fifth of the land now cultivated might, with a different system, produce as much as is at present grown in the country. It is also evident, on the supposition, that agriculture might be made five times more profitable, and assuredly the pleasure and honor of the profession might be signally augmented. *Thorough manuring, deep plowing, good seeds, timely planting, proper rotation of crops, and neat culture*, would work wonders in our Agriculture.

The intellectual enjoyment and real moral of improved husbandry, are not to be overlooked. In consequence of the loveliness of a garden, the abode of the just in the next world is denominated paradise, a garden, or a heaven, and when it is remembered the whole farm can be made as interesting as a finely cultivated garden, there is something truly enchanting in the farmer's profession. A rich and well tilled field affords the most lovely scenes; but a poor field, with an indifferent crop, is certainly discouraging.—Time will be when this subject will be duly appreciated with the farming world. T. F.

From the Albany Cultivator.

CULTURE OF COTTON IN GEORGIA.

Messrs. Gaylord & Tucker—About the middle of January, 1843, I moved to this place, which is considered, by the neighbors, the poorest plantation in the neighborhood, it having been in constant cultivation for upwards of 20 years, without rest or manure. It is poor pine land, but lies almost level, and is easy to cultivate. I very soon became a subscriber for your valuable Cultivator, and noticing Dr Cloud's improved plan of raising cotton, I was induced to try one acre. Not having the proper kind of compost, I used for broadcast raw stable manure, and in each hill half a gallon of such as I could gather in the barn-yard, and treated it throughout after the Dr.'s plan. From insects and other causes, there was 568 missing hills; from this acre I gathered 1,428 lbs. seed cotton. In August, we had a slight drouth; the cotton turned yellow, and cast a great many of the balls and squares: this, I think, was occasioned by the raw stable manure.

I also planted six acres four and a half feet by three, and put in each hill half a gallon of barn-yard manure, not having any for broadcast cultivation, nearly the same as the above; the yield was above a thousand pounds per acre. The balance of my cotton was planted in the ordinary way without manure, 3½ feet by 12 inches. From this I gathered 515 lbs. I think there was no difference in the quality of the land previous to planting. I am fully satisfied, if I had used the proper kind of compost, instead of the unrotted stable manure, and a full stand, I would have had 3,000 lbs instead of 1,428. I am so much pleased with the Dr.'s plan, that I expect hereafter to practice it as far as my ability will afford; and if I could obtain some of Dr. Cloud's improved cotton seed, I flatter myself that in a few years I would be able to astonish some of our cotton planters that adhere so strenuously to the old system of kill, cripple and go ahead. EXQUISITE IRONY—POVERTY.

As poverty is the lowest, so it is the most impudent of the whole family of vices. Pride is a gentlemanly failing, and sins sweetly and respectably. It smells of civet, and turning its varnished cheek to the sun, walks abroad in purple and fine linen. Nay, it rides in a coach and four: and, in hours of penitential castigation, bolts itself in a pew of best upholstery, and in a fit of humility, lasting at least a couple of hours, calls itself a miserable sinner. Hence, pride at its worst has its good graces. At all events, it never offends that extraordinary abstraction, public decency; for though we hear much about it, it is, nevertheless, sometimes as difficult to discover as a city police man. No, pride, being a vice that is well to do in the world, may be called respectable. Pride keeps a barouche! Drunkenness may, or may not, be respectable, according to its education. When we say education, we mean the peculiar bottle it studies. For the drunkenness that ponders over champagne, is a very different vice to the drunkenness that takes libations from pewter quarterns. Arrogance is also a vice that may have its laudation. It rarely consorts with beggars; but is, at least among that suspicious class, the respectable. Covetousness and avarice are called vices; for our part, we have ever thought them among the noblest virtues. And so, indeed, in their heart of hearts do nine men out of ten think them. And this is what they do; they give them hard names, and then, to make amends for their seeming harshness, take them to their bosoms, in the same way that a foolish mother, when she sees her baby doing all sorts of household misdemeanors, cries, "you little wretch," and then catches the child in her arms and covers it with kisses. There are a few other vices that may all of them be turned into passable virtues, if found in good company. Lust, cruelty, selfishness, each and all of these may have a pretty alias—another thrilling, musical name for the long ears of biped thistle-eaters. But there is one vice, and that vice is poverty, which all men declare to be infamous, incorrigible, incapable of amendment; a leper, a wretch, a monster, to be confined in cabins and cellars, or sent, like a scapegoat, into the howling wilderness.

A Hint to Young Married Women.—Never tell your own affairs to any old gossiping housewife. Let her appear ever so specious, so sincere, so candid; be sure to avoid her, and keep your own counsel: for the only reason she has for prying into your secrets, for insinuating herself into your confidence, is to learn that some error, some deformity exists in your family, on which she may feast with secret delight for a luxurious moment, and then share some of the choicest bits with her neighbors. Treasure this up, and act upon it, and it will save you years of mortification, if not of heart-burning and sorrow.

Scours in Calves.—Lovett Peters, Esq., in a communication in the N. E. Farmer, says he has tried most of the remedies recommended for this disease, but has found the following to succeed better than any other. "It is a half a pint of cider, and as much blood, taken from the calve's neck, shook well together, and given it with a bottle."

Blind Teeth.—John Johnston, of Geneva, says he has had much experience with blind teeth. He states that when they come out in such a way that the grinders of the under jaw press on them, the eyes are always injuriously affected. The blind teeth should always be taken out as soon as they make their appearance.

Warts on Cow's Teats.—Cows are sometimes troublesome about being milked, in consequence of their teats being sore from warts. The Mass. Ploughman recommends rubbing the teats with the juice of milk-weed, and also the application of a poultice made of grated carrot. Both may be good; at any rate they will do no hurt, but the best plan to obviate this trouble is, to cut off the warts with sharp scissors, when the cows are dry. Not much blood will flow, and the teats will heal in a few days.

Editorial Remark.—"How seldom it happens," said one friend to another, "that we find editors who are bred to the business." "Very," replied the other, "and have *you* not remarked how seldom the business is *bread* to the editors."

TURNEP SEED.

A SUPPLY of the following varieties of fresh TURNEP SEED just received, viz:

Yellow Sweedish or Ruta Baga, very fine for stock,
Large Globe Turnep, } Fine
" White Flat do. } for
" Hanover or White Ruta Baga do } table
" Norfolk do. } use.

For sale in quantities to suit purchasers, by
Aug. 30 18-tf WM. HAINES, Jr.

GARDEN AND FIELD SEED.

A GENERAL assortment of fresh and genuine GARDEN and FIELD SEED, among which are the following:
Red and White Clover,
Blue and Green Grass,
Rye and Orchard do.,
Timothy and Herds do.,
Millet and Lucerne do.,
Seed Corn of every valuable variety,
Seed Wheat,
Buckwheat and Potato Oats,

Kept constantly on hand by the subscriber, all of which are offered for sale at very moderate prices. All orders, by mail or otherwise, executed with neatness and despatch.

VOL. II. AUGUSTA, GA., MAY 1, 1844. No. 9.

AN ADDRESS,

Pronounced before the Barbour County Agricultural Society, and the Public, on the Anniversary of the Society, being the Anniversary of the Birth-Day of Washington—by JOHN L. HUNTER.

FELLOW CITIZENS:

We are assembled to celebrate the Anniversary of the Barbour County Agricultural Society, on the very spot which, but a few years since, was the residence of the Indian savage. The land around us, a vast wilderness—devoted exclusively, save a few insignificant corn-patches to his hunting grounds—now blooming with all the beauty and loveliness of Civilization and Agricultural refinement.

This rich and beautiful country, in the possession of an agricultural people, is going on to fulfil its destiny, and to carry out the will of its Creator—who makes nothing in vain—mercifully consulting, in all his arrangements, the happiness of his creatures.

Whatever may be said of other useful and honorable employments, Agriculture stands pre-eminent. Not only administering to the wants, and contributing to the prosperity of the community, but it is the basis of civil society.

"Hominum generi universo cultura agrorum saluta wis."

The cultivation of the Earth has ever, from the earliest period of the world, been held in the highest estimation, and has been the favorite pursuit of the wisest and best of men—and the field of the farmer has frequently furnished the field of battle with men on whom their country could, with safety, rely in the darkest days of distress and danger. Need I cite you to the farmer of Mount Vernon, who lives in the affections of his countrymen, and wants no monument to perpetuate his fame, his epitaph being inscribed in indelible characters on the heart of every American patriot.

Indeed, the cultivation of the Earth is most congenial to the lofty feelings and sentiments of our nature; is well calculated to restrain and subdue the passions, and exhilerate the mind, and promote the health, virtue, and benevolence of Man. It brings him in closer connexion with his Creator; makes him feel more sensibly his dependence upon *him* who gives the early and the latter rain, and who, by his kind interposition, blesses his industry with, to us, miraculous results, and fills his heart with fervent graiitude.

When man was made most pure, and God had blessed his work, a garden was the residence assigned him—where, but for the tempter, he might have continued to enjoy undefiled innocence, and uninterrupted happiness.

The American farmer has abundant inducements to stimulate him to enterprise and improvement. He lives in a free and liberal government, under wise and wholesome laws of his own enactment—is the lord of the soil he cultivates—knows no master but his own will; how important that will should be enlightened and directed by the rays of science now dawning on the world; how encouraging to make those improvements for his own comfort and independence, and for the happiness of those who are to succeed him.

And the farmer in our own section, in comparison wiih other portions of our common country, possesses no unenviable a situation; blest, as he is, with a mild and genial climate, adapted to the richest staple of the world, with a rich and virgin soil, and abundant materials round him to preserve its fertility.

If the farmer would derive the greatest pleasure, as well as the greatest profit from his employment, let him use due diligence in seeking the advantages of science. He must not only be a practical, but a scientific farmer. Not that he should be a philosopher deeply versed in the sciences, but that he should be conversant with those principles that are particularly connected with his soil, its cultivation, and improvement.

And this is greatly facilitated and advanced by the association of farmers, who have the pleasure of meeting together, to interchange sentiments, compare notes, and explain experiments, which will have the happiest effect to elicit investigation, promote an useful and honorable emulation, and arouse the talent and energy of our country.

With all that is said, says an English writer, on the advantages that have been derived from the Highland Society, which may be expected to be derived from the Royal English Society, we cordially and entirely agree; and we here repeat our firm conviction, that if Agriculture, as a science, is destined to experience a general and thorough revival, as we think it is, it will be mainly owing to the establishment of such an important and highly respectable an institution, as the Royal Agricultural Society—supported, as it is, by a host of able and practical writers, aided by such auxiliaries as the useful institutions, the Provincial Farmer's Clubs—the discussions at which are, perhaps, more than any thing else, calculated to rouse and keep alive a spirit of enquiry, and a thirst after knowledge. What may not be expected?*

And allow me to add, if the State Agricultural Society of Alabama, with its useful auxiliaries, the County Societies, met with proper encouragement and patronage from the people and their Legislatures, what might not be expected? The blessings of a high and improved state of cultivation, and a spirit of enquiry, and a thirst after knowledge, that would call forth the energies of the country and lead to a developement of her resources: for, let it be remembered that Alabama is not only a cotton growing country, but abounds in mines of gold and quarries of marble,† and coal.

Such enquiry and investigation might lead to a diversion of labor from cotton, which would diminish the amount of production and enhance the price, giving profitable employment not only to the cotton grower, but to those employed in the rich mines and quarries of the State.

Alabama, important as she is in the confederacy, should not be devoid of an honorable pride and emulation, as to fall and remain in the rear of other States, in the march of improvement.

Improvement of the soil is rapidly progressing—it has commenced where the land was most valuable and crowded with population; where necessity, the first law of nature, urged and stimulated its inhabitants to improvement to avoid starvation, or an humble dependence upon other countries for the necessaries and comforts of life. In Europe, the land that produced but a few bushels, is now made to quadruple its former productions. The soil that once but sparingly sustained a small population, is now made to supply bountifully a greatly increased population. It does appear the older the land grows the greater its production. And this all the result of science, skill, and good management: says an agricultural writer, "herein consists the pre-eminent superiority of modern agriculture, that under the disadvantages of continued culture, the soil is thus capable of maintaining its fertility." In the old States, the planters have come to the conclusion, from their various experiments on manures, that it is easier and more profitable to improve a partially exhausted soil, than to clear and put into cultivation new land; and lands which, but a few years ago, were regarded as worn out and worthless, are now estimated at a high value.

Long continued cultivation, particularly in Cotton, will, as experience teaches us, exhaust the richest and best soils. To preserve its fertility, ought to be the earnest and active desire of every farmer who would avoid a sacrifice of his property, with all expense, inconvenience and privations of emigration. Happily for us, we can now start with a soil fresh and productive, which will require less labor and expense to improve it, than to wait until it is exhausted or worn out; and we are blessed with abundant materials easily procured for that purpose. To accomplish so desirable an end, the farmer should turn his attention to a rotation of crops, resting and manuring his fields. Nature, tired of one kind of growth, shows its strength and vigor in producing another kind. The soil that bore the Oak and Hickory, when cleared and cultivated, and then suffered to remain at rest, grows up in Pines—nature teaching man a lesson for his improvement in the rotation of his crops. Too long a continuation in succession of the same plants upon a soil, is said to poison it as far as that plant is concerned, by its final exudation, as well as its drawing from, and exhausting the soil of those grasses that the plant most particularly feeds upon or absorbs—whereas the soil would be fresh and productive for another set of plants.

It is hardly necessary here, to observe the propriety of an alternate growth of fibrous and tap-rooted plants—the former deriving their food from the surface, and the latter from a greater depth. To the former class belong our valuable Indian Corn, and to the latter our Cotton plant. Cotton always shows the benefit of a change from Corn, and Corn succeeding Cotton shows a still greater benefit, as though the land had been previously manured. In our rich bottom land repeated successions of a Corn crop poisons the soil with the insect called the bill-bug, which saps the young and tender corn plant, and renders it difficult, and often impossible to set the crop. A change to cotton is destructive of this insect, and restores the land to its valuable property of again making an abundant yield.

To rest a partially exhausted soil, protecting it by enclosure from the grazing of animals never fails to produce the most fertilizing effects, most particularly in the culture of the cotton plant. Cotton, from our constant observation and experience, flourishes best upon a rested soil. It would, therefore, be greatly to the interest of the planter, to divide his arable or planting land, so as to have a portion of it at rest and alternating with the balance, and plowing in such vegetable matter, as has been accumulating on

*Great improvement in Agriculture.

†The speaker was presented with a beautiful specimen of marble from Talladega county. Coal used in Tuscaloosa.

the former in time for decomposition—for, if not in time, the crude vegetable matter will produce by fermentation a vacuum and heat which will give disease to the young and tender cotton plant.

Some agricultural philosophers of the present day, upon the new doctrine of the radical fecal exudation of plants, would explode the necessity of rest. They contend that with a judicious rotation, and the application of manure, land wants no rest from cultivation, and will not tire or exhaust. But let it be remembered that the culture of cotton differs materially from the grain* or corn crop, where that doctrine is promulgated.

The culture of cotton is one of long continuance, requiring numerous plowings and hoeings to bring it to maturity, constantly exposing new surfaces to the action of the sun. On the other hand, their grain or corn crop is generally broad-cast, and requires but little or no cultivation, after planting it, to bring it to perfection. I have known a sandy soil, notwithstanding a rotation from cotton to corn, become too porous for cotton, from long cultivation so as to admit the sun, and excessive moisture to the roots of the cotton plant, and rest for consolidation and a closer adhesion of the particles of the soil was considered the only remedy. It may be said a loose, sandy soil, was not adapted to the culture of cotton, but our experience teaches us that a rich, sandy soil, is perhaps the most suitable land for that culture.

In resting land much exhausted, it is very desirable to assist it in getting early a vegetable coat, not only to protect it from the sun, but also to add to its vegetable and gaseous accumulation. For this purpose, the Pea plant cannot be too highly recommended. First, it is well adapted to our climate and country, and grows upon land too poor to produce any other plant to advantage. Second, it does not exhaust but enriches the soil; it has small roots and large leaves, drawing more food from the atmosphere than the soil, and affords a covering from the sun. Third, it may be sown upon the land when the planter lays by his crop, an interval between that and harvest time; and as it is of rapid growth, it has time to mature.

On the subject of manures, allow me to impress upon you the advantages of marl. You truly reside in a marl district. It is in this section abundant on the rivers, creeks and branches, and from its ingredients, when it is composed in due proportions of lime, clay, animal, and vegetable matter, and marine substances, in a state of decomposition, is a rich manure as the production of the good marl soil demonstrates. But some marl has an excess of lime or silex, and will not make a good manure, without making a compost to supply its defects. Neither silex nor lime improve of itself, or conjointly a soil farther than the silex, to make it more open and less retentive of moisture, and the lime to act more as an absorbent and a stimulant to vegetable matter in the soil. Upon a worn out and exhausted soil, which is the escape in the way of gas of its vegetable matter, lime would form a most important ingredient, united with vegetable matter in a compost.

The cotton planter has a great abundance of cotton seed, which, from its oily nature, can be converted into the richest manure.

The cotton seed, if suffered to be exposed to the action of the sun and rains, looses by evaporation of its gases more than half of its value; if sheltered, would hold its germinating power, and would not only be troublesome to the growing crop, but loose much of its strength and valuable qualities. To prevent these effects, it readily occurs to the mind of an observant farmer, that it should be covered with a thick coat of lime or marl, or with a vegetable mould or earth, obtained from the branches, ponds or low grounds, most accessible and convenient, which will not only protect it from evaporation, but make important additions to it.

Professor Liebeg, speaking of volatile parties of manure, in relation to stable manure, says what will with equal propriety apply to the subject under consideration:

"The ammonia emitted from stables is always a combination with carbonic acid, carbonate of ammonia, and sulphate of lime, cannot be brought together at common temperatures without mutual decomposition. The ammonia enters into combination with the sulphuric acid and the carbonic acid with the lime; forming compounds which are not volatile, and consequently destitute of all smell. Now if we strew the floors of our stables from time to time with lime, they will loose all their offensive smell, and none of the ammonia which is formed can be lost, but will be retained in a condition serviceable as manure."

"The manure," says a writer, "produced by the farmer's own stock, naturally the most valuable, is yet the most mismanaged of all the fertilizers to which he has access. This bad management has been not alone chargeable to modern cultivators; for, from the earliest period, when man began to cultivate the earth, there is evidence that the manure of his cattle has been generally wasted, often neglected, and commonly mismanaged." Cato, the Roman, in his agricultural writings, gives admonitions to his brother farmers on this subject—he says, "study to have a large dung hill, keep your compost carefully,"—meaning, I presume, that it should be protected from waste and evaporation, by the enclosure and covering.

The atmosphere abounds with the finest and richest manuring particles provided by a kind Providence in a gaseous state for the use of plants, which descend upon the earth in the way of dew and rain. "Several chemists have proved the existence of saline matters and organic substances in the air. The falling rain carries down with it salts of ammonia, of lime, and a flocky organic matter floating in the air." Some plants absorb largely their food from the atmosphere, some from air and water, others almost exclusively from the earth, whilst all plants in general, from all these sources. By a wise economy of nature, plants absorb most freely those gases that are deleterious and destructive to the health and life of man, and emit most freely those gases that promote his health and energy. Carbonic gas derived from the atmosphere, is said to be absorbed by the leaves of plants; and nitrogen from the same source enters into the soil, and with other combinations forms ammonia, which is taken up by the roots of plants, but which is so volatile as easily to be drawn up into the atmosphere by the operation of the sun, and dispersed by the air and wind.—It should, therefore, be the study of the farmer, so to prepare and cultivate his grounds, as to preserve its attractive and retentive power for those atmospheric gases, and to give a healthy growth and action to the plants, to attract and absorb them also.

And this can be effectually done by frequent working.

Some agricultural philosophers, so infatuated with the idea of atmospheric manure, seem to think but little else is required, to preserve the fertility of a well constituted soil, than to keep it in a fit state to receive, absorb, and retain what gaseous matter may descend upon it. Of all plants the cotton is the most dependent for its growth and healthy action, as well as for the length, strength, and fineness of its wool, on the influence of the atmosphere. The sea-island cotton is well known to degenerate as you leave the sea-board, and thirty or forty miles beyond that region, although the climate and length of season may be favorable, the atmosphere will not admit of its successful cultivation, and a coarser cotton has to be substituted, commonly called upland.

We cannot refrain from noticing the prospectus in a valuable periodical published at Augusta, for the sale of a patent to make manure. The ingenious patentee, Mr. Bommer, proposes to furnish the secret and system for making manure for a garden, for the sum of ten dollars; and for a larger quantity of ground, a proportionate increase of compensation. I presume the secret lies in the use and application of chemical agents to facilitate the decomposition of vegetable or woody matter, and thereby convert raw and crude matter into wholesome and valuable manure. Matter must, after all, be the basis of all manure, and he that will not procure that matter, might as well look for manure, with as little hope of prospect, as the farmer for a crop, who neither sows the ground, nor bestows cultivation upon it. I would not, however, be understood as speaking disparagingly of any process by chemical combinations, to facilitate the conversion of crude, and otherwise indigestible substances, into a fit and suitable pabulum for plants. For instance, sulphuric acid sprinkled on calcareous substances, would form sulphate of lime, a valuable manure. So might be found other chemical agents to convert silicious or other substances, by fermentation into manure and hasten decomposition, which would tire the patience, and disappoint the expectations of the farmer, to wait for the slow process of unassisted nature.

In just referring to atmospheric manure, brings me to speak of, and to impress on you, the advantages of fall ploughing, usually denominated flushing of land, before immediately preparing it for the reception of the seed. It has, no doubt, struck your observation, as it has mine, the great benefits derived from it. It renders the land more easily managed during the growing crop, and it pulverizes clay or stiff soil by exposing its surface to the action of the frost, which, in many seasons during the crop, could not be pulverized so as to admit the setting of a crop, or the growing of the young and tender plant.

The soil, as has been already observed, derives much of its productive property from the atmosphere. Constantly to expose new surfaces to the action of the atmosphere, and to keep it in a soft and spongy state, is to give it more attractive power for the gaseous matter floating in the air, and more absorbent power to retain it when dropped upon it. For instance, "much greater quantity of carbonic gas will be absorbed by a given surface of earth, if the earth is frequently stirred, than if it were to remain with a single saturated surface;" and with a hard and imporous surface, the gases would alight upon it to be extracted and taken up by the morning sun; whereas, otherwise, they would be incorporated with the earth, and form combinations to enrich it.

Fall ploughing is very serviceable in aiding the draining of clay or stiff soils, as well as to render sandy or silicious soils subject to drought, more retentive of moisture. It renders the land less troubled with grass and noxious weeds, by more effectually burying their seeds from the action of the oxygen in the atmosphere, so essential to their power of germination. It also largely contributes to the destruction of insects. Insects more particularly, that intest cotton of late, may be attributed chiefly to the sickly or filthy condition of the plant, arising from the poverty or wetness of the soil—its exhaustion for that particular plant, by long succession of cropping, or by negligent management during the season, and the influence of the atmosphere acting upon these causes. It is true, and experience teaches us, that a particular state of the atmosphere is more fruitful in generating insects, but experience has also shown and proven, that a soil worn out and exhausted or badly prepared, and negligently cultivated, is at all times, and on all occasions, much more subject to be infested with them.

Upon all lands, more particularly those which have been at rest or recently cultivated in corn, there will always be an accumulation of grass and weeds. To turn them under by fall ploughing, allows time for their decomposition; which, if neglected until for immediate preparation for planting, such vegetable matter would not have time to rot, and in its crude state would not only be indigestible to plants, but poisonous to them. Hence, the awful necessity of burning off the trash to prevent disease, more particular-

*In England used for wheat.

* It should be Sulphate of lime, common lime

ly to cotton. I remember noticing the great productiveness of the bottom land of a neighboring planter on our river, and in conversation with his intelligent Overseer,* recollect his attributing his success mainly to the advantages of good fall ploughing.

Allow me to bring to your notice some of the obstructions to the improvement of our lands. First—temporary fencing for enclosing our fields, which wastes much valuable time in repairing them and making them over; the necessity for which so often occurs, at a time when the planter should be collecting and preparing his manure, and his fields for planting. Second—planting too large a cotton crop to the hand. One acre well prepared, and skilfully and diligently managed, will produce more than two acres otherwise. Besides, it will be more easily picked, the picker having to go over less ground, as the bolls will grow larger and thicker. With a moderate proportion of cotton in cultivation, in a fair season, the planter can produce as much cotton as he can conveniently and comfortably save and harvest, and he will be enabled to make a larger and more bountiful provision crop, to the comfort of his slaves and stock; and he will not be driven into the dead of winter, to run over his scattering cotton, when the weather is generally inclement and cold, and he can find more suitable employment of his hands to more suitable purposes. Third—the neglect of draining his lands in low places. Water may not always appear on the surface, but when not drained, if the season is not excessively dry, water will lodge under the suriace destructive to vegetation, in those spots, and aroun' them. Wet lands are unfit for cultivation, and the cotton plant particularly requires a dry soil.

In winding up, feltow citizen farmers, for I have already trespassed too long on your patience, let us come to the conclusion of the whole matter. Let the farmer study to have a large compost, give due diligence to manuring and preparing his lands; let him carefully put his seed into the ground, and let him take an early start with the young and tender plant, before the grass and weeds begin to rise, and then let him look up to his Heavenly Father, trusting in his promises to reward skill and industry, and bow with submission to his will. Although the race may not always be to the swift, nor the battle to the strong, diligent perseverance in his business will not fail to meet its merited reward, and eventually to crown his labors with success.

Gentlemen of the Agricultural Society—Allow me to congratulate you on the interest manifested in our community, on the important subject of Agriculture—the result of your persevering efforts—which, while they redound to your credit, will, I trust, afford the farmers and planters in our county increased means of comfort and independence.

Could our beloved Washington, the anniversary of whose birth-day is so appropriately the Anniversary of your Society, but witness the great improvements in that soil which his valor defended, what would be his feelings? For you all know he was a scientific and practical farmer, and took great delight in the business of his farm, and, like Cincinnatus, always regretted to leave it for public employments, although always obedient to the call of his country, and ever ready to sacrifice his private and domestic happiness to the good of his country. Unlike the great Captain of the age, who so overwhelmed with a boundless ambition, and insatiable passion for glory, as to forget the rights of men and nations; who displayed greater mental power than any man who ever drew a sword or wielded a sceptre—who disposed of Crowns and Kings, as children with their toys—who "had given him the necks of his enemies, and the hearts of his subjects"—who threatened and aspired with glory to become the world's conqueror and master. Our Washington, possessing no ordinary abilities, with the best practical good sense, and the most exalted virtue, stands pre-eminently distinguished over the great Napoleon—for the honesty of his intentions, the purity of his motives, the sublimity of his patriotism.

"His feelings—thoughts—and acts united ran
To one grand point—the happiness of man.
No blemish stained the escutcheon which he bore,
If he loved glory—he loved virtue more."

When the French Revolution closed, Napoleon, from being the Republican First Consul, assumes the Royal purple, and with great pageantry and show, is crowned *Emperor*.

When the American Revolution was closed, Washington retires from the head of the army to his farm, with the benedictions of a grateful people; the one was distracted by the cares of arbitrary Government, and aspirations for universal empire—whilst the other was devoted to rural pursuits, cultivating those finer sensibilities of the soul. Napoleon seemed commissioned by Providence a scourge to his race; whilst a Washington, a blessing to his country and mankind.

Let us ever bear in grateful remembrance the Farmer of Mount Vernon—the Father of his Country—by endeavoring to imitate his example as a *farmer* and *patriot*.

*Mr. Crow at the plantation of Preston & Nellums.

From the Mississippi Valley Farmer.

THE PRODUCTIVE POWERS OF NATURE.

The powers of nature to create vegetable productions appear never to diminish; the process goes on year after year with increasing energy, and brings forth an increase of vegetable matter to be again decomposed and returned to the soil. This is the natural process by which the decomposing vegetable matter which we find in the soil is formed; and there has been a continual succession of production, decay, and reproduction, of vegetable matter, going on ever since nature first sprung into existence, producing vegetables which, when dead, are decomposed into the elements of which they were originally formed.

No loss is sustained by decomposition of vegetable or animal matter in the soil; all is reduced to the first elements of plants, which give fresh energy to vegetation by again entering into vegetable composition.

Thus, the process of the growth and decay of vegetable matter goes on in a continual succession, and the decay of one crop becomes the nourishment of the next.

When nature is left to herself, the accumulation of decomposing vegetable matter on the surface becomes great; and if the soil is not possessed of the property of hastening their decay, the vegetable matter is merely increased on the soil, without adding to its productive powers.

On a careful examination, we think, it will be found that the production of vegetables never exhausts any soil; the yearly growth of grass, with its decay, adds yearly to its productiveness; and even a plentiful crop of woods, when allowed to decay on the land which produced them, has the same effect; and thus it is that land, which has been worn out by cross chopping, is, by slovenly farmers, left for nature to improve.

When the natural pasture is consumed by stock, it is converted into animal food for man; and the excrement of the stock being left on the soil, forms a rich decomposing animal manure, which gives to the soil increased energy to reproduce an increase of vegetable food for an additional quantity of stock.

Pasture land is full of vegetable fibre, from the surface down as low as the roots of plants descend. Some are the recent roots of grasses, others are those of every stage of decomposition. In arable land, scarcely any vegetable fibre is to be found; this circumstance should teach us, that to form a good pasture, we should fill the soil with vegetable fibre as a manure, where we convert arable into pasture land.

The very small proportion of vegetable matter which is contained in the most productive arable soils, would almost seem to indicate that their richness does not depend on the decomposing vegetable matter, but on something else; for, if all the straw or refuse of the crops it produced was returned to it after it had passed through the stomach of some animal, this would scarcely be equal to one-third of what the earth produced.

A judicious succession of crops, and a profitable consumption of the produce by sheep on the ground, returned to the soil such a quantity of manure as to give an additional means of increasing its productiveness.

"Water is necessary to the growth of plants. It is essential to the juices or extract of vegetable matter which they contain; and unless the soil, by means of commutation, be fitted to retain the quantity of water requisite to produce those juices, the addition of manure will be useless. Manure is ineffectual towards vegetation until it becomes soluble in water; and it would even remain useless in a state of solution if it so absorbed the water as entirely to exclude the air; for, in that case, the fibres or mouths of the plants would not be able to perform their functions, and they would soon drop off by decay."—179, Stewaid.

It is necessary that the animal and vegetable matter in the soil should have this decomposing disposition, and the soil have it in proportion to the proper admixture of the materials of which it is composed.

A certain degree of heat, the influence of the atmosphere and water, are necessary to carry on the decomposition of animal and vegetable matter in the soil. The best constituted soil, therefore, has the power of imbibing, retaining, and giving up to the plants a proper degree of heat, air, and moisture. When the atmosphere is warm, moist and sultry, vegetable life is in the greatest vigor, which would indicate these to be necessary to vegetable life, if not the very principles on which it depends.

Soil should not only have an affinity for the moisture of the atmosphere, but it should also have the property of readily transmitting it to the vegetables which grow in it.

The soil, therefore, which it is best adapted for retaining and transmitting, in all circumstances of wet and dry weather, the necessary quantity of moisture to growing plants, may be reckoned best and most productive.

If we impart to any soil that which induces vegetation, we improve it, and increase its productiveness; but if we in any way withdraw from it that which tends to produce vegetation, we injure it, and make it sterile. Barrenness in soil is produced when the component parts of it are so firmly united, that air, water, and the influence of the sun, cannot enter into combination with it. When a soil is pure clay, it is sterile and worthless, and so is that which is pure sand. The former resists effectually the enriching influence of the rains and dews, which merely fall on its surface, and either run off or lie there, without penetrating into it. The sun and wind also may beat on it and blow over it, but they can never penetrate its mass to awaken up the dormant energy that lies within; they only have the effect, by their repeated attacks, to dry harden the surface, crack it into irregular portions, and more firmly to lock up any languid and dormant principles of vegetable life that may be within the mass. The latter is so porous and loose in its texture, that the rain and dews no sooner fall on it, than they pass through it rapidly, like water through a sieve; the rays of the sun and the wind evaporate and dry up the last particles that remain, producing only a transitory effect on vegetation, and because they have no regular supply of moisture, the plants soon wither and decay.

The energies of the soil are frequently held in bondage by some pernicious quality inherent in it, or imparted to it, which, if neutralized or extracted, the soil would become productive.

When light, sandy, and vegetable soils, are artificially made lighter, they possess little of the principles of vegetation. The mechanical disposition of a clayey soil is also deranged by improper treatment, such as trampling or ploughing it in wet weather; and although the soil has a full supply of animal and vegetable manure in it, yet the mechanical derangemen

so totally locks up all its energies, that the fermentation so necessary is altogether stopped, and complete barrenness is the result.

This we have frequently observed to occur from land being trampled by sheep, in eating off turneps, from strong clay soil during wet weather, in the early part of the spring.

They convert the surface into a complete puddle, and when it becomes dry, the parts composing the soil are so closely united together, that it is like bricks dried for the kiln, and is entirely unfit for the production of plants. It is evident that the causes of sterility in these soils are opposed to each other; each, therefore, will require a mode of treatment peculiar to its case. The light, sandy, and vegetable soils, that are too friable, must be artificially rendered more firm; and the too tenacious clay soils must be made artificially friable, and kept so, and be pulverized and mechanically altered before we can expect them to become productive. It is evident, if these two soils could be mixed together, the mixture, with a proper quantity of vegetable and animal manure, would make a good productive soil.

From the New England Farmer.

ON THE RIGHT USE OF MANURE.

Mr. Editor—After all the conflicting opinions about the depth to which manures should be buried, if covered at all; and after all the conflicting opinions about the *time when* manures should be buried, permit me to say that, according to my experience, the depth to which manures are covered, and the degree of rottenness which manures should attain before they are used, should be varied according to a number of different circumstances, as:

1st. The difference in the component parts o the manures.

2d. The difference in the kinds of soil and subsoil to which they are applied.

3d. The difference in the kinds of crops which it is designed should be benefitted by the manure; and

4th. The difference in the time when it is designed that the manure should give forth its powers for the benefit of the crop.

1st. There is very considerable difference in the component parts of manure. Some are volatile, some are fixed. All volatile manures should either be composted, or else, if it is practicable, they should be covered as soon as they are spread, in order to prevent them from evaporating ahd flying into the atmosphere when used. But if the volatile parts of the manure are composted with peat, or other substances which are retentive of moisture; or if, according to the views of Liebig, the volatile parts are fixed by strong acids, or by the sulphate of lime, they will not then require so deep a covering as if they were not thus composted or deprived of their volatility. Composted manures do not require to be ploughed in as deep as those which are not composted. And where farmers cultivate damp soils and compost their stable and barn yard manures with peat or swamp-mud, we are assured that they sometimes succeed pretty well in the cultivation of grass, corn, wheat and rye, by leaving the composted manures on or near the surface of the soil.

Again: manures which are not volatile, but which are disposed to sink in the soil, such as lime, ashes, marl, clay, sand, &c., should be left on or near the surface ot the ground. And those manures which naturally collect moisture, may be left nearer the surface than others.

2d. Manures should be differently applied on different kinds of soil and subsoil. Long manures ploughed into a stiff soil, tend to loosen it, so as to admit more air and make it lighter.—Manures should be covered deeper on a dry gravelly soil than they should on a damp one. On a soil which is decidedly wet, the soluble and volatile parts of the manure would be likely to mix with the water, and to go off with it; while on a very dry and gravelly soil there would be more danger of losing the volatile parts of the manure by rapid evaporation, unless the volatile parts of the manure were fixed, or carefully covered. Volatile manures should be composted with peat or swamp mud before being applied to dry gravelly soils.

3d. Manures require to be buried deep or otherwise, according to the shape of the roots of the plants which it is designed should be benefitted by them. For those plants which send down long tap roots, the manure should be mixed with the soil, not only on the surface, but to a considerable depth below it. A number of years ago, I took an exhausted spot of ground, with a good, healthy, but exhausted subsoil, and after ploughing it deep, I gave it a good dressing of compost, which was left near the surface, and then I planted it with carrots. They came up and grew, and promised to make a very fine crop; the upper ends of the roots were large, but when taken from the ground, the roots proved to be very much shorter than the same kind of carrots usually were, when they grew in places where the soil was more deeply manured. But where crops are to be cultivated which send out their roots horizontally, as rye, wheat, corn, &c., and do not send them deep, the manure will produce more speedy effects, if it lies on or near the surface.

On a spot which I designed for corn, near my dwelling, I ploughed in a liberal dressing of fish offal, and lest they should smell bad, I ploughed them in with deep furrows; then manured the ground with barn-yard and stable manure, and planted corn, and my crop was only about the rate of forty bushels of corn to the acre, which was not more than I should have expected without the fish. The fish offal was too low to be fed upon much by the roots of the corn. The next year, however, I ploughed the same spot over again, with other deep furrows; this brought the remains of the fish again near the surface, and where I then planted corn, it yielded a luxuriant crop. In some places the corn yielded as much as fifteen ears to the hill.

4th. Long manures which are covered in the soil, decompose, and frequently give out their strength to promote the growth of corn just at the time when the corn is making seed, and needs it most. In this case a little well-rotted manure in the hill, to give the corn an early start, proves beneficial. But long and coarse manures do not suit parsnips, beets and carrots, and according to my experience, where parsnips, beets and carrots are planted among coarse manures, instead of their growing smooth and handsome, their roots almost invariably grow prongy, and the crop is never large. Beets, carrots and parsnips require manure which is well rotted, and ready to give immediate nourishment to these crops.

Where volatile manures are used with a view of materially benefitting crops which are to grow a number of years after the manures are applied, the manures should be worked in deep. A garden, which has been well manured and well dug, so as to work the manure in deep, retains a portion of its fertility for a number of years after the application of manure is suspended; while a soil manured with volatile manures, which are left on the surface, is soon exhausted.

A number of years ago, I buried a dead cat in a mowing field, to the depth of perhaps twelve to eighteen inches. The first year, no increased fertility was observed about the spot, but for several years afterwards, the grass grew with increased luxuriance over the grave of the cat.

This encouraged me to make another experiment. I therefore took an exhausted piece of land, which had lain in corn hills and sweet ferns, and without manure for very many years. Into this we then ploughed with fish, with good deep furrows, at the rate of 25,000 to 30,000 to the acre, and then planted potatoes. The next year we sowed it to oats and grass, and then mowed the ground for six successive seasons next following. During all these eight years the crops were improved, and during the first seven years they were very considerably improved by this one manuring. And these eight crops, after deducting all expenses for rent and cultivation, (except the expenses of removing the stones from the ground,) gave a nett profit at the rate o about one hundred dollars per acre. This nett gain was in consequence of applying the manure in such a manner as to need but a small proportional expense for the after cultivation. For, in this course, there was no expense for the cultivation after the second crop. In the six years which we mowed the grass, there was no expense but the expense of harvesting. And to have ground so much like the garden of Eden as to bring forth rich crops spontaneously for even the limited period of six successive years, without any other expense but harvesting, is not only a great advantage, but to us it was very pleasing. Had all this manure been left on the surface of the ground, we think it would have destroyed the first crops in the course, and we think the manure have then evaporated so as not to have materially benefitted the last of these crops. But to a *tenant*, who had a lease *for but one year*, it would probably have been more advantageous to have left the manure nearer the surface, and to have spread it out more extensively; yet even then we think he could not have realized any thing like the same amount of nett profit by its use.

Now then, it appears to me, Mr. Editor, that so long as the questions about long manure and short manure—the degree of rottennesss which manures should attain before they are ploughed in—and the depth to which they should be covered—so long as these questions are stated in general terms, without reference to the different kinds of manures which are used—without reference to the different kinds of crops to be cultivated—and without reference to the differences of situation, circumstances and soil on which they are grown—the debates on these subjects, (which have been going on ever since I first became an agricultural reader,) may be uselessly continued, and a large amount of ink may yet be shed in the controversy, without coming at all nearer to a settlement of these mooted questions than at the commencement;—for, unless my experience is fallacious, the degree of rottenness which manures should acquire before being used—and the depth to which manures are ploughed in, *may be varied*, and *ought* to be varied according to the various kinds of manure which are used. the various situations and kinds of soil to which they are applied, the various kinds of crops intended to be benefitted by the manures, the length of time before the manures are required to give forth their whole strength, and the various circumstances of the cultivators

I remain, Mr. Editor, very respectfully yours,
And the public's very humble serv't,
Asa M. Holt.

East Haddam, Ct., March 15, 1844.

Note by the Editor.—When our correspondent says that his eight crops (on the piece of exhausted land manured with fish,) six of which crops were *grass*, yielded him a *nett* profit of about one hundred dollars per acre, does he state what he intended to? The amount named as *nett* profit per acre, (considering that six of the crops were *grass* alone,) seems to us an over estimate—unless in our correspondent's vicinity, hay has a higher value or yields much more abundantly than with us. We think he must have erred (unintentionally) in the statement of the profit. Or do we misapprehend him?—does he mean that one hundred dollars was the total not the yearly profit?

From the American Farmer.

USE OF CHARCOAL AS A MANURE FOR WHEAT.

Dr. Lee, in his admirable address before the Agricultural Society of Erie County, N. Y., states it as a fact, that the liberal application of *charcoal* to the *wheat* fields of France, has added, *within the last ten years, one hundred millions of bushels to the annual crop of wheat grown in that kingdom.* What quantity of charcoal is there considered as a liberal application, per acre, we are not aware, but should presume that twenty bushels would be found sufficient for every practical purpose, and as we have implicit confidence in any statement of fact, which Dr. Lee would make, we feel it to be our duty to lay the

present one before our readers, in order that they may avail themselves of this meansof *restoring* any lands which they may have, that once were good wheat lands, but have ceased to be so, to a condition congenial to the product of this important crop. And that their experiments in the use of charcoal may not be expensive, we would advise all to test its utility upon an acre or two at farthest, selecting such parts of their fields as may offer a fair opportunity of producing results not calculated to deceive.

Although we do not belong to the tribe of husbandmen, who hallow things merely because they have been handed down from father to son, through a long line of generations—although we confess ourself to be imbued with the spirit which impels man onwards with the improvements of the age, still, where expense in the procurement of new manures are to be incurred, we think it safest to exercise caution in *expenditures*, as there is no class in the communities of men, where *true* economy is more needed than among farmers; for, with very few exceptions, profits are only to be attained by them by the pursuit of that enlightened system of management, which husbands means, without denying to the soil any of the appointments essential to the development of its capabilities, the melioration of its condition of fertility, and the amendment of its texture.

A leading object in reverting to the use of *charcoal*, as an improver of wheat lands, and in arraying before our readers the emphatic fact stated by Dr. Lee, springs from the hope that some of our numerous subscribers may be induced to try its efficacy upon the now growing crops. It is still time to make the experiment, and surely, if the advantage to be derived is as represented, with regard to the enhanced product of France, the strongest inducement is held out to every wheat grower, to subject a portion of his lands in wheat, to the sure and unerring test of experiment. Should any make such experiments, we respectfully ask them to permit our paper to be the medium of communicating the results to the public.

We do not affect to know what are the precise action of charcoal, and it may be premised, that even those who have an intimate knowledge of the science of chemistry, could not undertake to decide upon the question at issue. What we do know of charcoal, is calculated to impress us with a very high opinion of it as an agent of fertility. We know that if it be incorporated with animal or putrescent manures, that it exerts a most powerful economy in preventing the escape of the fertilizing gases: we believe that when applied in sufficient quantity, it will arrest, or rather prolong, the process of decomposition; thus continuing to a greatly extended period, the capacity of such manure as a fertilizer. If we approach a dung heap which is in a state of rapid decomposition, our sense of smell at once detects the escape of the volatile gases, which sensibly fix upon the susceptibilities of the olfactory organs. But if we mix with this decaying mass, a quantity of charcoal, though the decay may still go on, it will be at a greatly retarded rate, and from the affinity possessed by the charcoal for the ammonia eliminated by the carbonizing bodies, the pungent odour will be no longer perceptible to the senses, as it is seized upon by the charcoal and held in a state of fixedness. So also, if we go into a close stable, the same effect will be visible; but let the floor of that stable be strewn with charcoal or gypsum and, in a very short period, the unpleasant odor will cease, and for the simple reason, that the ammoniacal gas has been absorbed by the charcoal, and diverted from its natural tendency to ascend and become mixed with the surrounding atmosphere.

It is maintained by some of the most scientific writers upon the subject, that the decomposition of all bodies, whether of fresh manure, or of organic remains in the soil, is produced by the operation of *combustion*—a combustion similar in character, though infinitely slower, to that produced by fire. Now, we profess to be believers in this doctrine, and hence we infer, that the peculiar use of charcoal, to consist in its competency to absorb and retain within itself for a considerable time, those fertilizing gases which are produced by the decomposition spoken of, and which, by the by, constitute the very essence of all putrescent manures—the very life and spirit which supports, to a considerable extent, the growth of plants.

It has been a remark, justified by the observation of the best informed farmers, that *new grounds*, where their mechanical texture is adapted to the growth of the wheat plant, are most favorable to its culture and product; and that such grounds, in a series of years, cease to be so—Why is this so? Is not the inference fairly deducible from the facts stated, that it is because by cultivation; by the letting in of the warming influence of sun and air, the decomposition of the vegetable constituents of the soil has been brought about, and that owing to the escape of the ammoniacal gases, by evaporation, and the appropriation of them by the successive crops to their uses, that the earth has become so exhausted of its vegetable pabulum, that the sustaining principle exists in such minute proportions in the soil, as to no longer furnish to the cultivated plant its requisite quantum of nourishment to carry on that healthful and vigorous expansion of the system of roots and stems so essential to the perfection of the grain.

If we are right in our conjectures, it would seem to follow as a natural consequence, that where the land has, by culture, become deprived of its carbon, or the material for forming it by *combustion*, that the husbandman should set himself to work to supply the deficiency; and if this be admitted, there can be no better mode adopted than by the application of pulverized charcoal. It is admitted by most competent minds, that soils *abounding in vegetable remains* are more competent to attract *moisture* from the atmosphere than those which have been deprived of them. While the many admit this fact, but few, if asked the question, can tell you why they are so. But agricultural chemistry comes to our relief and solves the question at once. It tells us, that lands constituted liberally of such remains, possess the capacity of absorbing this moisture, or, more properly speaking, of absorbing and retaining the ammonia which floats in the air, and forms a constituent property of all snow and rain; and that this *capacity* is imparted to the earth by the carbon produced by the combustion of vegetable remains, or in other words, by their decomposition and decay; and that, in proportion to the quantity of matter bearing a relation to charcoal existing in the soil, so is its power to absorb and retain regulated.

We know, that lands, which have been exhausted by injudicious culture, have been restored to fertility by the culture of clover and the application of plaster, and that so soon as we can get them to sustain a good stand of clover, so soon may we date their meliorated condition. These facts go to establish the truth of our doctrine; the clover-ley turned in furnishes both carbon and ammonia, while the latter not only seizes upon the latter as it is produced, gives it fixedness, attaches it to the soil, but appropriates to the use of the plants that also which floats above it in the atmosphere, and descends, as we have before remarked, in the rain and snow. If this were not true, it would be impossible that so small a quantity as a bushel to the acre, could exert the immense power that it does. We do not pretend to affirm, that the powers of attraction and condensation, possessed by plaster, are its only powers or uses, but we may, in all modesty, claim this as among its most potent agencies.

From the course of our remarks, it is obvious that the action of *charcoal* upon any lands adapted to the culture of wheat, must be eminently beneficial; and from the circumstance of its being difficult, if susceptible at all, of solution, that when once applied, it will exert a wholesome influence for a long series of years; and hence, that it would prove not only to be a lasting, but a cheap manure.

We have thought much upon the subject, and we have come to the conclusion, that each farmer would find it to his interest, every year to mix charcoal with his long manure before he carts it out upon his fields, as in so doing he would prevent the loss of a considerable portion of the most valuable of the constituents it possesses—we mean the fertilizing gases, which, by heat and moisture, are generated, thrown into the air and lost.

From the Albany Cultivator.

MISSISSIPPI—HER AGRICULTURE, &c.

PRIVATE CORRESPONDENCE.

We have, within the last few days, received an ample package from our friend, M. W. Philips, M. D., the able senior editor of that excellent Journal, "The South-Western Farmer," published at Raymond, Miss. It is rarely that we have been more interested than in the perusal of the several papers, and we regret that the strict injunction, "not to print," will prevent our readers sharing with us in the pleasure which the life-like sketches of domestic custom, as well as of men and things in that portion of the South would have given them. A few extracts, however, are permitted, and will be found below and in our next. It is evident the spirit of improvement is abroad in the South, and the advance, within a few years, has been truly great. Indeed, it could scarcely have been possible it should have been otherwise, when such men as Philips, Affleck, Cloud, Fanning, and a host of kindred spirits, took upon themselves the labor of enlightening the public mind, and, in their own practice, giving an example of what a more skilful method of culture could accomplish.—There is much yet respecting the South that is misunderstood. Its capabilities and its productions have been decided upon, more with reference to the sea-coast, or that of the gulf, than its vast and fertile interior. A few such men, however, as Dr. P. with his perseverance, taste and intelligence, scattered over that region, will, by the influence of their writings and their examples, correct and expand a vitiated and limited public sentiment, and give to agriculture and horticulture their proper place in the pursuits and aspirations of the planter. Care will take the place of negligence, economy that of improvidence, and comfort, a word that embodies so many associations delightful to the lover of nature, will become more common than it now is. We give the extracts for the truths they contain, and to show what an observing, intelligent man, who is willing to devote the rich gifts God has bestowed to the benefit of his fellow-men, can accomplish:

"We are too improvident in all the South, to enable us to enjoy the real pleasures of the climate we live in. There are many who have little else than hog and hominy all the year, who are able to afford better living, if property be a test. There are numbers, with good estates, that have no fruit excepting a few peaches. The majority of my people, I do very believe, would look upon the Dahlia as a noxious weed; the Cape Jessamine as a worthless shrub, and if it could be that a noble Camelia were standing in a field where a plough could run, even in full bloom, that it would be cut down and cast into the fire with as little compunction of conscience as if it were a sassafras or box elder. They are unable to see any beauty in the noble steed, stately cow, happy hog, farther than they contribute to the making of cotton. Yet, with all this, there are redeeming spirits enough in the land to make one love his fellows. They are the right sort of material to make good farmers out of; they are beginning to see beauty in all things that a beneficent Providence has given excellence to; and I look for the day when our people will build and plant, rear and nourish, with reference alike to the useful and ornamental."

"Although I have been in Mississippi since 1830, (my native place being Columbia, S. C.,) I have seen comparatively little of the State, as I have found full employment at home. I can then, therefore, say little as regards fruits, shrub-

bery, or flowerc; yet a residence of two years at Philadelphia, one of the most favored Northern locations for fruits, will enable me to speak of the comparative excellence of Northern and Southern fruit with some confidence. The best peaches, melons, and figs I ever saw were in the South; the first and last in Mississippi, and with a single exception, the best of melons also. The best pear I ever ate was in the house of "Harry of the West;" the best apples were from Northern regions. I have found as good summer and fall apples South, as I ever did elsewhere, and excepting that one pear, the sugar, I have seen no finer than in Carolina; whilst the plums, I think, could hardly be beaten anywhere, that I ate in South Carolina. And flowers—here is the land for this beauty of all beauties--a woman and a horse excepted—and they only because the noble intellect governs. The pride of the forest, the Magnolia, grows here in all its majesty; many flowers that with you require protection, pass out of doors our winters—many that require considerable tact with you to propogate, can be cultivated here by any little urchin. But to return to fruits; there are too few fine varieties of fruits in this region. I know of no gentleman who has any varieties of grafted apples or pears that are in bearing save one or two. One gentleman near Vicksburg has some fine pears, and Mr. Hatch assured me they are equal in quality to the same variety at the North, but they ripen much earlier. I have now some twenty-five or thirty varieties of the apple and pear, and shall put out this season at least fifty more. My reason for going so extensively into variety, is to be certain of some that will do well. I have some ten varieties of the cherry, five of the strawberry, three of figs, and three of raspberries. Of peaches I know not yet what I shall have, as, besides budded and Northern fruits, I have some two hundred and fifty seedlings three years old, and two hundred more I shall put out this spring."

—

LETTER FROM THOMAS, AFFLECK, ESQ.

We give below some extracts from a most interesting communication received from our friend Mr. Affleck, of Ingleside, Miss. The extracts relate to topics of interest at the North as well as the South, and will aid in throwing light on the productions and modes of culture in that fertile section of the Union. The doubts which have existed as to the capability of the South to produce its necessary provisions, or to grow the principal varieties of Northern fruits, doubts which had arisen more from the neglect of the planter, than any other cause, will soon be dissipated by the example of a few such men as are now engaged in enlightening that section of the United States as to its capability and true policy.

Mr. Affleck has transmitted to us two specimens of cotton in the seed; one a specimen of good Mexican, and the other a specimen of that shown by Dr. Lovelace, at the Adams County Fair, Mi., and supposed to be a hybrid between the Mexican and some long stapled cotton. Dr. L. not having completed his experiments, did not disclose the manner of its production, but, who can say, that a more beautiful specimen of cotton than the improved, has never met our eye. and shows most conclusively, we think, what a field is open for the well-informed and scientific cultivator, in the improvement of this national staple.

"There is but one difficulty as to *pastures* and that is *none are made.* No one attempts to form pastures in any other way than by turning out fields after they will no longer produce cotton or corn, and being satisfied with the scanty crops of sedge and Natchez grass, and of briars which they may yet be able to support. Within the last year or two, however, better things are attempted. I have seen very promising woodland pasture of orchard grass; and winter pastures of Egyptian oats and rye are becoming common on well managed plantations. The cane swamps afford tolerable grazing; at all events the swamp cattle manage to grow and even fatten on the abundant browsing they find there, and make pretty good beef and capital work-oxen. These are the rams-horned, brick-colored cattle, known as Piney woods, swamp, Opelousas, or Attakapas cattle—descendants of the original Spanish stock, and yet found in those regions uninjured and unimproved. During the winter, we have no lack of abundance of feed for all kinds of stock, and, in summer, we have only to have recourse to Bermuda grass, to keep every thing *seal fat.* This is the most nutritious grass I have ever seen, and where exposed, the most closely grazed. It resembles *Nimblewill,* (Triticum repens,) but is more delicate in its appearance, leaves much more numerous and narrower, stems small and solid, growth rapid, and when in meadow, it does not attain a height of over twelve or fourteen inches. Yet I have seen this delicious looking grass afford, at a second cutting, between five and six tons to the acre of dried hay. The first and *third* cutting not so good. It stands so thick on the ground, and its numerous lateral leaves so closely interlocked, that a good hand cannot cut over more than half an acre per day, and has to cast aside the swarth with his foot, at every second or third cut, the scythe blade passing under and cutting the grass, without laying it over. It is a troublesome grass in the cotton field, but can be got under by a crop of corn and pumpkins, or oats followed by peas; it can bear little or no shade. It is invaluable for coating enbankments, and is of incalculable benefit on the levees of the Mississippi. It is stated upon good authority, to be "the Doul grass of the middle provinces of Hindostan." Whoever brought it to this country, is as deserving of a monument to his memory, here, in the South, as is Parmentier in France.

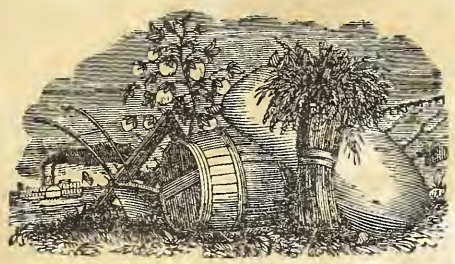
"Within some three or four years, another creeping grass has made its appearance here, said to be a native of and abundant in Cuba, and is rapidly spreading; that suits their upland, and thrives better there than *Bermuda,* and is green and grows all winter, whilst the other is cut down by the first frost. I am now using it in my garden and grounds for edgings, grass plats, &c. and think it will answer well, as being easily kept within bounds, of a dwarfish growth, forming a close sod, and remaining green summer and winter From the reports of Dr. Philips and others, it would appear that in the *Musketo,* a Texian grass, we have another valuable resource, particularly for winter pasture. Dr. P. presented me with a small quantity of seed, which is in the ground."

"You see how I ramble along! I will now return to my forgotten text, *Sheep in the South.* You are right.—"the old notion of the impossibility of growing good wool at the South, is giving way to the evidence of facts." The doctrine that all wool-bearing animals, except the negro, have their wool, in a very short time, turned into hair in the South, is also exploded. True, the common sheep of the country, bred in-and-in for generations, and ranging now in miserable burnt-up pastures, and again in the cotton fields, where they become excessively fat on the tender *winter grass;* the one season shorn, and the next allowed to surrender their coats to the briars—such sheep have thin, scanty, hairy fleeces. But they form no criterion. Are there no such animals elsewhere, 'bred by, and the property of nobody in particular, the United States over?' Why is the coat of the black-faced sheep of the mountains of Scotland, so coarse and hairy, whilst that of the Merino of Spain and of New South Wales, where they scarcely ever see frost, so fine in its staple? I feel satisfied of one thing, that the finer and more spiral the staple, and the closer and heavier the coat of wool, *and the greater the abundance of yolk,* the better will the wool on the sheep's back resist the injurious effects of the sun. Sheep are kept by the planter, in almost every instance, for the mutton alone; some few manufacture the scanty crop of wool. The mutton is *very* fine, *almost equal* to that of the mountain heather fed sheep of my native country—and that you know, is a great deal for a Scotchman to say! The native sheep of which I speak, are remarkably full and broad in the loin, and the saddle is of course proportionably good.—Sheep seem to me always to be in good health here—one never hears of the halt of a large flock dying off within a few days, as is by no means unusual in colder countries, where numbers have to be penned together for a considerable length of time.

"We have thus, you perceive, no scarcity of *beef and mutton.* Many planters in Mississippi are now making their own pork, or are exerting themselves to do so. In the neighboring County of Jefferson, this is more particularly the case. I know of several there, who last season killed and cured from 100 to 200 head; one who killed 350, and another over 700 head, all for their own home consumption. The gentleman last alluded to, assured me that all his hogs were fattened entirely on peas. which were planted between the corn rows at the last tending, and the hogs turned in on them after the corn is gathered; finer bacon I have never eaten. This gentleman has killed his own pork ever since the second year of his farming, some thirty years; tans his own leather, makes his own shoes, harness, &c., wagons and farming utensils; manufactures much of his winter clothing, and this without allowing himself to be influenced by the high or low prices of cotton, though, of course, when cotton brought 15 to 25 cents, he was, to all appearances, sinking money in employing his hands any where else but in the cotton field.—However, the best proof that his system was the true one is, that he is one of the wealthiest men in the country, living in the greatest comfort, his family settled round him, and his negroes comfortable and happy.

"You speak of being 'anxious that some one of your Southern friends would try the experiment of sowing corn broadcast, as an article of food for animals, to be used for soiling during the summer, and cured and fed, after being cut, to them in the winter, and ascertain what the practicability and expense of keeping animals in this way would be.' Corn leaves, you are aware, are now used extensively; but would not the stalk cured and cut into chaff, add much to the ability of the planter to feed stock, without materially adding to his expense? It would; and in my own case *does do so.* At 'Ingleside,' I feed nothing else. My farm here, only consists of forty acres of old field, which the small force I keep here, enables me to improve very slowly, the more, as to it is added five acres of garden, &c., requiring much manure. As I keep five head of horses, two mules, two yoke of cattle, from two to six cows and their calves, and some twenty to thirty head of hogs, I was forced to try some such means of making fodder, or have *blades* to haul from one of the plantations. In 1842, I sowed some corn broadcast, but the dryness of the season and the poverty of the land, prevented it doing much. I did not cut it, but the stock, when turned into the field, grazed on that patch of corn as long as there was a stump of it left. That winter I fed principally on *crab grass* hay, and corn cut and shocked Kentucky fashion—which does not do well. This last season I *drilled* several different patches of corn at different times during the spring and summer, drills from two and a half to three feet apart, and the stalks almost touching in the drill. It all did well; so well that though I had not more than an acre and a half in all, I fed my stock on it during the whole summer, passing the green corn through the cutting-box, with a proportion of one-third or one-fourth of dry fodder; cutting down and curing what was left of each patch, when the next sown became ripe enough to feed out. I have thus sufficient fodder to do me, I think, or nearly so, until oats are ripe, and my drilled corn comes in again. It must be in tassel, or tasseling, before cattle and horses at all relish it; and hogs, though they eat it greedily, *fall off* on it; for the reason, I think, that they reject all but the juice, and hang round the fence all day waiting for more. I have tried the Egyptian millet and Guinea corn, but prefer the maize.

"Pulling corn blades to make fodder, I consider the most unhealthy and unprofitable work done on the plantation."



WEDNESDAY, MAY 1, 1844.

PLOWING CORN—TOPPING COTTON.

In tendering our acknowledgements to Mr. McKee, for an account of his last year's crop, with which we have been quite interested, we desire to offer a few remarks in reference to the necessity of deep, subsoil plowing in the preparation of land for a crop, and as to the advantages of topping cotton, and its propriety.

The experience of scientific and practical men, attest most conclusively the advantages of subsoil plowing in the preparation of land for a crop, both as a preventive against the prejudicial influence of a drouth, and an excess of rain. The reasoning for this system of culture, is based upon the plainest principles of philosophy and common sense, and is thoroughly sustained by actual results. The subsoil plow, which we believe is scarcely, if at all, used at the South, is constructed for breaking the subsoil thoroughly, without mixing it with the soil.

When thus prepared, the subsoil becomes an absorbent of the extra quantity of water that may fall, which it retains to be given out by the process of evaporation whenever the absence of rain shall, in the economy of nature, render such evaporation necessary to the sustenance of vegetation. By this process, then, the planter converts the subsoil into a reservoir, which serves the double purpose of withdrawing the excess of water from vegetation in wet seasons, and from which nature will draw her supplies to sustain vegetation during the existence of a drouth. It is indeed a beautiful theory, and one which we are quite astonished has not obtained to a greater extent among Agriculturists. But the progress in improvement is onward, and we hope the day is not far distant, when the South will boast as high a state of Agricultural improvement as any section of the Union. To do this, however, one of the first subjects which should engage the attention of planters, is, *how they can cultivate less land*? This is a very important question, upon the successful solution of which, depends the progress of improvement, because it strikes at the root of the evil of which we complain. The effort to cultivate a great quantity of land, not only forbids, but positively prevents, the thorough preparation of land for the culture of a crop: and hence, a system which is begun in imperfections is carried out, resulting in immediate loss to the cultivator himself, and prejudicially to the general prosperity of the country. It is because of this hurry and confusion in the culture of so much land, that our lands are so imperfectly prepared: hence, few, if any, can obtain their consent to make the experiment of cultivating less land, and doing that in a proper manner.

In our opinion, when the land is thoroughly broken as we have suggested, with the subsoil plow, (which should be begun, and, if possible, completed, prior to planting, though the breaking between the rows might, in an emergency, be done after planting,) the subsequent culture of the crop should be almost exclusively a mere surface dressing—which, while it would effectually eradicate the grass and weeds, should by no means disturb the lateral roots of the crop. This surface-dressing also serves, by levelling the land, to diminish the exposure to the sun, and consequently lessens evaporation, which is also very important. Late plowing, particularly if deep, we regard as a dangerous experiment always, and rarely, or never necessary, when the land has been properly prepared in the outset of the crop. It is true, as in the case mentioned by Mr. McKee, it sometimes succeeds well, because the rain came at a proper period; but, in the absence of a rain, we apprehend no one will question that it would have proved disastrous. The comparison, therefore, between Mr. McKee's crop and his neighbors, is, we think, not a just or fair one, for theirs wanted the proper preparation of the land in the commencement of the crop.

The subject is however replete with interest, and should engage the earnest consideration of Agriculturists at the South, where improvement is so much needed; but as our limits will not permit us to-day, to enter more fully upon the subject, we must pass to the consideration of the propriety of topping cotton—upon which there are, we are well aware, very opposite opinions.

Without an opportunity of testing the truth of our own views upon this subject, by actual experiments, we incline to the opinion that its propriety should always be determined in reference both to the character of the land for richness, and also to the season, whether it be wet or dry, facts upon which the planter must determine at the time. In very rich lands, or wet seasons, where the growth is very luxuriant, running pretty much into stalk, without sending out lateral branches, we regard topping as a very necessary process; but on the other hand in poorer soils, and a dry season, we think it doubtful whether it is ever needed. Of the necessity of the process therefore, the practical planter will of course always determine, and in our opinion what might be very advantageous in one season, whould be prejudicial another, even in the same land. Upon both these subjects however, we should be much pleased to have the views of our friends, and hope they will not withhold them.

Jasper County, Ga., April 8th, 1844.

Mr. Editor:—I submit to you a history of my crop of last year, which I desire you to give a place in the Southern Cultivator, if you think it worthy.

I cultivated 150 acres of land, all fresh except 25 acres, which was worn. There were ten hands employed in its cultivation. The mode of culture and the result, I will give you in detail, and are as follows: I was so late in the commencement of my crop, that I had only 8 acres broken on the 18th of March, my object being to manure as much as possible. I was compelled, for want of time, to manure in the drill as I planted, though but little was applied to the corn. I planted my corn by running furrows each way three feet distance, dropping two grains in a hill, and covered by running two furrows, one on each side, with a very small plow, and immediately broke the land between the rows. I then planted my cotton in drills three feet distance. In the drills I strewed my manure, which consisted of killed cotton seed and manure from my lot. I worked the corn and cotton successively once in three weeks, with the plow and hoe. The first and second working of my cotton, I only run round the plant; but, in chopping out, or thinning, I was careful not to chop so deep as to disturb the manure. My last thinning, which followed my second plowing, was done principally by hand.

My corn received the last plowing and hoeing about the middle and last of June, when it was in the boot. This last plowing was more shallow than those preceding, and more distant from the corn. After this plowing, I had some dirt drawn to the plant to kill the young grass which had escaped the plow.

The result of the corn crop was, a fine crop of fodder, and 420 barrels of corn, most of which was measured.

The cotton received its last working about the 5th of August. I put no dirt to the cotton, except to cover young grass, and to replace the dirt which had been taken away in removing the grass or weeds. I topped all my cotton, except a small part which was accidentally left, which gave a striking demonstration that the topping did no good; for that which was left, bowled equally as well as that which was topped.

The result of the cotton crop was 48 bags, averaging 420 lbs.—the weights of which I have now before me.

There was about an equal portion of land in cotton and corn—say from 70 to 75 acres each.

There are two circumstances which I wish to mention. They are these: Never cease plowing in dry weather, and not to risk thick corn, if planted late. There commenced a drought on the last of April, which lasted six weeks—the unbroke ground became hard; even that which had been broken was dry as ashes, and seemed to threaten devastation to the famishing corn. Many of my neighbors desisted, for the two reasons, that they did not wish their lands broken in clods, or the roots of the corn broken while the ground was so dry. Though being firm to my purpose, I continued to plow as effectually as my feeble means would permit: the consequence was, that when the rain came, it found my ground well pulverized, and clear of grass and weeds, and a most flourishing growth ensued. As regards the third case, after I had planted all my corn crop, except six acres which lay immediately adjoining the first planted, corresponding, in every respect, with the other land, the omission or delay being on account of wet weather for the length of about twenty days; it was all treated alike as to work, and each grew

alike well until the time of earing, when there came a drought of three weeks.

The older corn remained green, while the other fired some four or five blades high. There was only four or five feet distance between the two plantings; and, being alike in all other respects, except that some of the latter contained two stalks to the hill, (though the principal part of my crop was thinned to one stalk,) I imputed the prime cause of the firing to the late planting. If the drought had continued, it would have proved a failure; but, as the rain came in abundance, it eared very well.

Yours, &c., LEWIS McKEE.

WORTH ENDURING.—Carlysle, in his last work, says: "Beautiful is it to see and understand that no worth, known or unknown, can die even on this earth; the work an unknown man has done is like a vein of water flowing hidden under the ground, secretly making the ground green; it flows and flows, it joins itself with another vein and veinlets; one day it will start forth a visible perennial well."

CURE FOR CANCERS.—The Maine Cultivator says: "A gentleman who has, for some years, been afflicted with a cancer on his face, informs us that, after having followed the prescriptions of some of the most skilful physicians, at the expense of more than seven hundred dollars, having twice had it cut, he has been effectually cured by simply bathing it three or four times a day with brandy and salt. Those afflicted with these virulent ulcers, will do well to try it.

☞Witherspoon says: "Men may talk in rapture of youth and beauty, wit and sprightliness, and a hundred other shining qualities; but after seven years' union, not one of them is to be compared to good family management, which is seen at every meal and felt every hour in the husband's purse."

☞Patient industry accomplishes wonders. A little done daily makes much a year.

SUGAR VINEGAR.—To each gallon of water add two pounds of brown sugar, and a little yeast: leave it exposed to the sun for 6 months, in a vessel slightly stopped.

☞The heart that soonest awakens to the flowers of life, is always the first to be wounded by its thorns.

☞Take every opportunity of setting an ornamental shrub or choice fruit tree about your house or door yard. Now is the time. If you have any taste, you will always rejoice at what you have done.

☞Give sheep pine boughs once or twice a week; they will create appetite, prevent disease, and promote their health. So says "The United States Complete Practical Receipt Book."

☞Never choose a woman for a wife who has thin lips and a sharp noise—except you want a *scold.*

☞Agriculture was the first, and should ever be the most esteemed of all pursuits. How happy would it be for hundreds and thousands of our young men, if they could be persuaded that a few acres of ground are a better capital than as many thousand dollars procured by writing their names at the bottom of a negotiable note; and what years of misery might be saved if men would believe that a dollar actually earned as by farmers and mechanics, is worth a hundred in prospect to be gained in trade and speculation.—*Saturday Cour.*

MEASURING CORN.—Hunt's Merchants' Magazine, gives the following rule for measuring corn in cribs, wagons, boats, &c.

"Multiply the length by the width, then by the depth. The product multiply by 4, which will give the contents in bushels shelled. To get the bushels in the ear, multiply by 8. In either case cut off the right hand figure, which is the fraction.

EXAMPLE.

Length,	20 ft.	20 ft.
Width,	10 ft.	10 ft.
	200	200
Depth,	7 ft.	7 ft.
	1400	1400
	4	8
	560,0	1120,0
	Bushels shelled.	Bushels in ears.

From the Worcester (Eng.) Chronicle

SIXTY BUSHELS OF WHEAT TO THE ACRE.

We state the following fact to show what may be done by proper management. Henry Workman, Esq., Solicitor of this Town, planted about an acre and three perches of ground with rather more than a bushel and a half of the red cluster wheat, furnished by Mr. Robert Beman, of Lenchwick, and the produce is 20 bags or 60 bushels to the acre! The seed was set by the hand, that is, it was dibbled. The land upon which this extraordinary crop was grown is known to be as good for cast as any in the Vale of Evesham.

TAKE GOOD CARE OF THE LAMBS.—A good shepherd may be known by the number of lambs that he raises. If any should die, don't throw them up on to the roof of a shed, or on to a tree, to poison the air, but skin them, give the flesh to the hogs, and save the skin. The most delicate gloves are made of young lambs' skins, and they are an article of considerable trade in some parts of Europe.—*Maine Farmer.*

HOARSENESS.—One drachm of freshly scraped horse-raddish-root, to be infused with four ounces of water, in a close vessel, for two hours, and made into a syrup, with double its weight in vinegar, is an approved remedy for hoarseness: a teaspoonful has often proved effectual; a few teaspoons, it is said, have never been known to fail in removing hoarseness.

BROOM CORN—Is much cultivated on the Connecticut river, in Massachusetts. The amount produced on the acre is from 800 to 1000 lbs., besides 60 or 70 bushels of seed; the bush is estimated to be worth four or five cents the pound, and sometimes ten or twelve cents. The seed on an acre, at 33 cents per bushel, is said to be equal to a crop of oats. Thirteen hundred acres of this plant are cultivated in the town of Northampton and vicinity, the brush and seed of which is valued at $100,000 annually. The adjoining town of Hadley manufactures brooms to the value of $160,000 annually. One person, it is said, makes 80,000 brooms a year. The process of cultivation is like that of Indian corn.

FARMING OPERATIONS.—Get your carrots forward, and try Rowland's Macassar if the crop looks unpromising. Plant your potatoes with salt, which gives them a relish; and dress with bits of woollen cloth or shreds of old coats, which will improve the potatoe's jacket. Now, sow your P's; keep your U's warm; hive your B's; shoot your J's; feed your N's; look after your potatoes' I's; and then take your E's.—*Punch's Almanac.*

LOVE OF FLOWERS.—A love of flowers is one of the earliest of our tastes, and certainly one of the most innocent. The cultivation of flowers, while it forms an elegant amusement, is a most healthy and invigorating pursuit. Unlike hunting, fishing, shooting or similar rural amusements, it inflicts no suffering on any of the animal creation, and merely aids nature in her efforts to make the world beautiful to the eye, as the fruits are pleasant to the taste. The flower garden, while it agreeably occupies the time, does not impose a heavy tax upon the pocket, and there are very few flowers but what may be cultivated to as great perfection in the garden of the peasant as of the peer. It is a taste, too, which is well adapted to the female character, and affords much rational amusement to the recluse, who by choice or chance is separated "from the crowded haunts of men, in busy cities pent."—*Manual of Gardening and Complete Florist.*

TURNEP SEED.

A SUPPLY of the following varieties of fresh TURNEP SEED just received, viz:

Yellow Sweedish or Ruta Baga, very fine for stock,

Large Globe Turnep, } Fine
" White Flat do. } for
" Hanover or White Ruta Baga do } table
" Norfolk do. } use.

For sale in quantities to suit purchasers, by
Aug. 30 18-tf WM. HAINES, JR.

GARDEN AND FIELD SEED.

A GENERAL assortment of fresh and genuine GARDEN and FIELD SEED, among which are the following:

Red and White Clover,
Blue and Green Grass,
Rye and Orchard do.,
Timothy and Herds do.,
Millet and Lucerne do.,
Seed Corn of every valuable variety,
Seed Wheat,
Buckwheat and Potato Oats,

Kept constantly on hand by the subscriber, all of which are offered for sale at very moderate prices. All orders, by mail or otherwise, executed with neatness and despatch.

For the Southern Cultivator.

CULTURE OF COTTON.

I propose, Messrs. Editors, to communicate to the reader of your public-spirited and valuable paper, the mode of preparing the land, and of cultivating the cotton plant, which has appeared to me, from experience and observation, the best adapted to our southern climate. And here permit me to remark, that I have long believed the system of deep plowing so generally pursued throughout the country, not only unnecessary for securing an abundant production, but positively destructive to the fertility of the soil. The labor it requires might be dispensed with, because unprofitable. The evident deterioration of the land under its operation, should induce the farmer to abandon it, and to adopt one more congenial to his true interest.

I am aware that I shall be opposed to deep-rooted prejudices. But let every system be kindly received, and soberly examined—rejected, if found to be practically unwise; and when experience has proved its utility, adopted. I am convinced that much unnecessary labor has been bestowed in the cultivation of cotton; from a mistaken opinion, that, even in soils naturally free and light, there must be a continued succesion of deep and heavy plowings until the plant has arrived fully to a state of maturity. In the sea coast districts of South Carolina, where long staple cotton is raised, and the hoe culture alone pursued, the production to the acre is not exceeded by any other section of country where the plough is almost the only implement of husbandry. Which fact has convinced me of the truth of the position I take. Another important result from this, what may be termed superficial cultivation, is, that there, fields now yielding a profitable investment have been under culture from the earliest settlement of that State, whilst the *new West* already presents to the eye of the traveller exhausted lands and deserted habitations. I am not, however, an advocate of the hoe culture to the entire exclusion of the plough. The two systems may be harmoniously united, and if the result of the year's labor, in the outset, be not fully equivalent to the production extorted from the soil by the eviscerating system; the results of a series of year's will amply compensate, by diminished expenses, abridged labor, and an improved country.

Supposing the field to have been thrown into ridges by the cultivation of a preceding year: the first preparatory to a new crop, is to open between them a tolerable deep and wide furrow, with a broad shovel-plow of theordinary construction. Into this should be placed, with the hand, the stalks of corn or cotton, if there be any of the growth of the previous year. The superficial soil, with whatever vegetable matter there may be upon the ground, must be drawn down with the hoe, and formed into a narrow list. An acre of land not stiff and unyielding may be thus prepared by two hands as the labor of a day is work. Over this list the manure intended for the ensuing crop must be strewed, and the ground will then be in order, for the freeborn or twisted shovel-plow; by either of which a new bed or ridge can be thrown up; thereby effectually covering the manure, and leaving a single furrow between the new ridges. The whole ground is thus thoroughly broken up, and prepared for the seeds. Planting in trenches opened by the scooter plow cannot be effected without the danger of exposing to the surface a portion of the vegetable matters deposited beneath: and is moreover objectionable, from the difficulty of having the plants thinned out to the proper distances. *Drilled cotton is never properly filled*, as this must necessarily depend, for the most part, upon the judgment of the field hands, whose object is to accomplish the most in the shortest time. A very cheap instrument has been contrived for obviating all the objections applicable to trench planting. This is a dibble of a very simple construction, and may be made by any jobbing carpenter. Take a piece of seantling, of light yellow pine, 8 by 2½ inches add 4 feet long. About 10 inches from one of the ends taper it off, on each side; giving it the form of a paddle, with a handle of a convenient size for being grasped. Bevel the square end, by lines drawn 2½ inches therefrom, and let the edge at the bottom be somewhat rounded—brought down to ¼ of an inch. For a sliding-guage, to regulate the chops made by the Dibble for the distances which may be required in planting land of different qualities, cut a groove in one of the sides, 1½ inches wide, and 1 inch deep, with such an inclination, that the lower end of the gnage, at the distance of 2 feet from the centre of the dibble may be in a line with the bevel edge. Provide for the guage a lath 1½ by 1 inch, which should fit the groove closely, and of any length which will mark the various distances in plantage; to be secured in its place by small nails easily drawn. The mode of operating with this instrument will be obvious. In a comparison, as to relative speed, with the scooter, the latter is undoubtedly preferable. Under every other view however the preference must be reversed. Let the experiments be made, and I have no doubt this single instrument will supersede every implement heretofore used in the planting of cotton—corn as well as potatoes might be planted with it.

The crop should be partially thinned as soon as the plants are fully up, the top of the ridges weeded, and dirt drawn around them—with the hoe. When this work has sufficiently advanced, the surface of the ground between the rows of cotton must be cleared of the weeds and grass which may have vegetated. This is easier, more effectually, and quicker done with the solid sweep or bat-wing-plow than by any other implement of culture. It is of a triangular shape; the extreme cutting points being about 20 inches apart. Its weight does not exceed 6 lbs; and from its construction it cannot be made to penetrate but a little below the surface; is light of draught; and under the guidance of a skilful hand, may approach the tender stems of the younger cotton with the safety and efficiency of the hoe. Three courses with this will be amply sufficient to put in good order the entire space of ground between the rows of cotton if at the distance of 4½ feet. It is decidedly the most valuable implement for superficial culture that has yet been contrived.

This then comprises the whole process of cultivation—until the plant has arrived at a growth which excludes the use of the hoe by its extended branches. The sweep should continue to stir the ground by a single course until the advanced state of the season renders that work no longer necessary. By this system, the use of the plow is abandoned after the preparation of the ground for planting. It is a system applicable to all descriptions of soil. It requires that the land be thoroughly broken upon before the seed has been placed in the earth; and under this condition only can it be pursued successfully. It lessens the labor of the field hand; and relieves the horse of that continued exertion of his strength which the system of deep plowing unavoidably requires. The cotton, when planted, is placed at such distances as the judgment of the farmer has determined the best adapted to the nature and quality of his land. There is here nothing left to the discretion of the field hand. Under such a system, I have no hesitation in affirming that lands not liable to injury by hearty showers will be improved by continued cultivation. By it, all the vegetable matter on the surface is effectually secured for the benefit of the growing crop. It would present the cheapest and least laborious plan of enriching the soil; and if commenced before the ground has lost its original fertility, it obviates the necessity of annually supplying it with manure.

I may at future time give you my views on the culture of corn.

Claiborne, Ala. A SUBSCRIBER.

For the Southern Cultivator.

Mr. Editor—The varied engagements of my farm, in which I take an active part, have not allowed me leisure until now to redeem my pledge of becoming a contributor to the columns of your agricultural paper—and even now I am tempted to an indefinite postponement, in view of my incapacity for such service. But when I look at the successive numbers of the Cultivator, see the scarcity of original communications, consider the importance of sustaining the paper, and knowing that its permanency can only be secured by adapting it to our products, culture and climate,—I feel disposed to lend a helping hand, however feeble it may be. You will not understand me as intimating that it is not now interesting and valuable—for to me it is both, the selections of which it is mostly made up being judicious and excellent. I have known for years that such a paper was needed among us, but was so foolish as to think that none but a practical farmer could conduct it advantageously. The inspection of a few Nos. not only dissipated my prejudices, but set me to work in the protection and improvement of my farm in such a manner, that I fear I would not be believed if I were to say how many *hundred dollars* I have been benefited, (in purse or prospect,) by the expenditure of one dollar per annum for your paper.

Mr. Editor, there is a large field for investigations, as to the best mode of protecting our rolling lands from washing, by means of ditching or otherwise: something efficient must be done in this respect, or all our endeavors for the improvement of our exhausted farms, or the preservation of those that are yet good, will be comparatively unavailing.

As to the best mode of producing and distributing manure;—the relative merits of the alluvial deposit on water-courses, swamp mud, and leaf manure, not only as to their fertilizing qualities, but the facility of gathering, hauling and applying, and of which, (other things being equal,) a hand will procure most per day. Will some of your subscribers, who have experience on this and other kindred subjects, please enlighten us? We need practical matter in detail: we need something to prompt us to *do*, and to be told how to do it.

The foregoing remarks and the subjoined, you may insert in the Cultivator, or reject at pleasure: I have no ambition to appear in print. I want to see, before I die, if it please God, (and I would write that name reverently,) our once beautiful country—now disfigured with bald hills and sterile plains—so improved and restored, that hopeless poverty or emigration may not be the only alternatives left our children; that the virtues which grow out of competency and contentment may abound; and that the vices springing from want and wretchedness, induced oftimes by unrequited toil, may find no place in our borders. But to the subject I had in mind when I took pen in hand, to wit: *spaying hogs*. My waning sheet forbids the intended preliminary remarks.

Pigs should be spayed early, soon after becoming inured to the change of diet required in weaning. 1st—because the operation may be performed as easily then as at any future time. 2d—should any die of it, the loss will be less. 3d—they seem less affected by it, and recover sooner. I pay no attention to the signs of the zodiac in choosing a time to spay; and having disregarded it for the last fifteen years with impunity, I conclude the popular belief in the "signs" of the times, is all the relict of an ancient superstition. My *signs* are—1st, pleasant or warm weather; because in very cold weather, pigs recently spayed may be injured by the great number of them, together with larger hogs, that pile up in the same bed. 2d—a dry pen; for if the pen be wet, the pigs will get muddy, and the operator's hands must become so, and consequently the lips of the wound; which may prevent healing by the first intention, (as surgeons say,) that is, healing without the formation of pus, and death may ensue or recovery be delayed. 3d—the pigs should be in "good order," if not fat; it is easier, perhaps, to spay a lean hog than a fat one—but any, whether fat or lean, may be spayed by an expert operator, and the fat ones recover best.

Where should the operation be performed, in the side or belly, and how performed? These are the most important matters. The advocates of belly-spaying argue—1st. That the operation is more easily performed in their mode. 2d. The place of incision is thinner. 3d. The effused blood will be more easily discharged.—The first position *may be* true, but any one capable of spaying at all, can, after a little instruction, spay in the side. This argument, too, rather contemplates the convenience of the operator than the *good* of the hog—a minor consideration, I ween. The second is true in fact—but, as will be shown presently, is entitled to no weight. The answer to the third argument is founded on the *fact*, that blood is never discharged from the cavity of the belly after the incision is sewed up, except in such cases as will terminate fatally—all effused blood being removed by a healthy process called absorption. But, (not to be tedious,) both reason and experience condemn the one mode, while they at the same time establish the other. We know, from the pendulous state of the belly, the weight of its contents must rest in part on the stitches, (in belly-spaying,) and tends to separate the lips of the wound; and, under high feeding, when the hog has so far recovered as to eat heartily, a pouch is formed, (which is of the nature of a rupture in human kind,) and is apt to injure the health, if it does not destroy the life. In side-spaying, on the contrary, the weight of the abdomen tends to keep the lips of the wound in apposition; hence, diminishes the irritation occasioned by the stitches, and promotes the healing process. In belly-spaying, an incision large enough to admit two fingers is made, and three stitches are ordinarily taken; in the side, one finger only need be introduced, and one stitch taken; and if few, or none of the muscular fibres be cut, not one hog in twenty, if well spayed, (*it is believed*,) would die without even one stitch—the muscles acting as a valve, and preventing the extrusion of the contents of the belly. Judge, then, of the comparative irritation of a large wound in the bottom of the belly, closed by means of three stitches, on which bears a heavy weight, tending (and too often successfully) to tear them loose,—and a small wound in the side, the lips of which are naturally kept in apposition, and closed with one stitch, and that one more a matter of safety than of necessity.

My mode is as follows. Having trimmed off the hair from the part, I make an incision, commencing an inch or more, according to the size of the hog, below the anterior part of the hip bone on the left side, and extend it downward far enough to admit one finger only, and deep enough to expose the muscle (the lean part) the full length of the incision in the skin: this, an expert operator will do at a stroke. The breadth of the knife blade is now placed parallel with the fibres of the muscle that is visible, (there are other muscles under it,) and gently plunged into the cavity of the belly; a finger is then introduced into the cavity through the muscles, (which separate fibre from fibre very easily,) and through the thin but strong and shining membrane that lines the cavity: this membrane is raised on the point of the finger, and the puncture in it enlarged to the size of the incision in the skin, then the *pride* (*ovarium*) is sought for in the loins, brought before the finger out of the orifice, and separated from the bag (*uterus*) by a knife: the bag is then to be traced by pulling it out tenderly until the other *pride* is found which being cut off, return the bag, introduce a finger *into* the cavity, pass it carefully all around the circumference of the wound, to be certain that the bag has *all* passed into the cavity of the belly, and not lodged outside of the membrane where it or a small portion of gut might become strangulated, and produce death. Then with one stitch only, taken with a curved needle, close the wounds. I have formerly been in the habit of passing the needle through skin, muscle and membrane; but more recently have taken only a superficial stitch, and my hogs do equally well. I use a knife, the blade of which is not more than ½ inch or ⅝ wide. The puncture made in the membrane is not so large at the point of my finger, yet the finger enters it under slight pressure: it should be enlarged so as to facilitate the return of the bag into the belly.

A Swineherd.

Covington, April 30th, 1844.

For the Southern Cultivator.

WHITE WASH.

Take ½ of a bushel of unslaked lime—which slake with boiling water—cover closely, to keep in the steam, strain through a fine sieve, and add a peck of salt previously dissolved in boiling water; 3 lbs. of fine rice flour, boiled to a thin paste; ½ lb. of sifted Spanish whiting; 1 lb of glue in a fluid state. Then to the whole mixture add 5 gallons of boiling water, stir it well, and put by, well covered, for a few days. Apply it hot, with a brush.

To vary the color, for red or pink, add Spanish brown; for lilac, common clay with Spanish brown; for a slate color, lampblack; for a redish stone color, lampblack and Spanish brown; for yellow, yellow ochre, or chrome, which is preferable. The shades of color will of course depend upon the quantity of coloring

matter added to the lime. It is said that green must not be put in, as lime will destroy the color, and the wash will crack and peel off. The above preparation is cheaper than paint and more durable than the adulterated white lead which is manufactured in this country. Its brilliancy will of course depend upon the purity of the ingredients used. A SUBSCRIBER.

For the Southern Cultivator.

MINERVA, GEO., April 23d, 1844.

MR. EDITOR—In the last No. of the Southern Cultivator, I see some very stringent remarks by yourself upon the great want of patronage to the work. Your animadversions are seasonable and correct, and no doubt flow from a pure and honest desire to benefit the deplorable condition of the cultivators of the soil. I am one of this class of men: but, from an intimate and somewhat lengthy acquaintance with this class of my countrymen, I am by no means startled at the meagre list of your subscribers.

The history of our country furnishes ample testimony of the united and laudable efforts of mechanics, manufacturers, and gentlemen of the learned professions, the object of which is to benefit mutually the whole body. The great benefits they have sought, and obtained, by uniting themselves into well organized bodies, are too conspicuous for any comment. Many advantages have been derived from the united efforts of each member of the body of society. In these associations, each member throws his little mite into the general fund of knowledge. But who ever heard, (till late,) of a well organized society of planters in the South? The subject with us is yet in embryo: deep-rooted prejudices, and long standing habits, to follow in the old beaten track of our forefathers, will require time, patience, and much perseverance, to overcome. As a public journalist, I fear you will "become weary in well doing" too soon for our good. But permit me to say, press on; the prize is *ahead*. Many fields in Houston county, the place of my residence, for years past have been much exhausted; and, although contiguous to large beds, and deposites of the richest calcareous marl in nature, (with a few single exceptions,) no planter has yet availed himself of the advantage of applying this substance, and wonderful fertilizer of the soil, to his fields, while it lies literally at the door.

These beds of marl, by some powerful convulsions of nature, are placed in detached portions or spots, from near the Ocmulgee river to the Flint, and are in sufficient abundance to supply the whole State of Georgia with an article of manure, whose value can, in reality, only be properly appreciated by those alone who make the proper application.

These deposits of marl are discoverable immediately under the surface soil, and extend to an unknown depth. From some trials, made by the sinking of a few wells on, and near my lands, to the depth of twenty feet below the surface, there is but little appreciable difference in appearance of the marl.

The transitive lime-rock, of superior richness, always abounds in the neighborhood of these deposits. A few kilns of these rock have been put up and burned into the best quality of lime, either for building or the purposes of manuring. I have never been able to test the strength of these marls chemically, from the want of apparatus; neither do I know of its having been done by any chemist or geologist. But I am satisfied it is a far superior article to the marl of which Mr. Ruffin speaks in such high terms of respect, and which he found on the Santee and Cooper rivers, in South Carolina. I have been long acquainted with those specimens of marl, spoken of by Mr. Ruffin, on the Santee, and I am confident the marl in Houston is far superior; and, in addition to the superiority in strength, the application is much more easy: for the marl in Houston is found pulverized in nature, while much of the other is in the state of friable rock, which requires some labor to pound it before it is ready to be applied to the field.

You will now perceive that the same spirit of opposition to improvement in agriculture, which prevents planters from enhancing the value of their fields from one to five hundred per centum, while all the materials lie at the door, prevents them from taking your very useful paper, devoted to agriculture.

Yours, respectfully,

D. BRADWELL.

SELECTION OF SEED.

We are indebted to a much esteemed correspondent, for the following suggestions in reference to the selection of seed, which reached us just as we are going to press. We commend his views to the reader's attention, and beg leave to assure the writer that, so far from his letters ever becoming "*tedious*," the only complaint we have to make against him, together with several other zealous friends of our work, is, that we do not hear from them half as often as we desire.

"The perusal of Mr. Williams' prize essay, on the cultivation of Indian corn, afforded me much pleasure, and I hope some profit. He is wrong in one place: he throws away the best part of the seed. He says, 'The grains must then be taken from each end of the ear, and those of the middle used for seed.' The heaviest and best matured grains of corn on an ear, (and of course the best seed,) are those immediately at the large end, nearest the stalk. The correct plan, then, is to plant about half the grains on an ear of corn, beginning at the large end. The grains on the large end are sometimes disfigured by the pressure of the shuck while growing, which has probably led to the common practice of rejecting that part for seed; but the grains on the large end are the best seed, come up better and bolder when planted, and grow off faster, than from any other part of the ear. I have, (some years ago,) tried grains from every part of the ear, by planting them and watching the result. And the seed, from the large end of an ear of corn, will make roasting ears at least a week sooner than the grains from the small end.

The seed of the watermelon nearest the stem will produce ripe melons sooner than the seed taken from the blossom end. That I have tried. I have also observed, that the lowest grains of wheat, those nearest the stalk, on a head, are the fullest and best matured. An improvement might probably be made in seed wheat, by selecting those grains and sowing them. The suggestion is made for those who like to try such experiments. The same selection of seed might be tried on many other articles. No doubt other persons may have observed the same facts here stated: I mention them for the benefit of young farmers, who may begin in time to watch the most minute operations of nature; for they often lead to important practical and profitable results. For 'there are more things in earth, Horatio, than are dreamt of in your philosophy.'"

COTTON PREMIUMS.

Our readers will recollect that in a previous number we made some extracts from a letter of Col. A. McDonald, of Barbour county, Alabama; in which he referred to the importance of bestowing proper attention to the preparation of Cotton for market, and alluded to his own practice and experience upon this subject. As an evidence of his success, and to show to our readers how richly a little attention to this matter is rewarded, we take great pleasure in transferring to our columns the annexed paragraph and letter, which we clip from the "*Eufaula* (Ala.) *Shield*," and beg leave to commend it to the attention of every cotton planter.

COTTON PREMIUMS.—By the following letter, the reader will learn the disposition that has been made of the Premiums, offered by the Chamber of Commerce of Apalachicola, for the best Cottons sold in that market the past season—the farmer will also learn the great advantage of turning his attention to the *quality* rather than the *quantity*, when we inform him that Col. McDonald received 10½ cents for the very cotton upon which the premium of a fine silver Tea Set, has been awarded:

APALACHICOLA, April 27th, 1844.

COL. A. MCDONALD:

Dear Sir—We have the satisfaction of informing you that the Chamber of Commerce met on last evening, and awarded to your 20 bales, the Tea Set, as a premium for the best lot of 20 bales sold in this market this season. Yours was pronounced decidedly superior to any lot offered for any of the premiums: it was classed FINE, no other lot classed over *good fair*. Owing to some difficulty in making up the amount necessary to purchase the premiums, they have not yet been purchased; but the amount is now raised, and the Committee will send on in a short time, and make the purchases.

Captain Thornton's 50 bales took a premium, and Mr. Tyson's 10 bales. No lot offered for the 100 bale premium.

Yours truly,

MCKAY & HARTSHORN.

From the American Farmer.

A GOOD PLAN OF MAKING MANURE.

A writer in the Southern Planter recommends the following plan of making manure, of which we highly approve:

"Have a pit thirty or forty feet square and 2 or 3 feet deep, with a good bank around it.—In this pit, let the materials, viz: oak leaves, pine tags, earth, &c., be put in suitable layers; on which throw all the slop water, soap-suds, yard sweepings, as ley, contents of chambers, and in short every thing that can be conveniently got together. It may be at any convenient distance from the kitchen, so that the slop-water, soap-suds, &c., may be conducted to it by a trough. Be sure that no water gets into it in any other way. If at any time, it should become offensive, start your teams immediately and cover it over with *sand* or earth sufficient to prevent the escape of any effluvia."

We say we approve of this plan of making manure; but we think it might be improved by sowing plaster over each layer of the materials of which it is composed, and occasionally, say at intervals of two or three weeks, sowing it over the surface, by which means all unpleasant smells would be avoided, and the enriching gases saved to fatten the land. Any pit which may be made for the purpose, should be protected from the weather.

Selections, Extracts, &c

EXTRACTS FROM AN ESSAY ON THE INTERESTS AND DUTIES OF THE AMERICAN FARMER

Delivered before the Union Lyceum, of Hinds and Madison Counties, Mississippi, by Gen. PATRICK HENRY, of White Hall.

A farmer should not only be industrious and economical, but he should be emphatically an honest man. He has less excuse for being dishonest than any other man. At the same time, however, I do not mean to assert that any man can be excused for dishonesty, no matter what his calling or what his temptation. For if you admit anything to be an excuse, the whole temple of morality is overthrown at once—for I regard honesty as the chief corner stone; it is that without which the building cannot and ought not to stand a single moment. But still, I contend, the farmer should be the most honest of men, because he can be the most independent. With virtuous industry and frugal yet liberal economy, he can place himself, with the blessings of Heaven, beyond the pinchings of want. It has often struck me that the farmer should not struggle to be rich. There is something degrading in that feverish excitement to accumulate property—something which cankers all within and prevents the existence of one generous impulse, one high and lofty aspiration.—His end and aim should be an independent competence—at once removed from the temptations of wealth and temptations of poverty—for *both* have their *temptations*, and through to the general eye, the villain in silk and satin may not appear as forbidding as the same character in rags, yet to that eye which seeth in secret, and not as man sees, there is no difference. Pope has said, the saint in rags is twice a saint in lawn—and this is but another illustration of the fact that wealth *smothers up* character and hides its deformities, as well as sets forth its *beauties* in a more glaring light. But the farmer should repeat the prayer of Agur in spirit and truth, "Give me neither poverty nor riches." He should be comfortable and independent, but beyond this he should not wish to go—and by all means he should not make wealth, or its desire, absorb all his feelings and rob him of his usefulness as a man, and his peace and quiet, and permanent happiness. No! he should delight more in a good example, in knowing that his light shines abroad as an honest and independent farmer, than in being called a wealthy one. He should be fair in all his dealings with his fellow men, and never demand any thing, not the smallest cent, that was not justly due. He should square his conduct by the eternal principle of right, and be governed by the golden rule, Do unto others as you would that others should do unto you. If the world were governed by this rule in all its dealings, how much bickering and strife, and low cunning and deceit, would be banished from the land! How pleasant would be our abode on earth! It would be like the dew that descended on the mountains of Herman, like the precious ointment that ran down upon the beard, even Aaron's beard, that ran down upon the skirts of his garment, for it would cause the world to dwell together in unity and brotherly love. The farmer should be above doing a mean action—he should scorn with a sovereign contempt all over-reaching in trades, but he should be straight forward, unevasive and plain in dealing. He should not desire something for nothing, and he should not be governed by the rule to make as much as you can, no matter how you make it. No! No! He should not frown into utter *annihilation* the infamous thought, before it was even fully formed in his bosom. He should look upon the man who would practice upon such professions and principles with unmitigated contempt, and build a loftier name, though it be an humble one, and carve it high on the tallest pillar of renown—and that name, though its owner may move in the lowest walks of life, and lie upon the dead level with the general mass, and be despised by the dazzling sons of opulence and bloated ease, whose eyes stand out with fatness, is the name of an honest man—the brightest uninspired the sun ever shone upon in his meridian splendor, and better far and prouder than those which spring from carnage covered fields, and all the glory of titled ancestry or regal fame.

And here I might dilate with pleasure, upon the duties of the farmer in the settlement of accounts and collection of debts. It has ever appeared to me, that too much strictness—or in other words, too exacting a spirit was beneath the real dignity of the profession of farming, which is liberal and noble in its very nature. A spirit of liberality should be encouraged,—it should be taught to our children; where they do not naturally possess it. It should ever be remembered, that all men do not think alike, and that slight differences will occur, in matters of opinion, and especially in matters of account. What I wish to see inculcated is, that generous spirit which will overlook trifles, and yield much for the sake of the peace of the neighborhood. I do not mean that they should yield great rights or privileges—by no means—but I mean in the adjustment of small neighborhood matters, that it is better to lose a trifle, than to contend for it—it is better to yield a few dollars, than to lose a neighbor—it is better to settle amicably among yourselves, even at a small sacrifice, than to adhere pertinaciously to your rights and seek redress in court—where the accruing costs will be greater than the original demand. It is better to yield it for the sake of peace—for the sake of your own dear interests too.—It used to be a common remark in Mississippi: that I will have what you owe me or blood. This lawless spirit has given way to the sound dictates of common sense. Thank God! those days have past, and a spirit of sound and liberal morality, in opposition to the all-grasping spirit of avarice, has been breathed upon the land, and peaceful quiet, and law abiding people, are now the possessors of the soil. The farmer in particular, has the greatest stake in the preservation of order, and in the mild reign of the law, and he should enter his protest against all neighborhood strife, and show by his conduct that he places a just estimate upon these invaluable blessings. I know it is regarded by some that so a man is honest, it matters little how close he settles. This is not my opinion. No man should be too exacting. He does not feel so well—he does not so completely receive the approbation of his conscience, by being rigid and griping in his dealings, as does he when his conduct has been characterized by a generous and liberal spirit—a spirit that is above contending about trifles, and that would throw them rather to the moles and the bats.

In this connection, I cannot urge too strongly the necessity of a proper understanding in all cases where there are dealings between man and man. If this were more frequently attended to, our court houses would not be so frequently crowded with farmers and their witnesses, to the destruction of the peace of neighborhoods; and to the pecuniary disadvantage of both parties.

Look around you at the affluence which blesses your professional men, your lawyers, and clerks, and magistrates and sheriffs. Did they acquire their fortunes by the cultivation of the soil—not at all. In a great measure the misunderstandings of the people have caused them to grow rich. Are those gentlemen to blame? —no! no! If the people will throw their honest and hard earnings away, they had as well get them as any body else. I have heard of a debt of $14, costing, by the animosity of the parties, $3,000; when the arbitration of neighbors, or the liberality of the parties themselves might have settled it out of court.

Another thing of vast importance, in the settlement of difficulties is, confidence in the honesty of your adversary—confidence begets confidence, just as naturally as distrust begets distrust. A suspicious and cross-grained man will mar the peace of families, and distrust the repose of neighborhoods, and sow the seeds of discord broad-cast through the earth. Such a man should be met with an open, frank and confiding spirit—and it will have the tendency to produce the like spirit in his own bosom. By such a course the whole man may be changed.

I have heard it gravely argued, that you should do as you believe your neighbor would do under similar circumstances. Thus you are to begin by attributing villainy to him, and end by being a villain yourself How different was the immortal doctrine of Christ! On how much more noble feelings was his golden rule based. The selfishness of the human heart was duly considered, and that very selfishness was made the test of honesty. He went into the human heart, and inquired what would your selfishness and self-love dictate that he should do to you—that is the rule of your conduct then to him.

The farmer too should remember the poor in mercy. He should be mindful of their interests on whom the desolation of poverty has come with a blight and a mildew. He should not grind the face of the poor, but should raise the bowed and broken down in spirit. He should remember the kind and gentle conduct of Boaz to Ruth, and leave the subsistence to the gleaners. Charity is like the soft dews of Heaven. It is twice blessed—it blesses him that gives. It is the high prerogative of the generous and liberal farmer to ascend to the throne of Heaven in deeds of benevolence—and to make his goodness and his usefulness as expansive as his existence.

But he should not only be honest and industrious, and economical and liberal—he should be a married man. This is absolutely necessary for his happiness. He may live without the smile of partial beauty won, and may be respectable—it is possible that he may practice all the virtues of an honest farmer, but when he turns to his home, how his heart sickens within him, when he reflects that that home is not consecrated by the presence of one whose thoughts, feelings and taste, are harmonious to his own, and who is ever ready to welcome him with a smile after the labors of the day. And then, after he reaches that home, follow him if you please into his desolate dwelling, unenlivened by the caresses of his family, and unadjusted by the plastic hand of lovely woman—all is disorder and confusion—confusion worse confounded. His home is a dreary and unprofitable waste, a barren garden where no verdure quickens, a wretched excuse, where all the freshness and purity and warmth of affection, languishes and dies for the want of congenial objects to call it forth and give it life and animation. But let that old bachelor marry, and the whole scene is reversed, as if by an enchantress' wand. Aladin's lamp had not more power in transforming scenes and giving to them beauty and brilliancy, than does the presence of an affectionate and intelligent lady transform the dullness and desolation of a bachelor's domicil into the fascinations and enchantments of matrimony. Order seems to spring up at her approach, and economy reigns throughout the household as a presiding genius. The whole scene is reversed—and a cultivated garden, a parterre of unrivalled flowers, wafting their sweetness through the remotest chamber—a well-ordered and well-set table of the choicest viands are presented in the stead of barrenness and scantiness, and slovenliness, at which the heart mourns in sackcloth and ashes at their bare enumeration. But who can recount the unnumbered blessings that cluster round that fond word home, when blessed with woman's presence? It would be an easier task to count the stars that deck the firmament at the midnight hour—or to number the sands upon the shores of the sea. It is sufficient to assert that no farm can be properly conducted, without the aid and advice of a wife. They are our best and safest counsellors at all times—they are the truest economists, and I attribute one half the distress of the land to a disregard of the counsels of our wives and mothers. Who ever heard of a wife recommending her husband to go in debt, or to speculate? No, no! their advice was constantly urged to the contrary, and

the men as constantly disregarded it. Judgment had fled to brutish beasts and men had lost their reason. They slighted the still small voice of reason, and took the mild bit of restraint in their mouths and ran lawless through the wild field of speculation.—And the sad result is, the overthrow of many estates and the reduction to poverty of thousands who were born to affluence. The first return to good sense that was witnessed in Mississippi was the passage of a law by the Legislature, giving certain rights to married women—rights which would protect them and their children from the world's cold charity, and all the ills which poverty brings in its train. To the farmers I most confidently say, marry, and listen more to the counsels of your wives. Let their bosoms be the repository of your secret circumstances, and they will not run you in debt. If they have ever been extravagant, it is where they thought their husbands could afford it, and their husbands through mistaken pride, failed to expose their real situation to them. They are our best friends, and friends whose counsel has never betrayed or led to ruin. Hearken then to the voice of those whose interest is identical with your own, and who are not so easily led astray by the visionary schemes of the mere speculator as yourselves.

But as invaluable as the ladies are as counsellors, their merits rise to perfect admiration when contemplated as nurses round the couch of sickness. There they shine with peculiar splendor and unrivalled excellence. When the hand that adjusts the pillow and presses the throbbing temple, and the eye that looks into yours with an interest that cannot be contemplated, and the voice that melts into tenderness as its tones soothe the anguish of pain, is that of affection and love, woman becomes an angel on earth. Oh woman! in our hours of ease, uncertain, coy and hard to please, and variable as the shade by the light quivering aspen made, when pain and sorrow wring the brow, a ministering angel thou.

The farmer should set good examples to his children also. He should inculcate truth as a jewel of rare value, and should be devoted to their education. By industry and economy, he will unquestionably be able to bestow good educations on all of them. It is too frequently the case that farmers educate a portion of their sons for the professions, and leave the mental field of their farming sons uncultivated. This is wrong in every point of view. It is yielding the point at once that those professions are more honorable than the calling of the farmer, which I deny. He stands in the foremost rank, and should be educated as high as the best. I might go further, and say that the profession of farming is the most honorable that man could follow, but I should regard such a speech as anti-republican in its character. I am content in asserting that none is more honorable, and that as a class none are more respectable. If there are exceptions, the fault is with themselves and not in the calling. If we are underlings, the fault is in ourselves and not in our stars. We, for I speak of farmers, should take that rank which nature intended we should occupy. We should remember that the father of his country was a farmer, and that without derogation from other professions, it will be admitted on all hands that he stands on the page of history without an equal —without a model—the pride of every land, the glory of every age.

When our republican institutions are remembered, and the fact that all offices are open to all men, and that "worth makes the man and want of it the fellow," it is astonishing that more attention is not paid to the culture of the mind of the most numerous class of citizens. Farmers should not only have good educations, but they should be early taught a free and easy mode of expressing their sentiments in public. They should not entrust the keeping of the archives of our liberty and its sacred vestal flame to the learned professions alone, but they should become candidates for their possession and rivals in the race of eminence. They should aspire to office more frequently than they do, and become familiar with the mode of conducting public business. They are the bone and the sinew of the land, their country's pride and their country's boast—and, if properly enlightened, should have a more correct idea of their public wants than any other class. They would be wiser and better voters, and we would not so frequently see our public councils darkened by the promotion of unworthy men to office. Our high places would not be so frequently filled by the mere demagogue, whose trade or whose livelihood is politics—but they would be filled with sober, talented, business men, "who know their rights, and knowing dare maintain." The farmer, then, should begin a liberal system of improvement in the education of his children. Every motive that can influence the human heart, operates upon his with unspent force and vigor. The genius of liberty appeals in the moving pathos of patriotism, by the holy devotion of country, in behalf of education. It is the foundation of our country's greatness and the hope and assurance of its independence and perpetuity.

Farmers should read more—not merely books, but newspapers, political, agricultural, literary, and religious. Every family should take a newspaper. It makes children fond of reading, and gives them a knowledge of the affairs of the world that it would take years to acquire in any other mode. And at this day, the press can afford intelligence at so cheap a rate that every family can bear the price of at least one newspaper. If the plan were adopted of cutting off the use of some useless habit, how many papers would it introduce into the neighborhood? For instance, stop the expensive and filthy practice of chewing tobacco or smoking, or drinking, or any other custom which is so useless or unnecessary, and devote the money to the purchase of newspapers—how much better it would be. How many farmers' wives and children would rejoice at the exchange, no man can tell. It would be a most happy result, and one that would redound to the immortal honor of him who would start it—and after it has been commenced, a good way is to exchange papers with your neighbor—by that means you double your information and do not increase your expense. I hope a suggestion so fraught with interest and enjoyment will not be neglected, but put into immediate requisition.

From the American Farmer.

WET LANDS.

We have frequently recommended the draining of all naturally wet lands, and we will here repeat our advice, as it is impossible to realize good crops from soils which remain in a state of super-saturation for a considerable time after every fall of rain. Many, we are aware, are deterred from subjecting their lands to this operation through fear of the expense; but this consideration should not be permitted to prevail, as the cost of draining, if properly executed, would not prove the scare-crow which many apprehend, as a large portion of the labor could be performed with the plow, the shovel being at the most required to throw out the loose earth which could not be extricated by the former implement, until the drain should get to be a foot deep.

With regard to the kind of drains, we have no hesitation in saying that we should prefer *covered ones*, which could be formed with very little labor. Suppose the drain should be cut 18 inches or two feet deep, and the same width, all that would be necessary to make one that would last a life time, would be, to lay on either side of the drain chesnut, cedar or locust poles, 4 inches in diameter, the ends made to fit plum up to the ends, then to lay blocks of the same materials, close together across them; on these let pine or cedar twigs, or long unbroken straw, be placed, to prevent the earth from falling through the interstices and choking up the drain; then fill up the drain, taking care to preserve at least a foot between the surface and filling in, so that the plow would not displace the poles in after culture. Indeed, where neither chesnut, locust nor cedar poles could be obtained, those of pine would answer, and last for twenty years.

In England, Scotland and Ireland, where draining has been longest followed, and best understood, the most decided advantages have been derived from the practice. There lands, of comparatively little value, have been, by the operation of draining alone, rendered not only available for every kind of crop, but eminently productive; and soils which had been looked upon as among the most heavy, tenacious clays, have been converted into pliable loams.

With regard to the distance at which the drains must be cut apart, that must depend upon the quantity of water to be passed off. In most cases, from 18 to 22 feet has been found a sufficient and safe distance. The drains across the field should be made to empty into others of bolder dimensions, at the terminating points, which should be of sufficient capacity to receive all the water which may be discharged into them. Care should be observed too, to preserve a proper level, so that the water may pass freely throughout every part of the drain.

We have no doubt that, by such drainage of heavy clays, given to excessive moisture, that at least fifty per cent. of the labor of tillage might be economised, twenty-five per cent. of productive capacity be added to them, and lands which are only now fit for grass culture, and not peculiarly adapted to that, might be transformed into soils fitted for the growth of every description of vegetables, from the turnip to the corn plant.

With regard to the quantity of such ditching, which can be done in a day, we have no hesitation in advancing the opinion, that the materials on the ground and deposited in place, that four men, a good team, a plow and three shovels, could perfect a mile in length in a day, *provided they were superintended by their employer*, and we would not advise any one to undertake such labor, unless he gave to the operation his personal attention during the whole time. His presence, judgment and direction, would be more than equivalent to the work of two laborers; besides the assurance he would have that the work would be well and effectually done. There may be, and doubtless are, hands that do not require watching, though we are forced to confess that we have never yet seen them; for, so far as our experience has gone, and we have not had a little, the chief aim in most of them is more directed to the killing of time, than in the employment of that time in good old-fashioned honest occupation. This may be considered by some as a harsh judgment, but if we had not so pronounced it, we should have been lacking in that candor and frankness which has been our rule through life.

From the New York Central Farmer.

TAKE CARE,

Should be the watchword of every farmer. There is no time to dispense with it, from the first day of January to the last day of December. And yet some would judge, from appearances about the premises of some farmers, that they hardly knew that those two words belong to the English language. To take care of anything, whether it be buildings, fences, crops or animals, seems never to have entered their minds as a thing of any importance. And even among those who would probably like to be called pretty good farmers, there is too often a manifest disinclination to *take care*. But, although they are two small words, and quickly told, the good or ill success of every farmer, depends in a great measure upon the observance or neglect of them. No great number of acres, nor any amount of hard labor, will enable any man to dispense with them. If you would even raise a flock of chickens, you must *take care* of them. But little time is required to raise a hundred, provided you have the necessary conveniences for taking care of them.

If you wish to raise a litter of fine, thrifty pigs, *take care* of them. While they run with their mother, she must have *enough* to eat, of some-

thing: when you take them off, they must be fed not once or twice a day only, but five times at least—not twice as much as they can eat at a time, but just as much as they can eat, and no more.

If it is your intention to raise two or three, or half a dozen calves, you may as well have good ones as bad ones—only *take care* of them. In the first place, breed from the best stock you have, or can produce, and then feed regularly with a sufficient quantity of *some thing*, not so much matter what: they will readily learn to eat almost any thing—sour milk, or whey, with a trifle of meal, answers a good purpose, only let it be regular as to time and quantity. "This tampering and stuffing and overfeeding," as Mr. Bement says, is not the thing—it is not necessary. *Good stock* can be raised without it, even from our native soil. But a little *care*, especially the first summer and first winter, they must have.

If you wish to have your fodder hold out well, *take care* of it. Have every animal in the stable if possible, not only nights, but cold stormy and windy days—feed little at a time and often, not only night and morning, but through the day.

If you wish to increase your quantity of manure, *take care* of it. Keep your cattle close in the yard, and put up eave-troughs to carry off the water, so that there may be as little wash as possible. If there is a drain at one side of your yard where all the moisture runs off, try and prevent it. A speaker in a late agricultural address says, "you may as well have a *hole in your pocket*, as a drain from your barn yard." If you would raise good crops, *take care* of them. They must be fed as well as your cattle; or they will not grow. Plow thoroughly, to cut and cover won't do, neither will you have a great crop of grain, and a *very* great crop of weeds at the same time. Have an eye to your fences; if a board gets loose, or a rail is ready to tumble off, try to find it out before your cattle do.

If you have a family of children growing up, to take your place in this busy scene of things, when your race is run—you would probably be glad to have them become wiser and better men and women, than their father and mother were before them—then *take care* of them. Feed and clothe their bodies decently, but don't forget to feed their minds. Give them all the opportunities of a good and substantial education within your power. And whether they be male or female, and whether you expect to leave them rich or poor, learn them to *take care*.

From the American Agriculturist.

MANURING STRAWBERRIES.

There appears an undue fear of manuring strawberries. I have read somewhere that all plants that throw out suckers or runners rapidly deteriorate the soil, and that a power of escape to new ground is given by the runners. If this is correct, it is a reason for the good results I have always seen of manure. How rarely, except where strawberries are grown for profit, do we see room enough given. Beds of strawberries are objectionable for this reason, and it is this cause rather than manure that leaves are more abundant than fruit. I have tried and proved this. Where strawberries are grown for profit, (that is, grown at all in the true sense,) they should be planted in rows—the large sorts not less than 30 inches in the row, and 15 inches from plant to plant, and no runners suffered to remain. By these means, with deep trenching and early planting, any sort worth cultivating may be grown large and abundantly.

Obituary.

From the Albany Cultivator.

DEATH OF WILLIS GAYLORD.

A bright light has been extinguished in the death of our associate and friend, Willis Gaylord. He expired at his residence, Limerock Farm, Onondaga county, on the 27th of March, in the 51st year of his age. An aged mother deplores the loss of a most devoted son, over whose fragile form she had watched with all a mother's tender care for more than fifty years—a brother and sister weep for one who had ever manifested for them the most heartfelt affection—and his friends, and none more than ourselves, mourn the loss of one, beloved alike for his genius, his faithfulness, and the happy temper of his mind; while the American farmer has to regret the sudden departure of one who has labored zealously and successfully for years to promote his interest, to enlighten his mind, and to elevate his calling to that dignity and respect to which it is so justly entitled. His death was sudden, and to his family, as well as to us, most unexpected. He was taken with a bilious affection of the stomach on the night of the 25th. The next morning a physician was called in, and remedies were administered, which it was thought would afford relief. No alarm was felt, as no immediate danger was apprehended, till early on the morning of the 27th, when it was discovered that his life was rapidly drawing to its close. At 9 o'clock, thirty-three hours after the commencement of the attack, he sank gradually and gently into the arms of death without a groan or a struggle. He had been for more than thirty years a worthy member of the Presbyterian Church, and the hopes and consolations of the gospel had enabled him to endure, not only without a murmur, but with a buoyant and cheerful spirit, an amount of bodily suffering which falls to the lot of but few.

Mr. Gaylord was born in Bristol, (Conn.) in 1792, and removed with his father's family to Otisco, in this State, in 1801. This town was then almost an unbroken wilderness, but three families having preceded that of Mr. Gaylord's father. Young as he was, the deep, dark and majestic forests, as he entered them, at the beginning of summer, made an impression upon his mind, and excited a love for trees, which was never effaced. He always spoke of them with enthusiasm. In a letter, written but a few weeks before his death, he says—"When we entered these forests, the heavy foliage wore its freshest green, and the elm, the maple, and the linden, were successively laden with flowers; and never shall I forget the rich, the indescribable perfume which filled the air, as tree after tree was cut down, and day after day passed away before the blossoms had ceased to exhale their odors from their withered cups." Deprived as he was, by this removal, at the age of 9 years, of the advantages of even the District Schools of his native State, he was soon after visited with an affliction which prevented his reaping the benefits to be derived from the establishment of the similar institutions which are sure to rise up in all new countries, peopled by emigrants from New England. At the early age of 12 years, he was attacked with a violent rheumatic affection, which resulted in a curvature of the spine, and unfitted him, in all after-life, for any active or laborious pursuit. His innate love of knowledge, however, was such that no bodily infirmity or ordinary obstacle was permitted to dampen his ardor for its acquirement. Being unable to attend school, he studied such school-books as were to be procured at that early day, carefully noting such parts as he could not alone surmount, till he could obtain the assistance of some one who was able to solve his difficulties. He not only read with avidity, but *studied* all the books which came within his reach. He was remarkably fond of rural scenery, and when the weather would permit, it was his delight to sit for hours under the shade of trees, and cheered by the singing of the birds, pursue his studies with pencil and paper in hand to note the current of his thoughts.—While thus engaged in the pursuit of knowledge, and in the enjoyment of such a degree of health as permitted him occasionally to engage in the lighter labors of the farm, he met with an accident, slight indeed at first, but which entailed upon him a vast amount of suffering, and rendered him almost as helpless as a child to the day of his death. It was occasioned by a fall, from which, at the time, he noticed only a slight bruise on the left arm. It afterwards swelled, and became a running sore, causing the decay of the bone, and rendering his arm forever after entirely useless. This affection of the arm continued for about a dozen years, and when it healed an abscess occurred in one of his sides, which continued, with occasional alleviations, till his death. Notwithstanding the pain he was thus obliged to endure for a long series of years, which was sometimes excessive, he was ever cheerful and happy; and even under the most acute suffering, was never known to utter a word of complaint.

At the appropriate season, if his health permitted, he resorted much to the woods and fields. A favorite retreat was the shore of one of those beautiful lakes which adorn the western section of our State; and there, enjoying the charming view and inhaling the refreshing breeze, his mind was at once soothed and strengthened by a contemplation of the varied phenomena of nature. His was that happy constitution of mind which finds

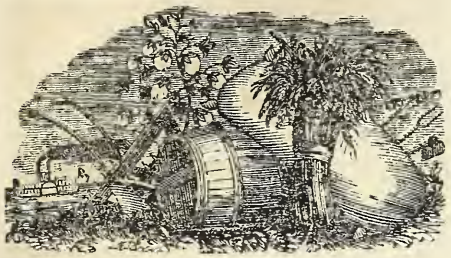
> "Sermons in stones, tongues in trees,
> Books in the running brooks,
> And good in every thing."

"Disqualified by these calamities from labor or active physical habits," in the language of one who knew him well, "he devoted his mind to study; and although suffering under severe bodily affliction, deprived of the ordinary facilities for obtaining information, without teachers, and by the aid only of such books as he was enabled at that early day to collect, he became a ripe and sound scholar, and eventually one of the most able and powerful writers of our times. For more than twenty years he had been a regular contributor to many of the American Quarterly and Scientific Journals, and in several instances to some of the most popular Magazines in Europe. His contributions to the newspaper press of this country, on almost every variety of topic, literary, religious, scientific, miscellaneous, and occasionally poetry, have been numerous and of the highest order of excellence. As a writer on all of these varied subjects, whether we regard the beauty of his style, the chasteness of his diction, or the invariable accuracy of his facts, it would be difficult to find his superior.

"The versatility of his talents, the rapidity with which he wrote, and the great number of his productions, have excited alike the admiration and astonishment of his friends.

"But the most valuable part of his writings, and for which he will be longest remembered, relate to the passion of his latter years—practical and scientific agriculture. In these departments he was thoroughly versed, as his contributions, commencing in 1833, to the old Genesee Farmer and the Albany Cultivator, will abundantly attest. The services he has rendered to the farming interest of the country have been immense, and form a legacy which will endure to a late generation. He was eminently practical and judicious in all his views and recommendations, and possessed a happy tact in communicating his impressions to others. To the readers of the Cultivator, and to the agricultural community, his loss will be irreparable.

"Isolated and excluded as he was by physical infirmity and location, from a general intercourse with his fellow citizens, there are consequently but few who can justly appreciate his many social qualities. Thoroughly informed on almost every subject of general or individual interest, he was always ready, as it was his delight, to impart to others who sought his society, the rich treasures of his well-stored mind. Those few and favored friends, will long and fondly cherish his memory. As a man, his philanthropy knew no bounds. He studied and labored emphatically for the benefit of mankind. As a friend, he was true and faithful; as a son and a brother, kind and affectionate. When a man of such gifted powers and universal acquirements, in the full maturity of his intellect, and in the midst of his usefulness, is cut down suddenly and removed from among us, we may in truth mourn a public bereavement."



WEDNESDAY, MAY 15, 1844.

PATENT OFFICE REPORT.—We make our acknowledgements of the Hon. H. L. ELSWORTH, Commissioner of Patents, and the Hon. A. H. STEPHENS, for copies of the Annual Report made by the former to the present Congress. Like his former valuable report, it contains much matter of lively interest to the Agriculturist; from which we shall, in our future numbers, make such extracts as we deem of interest to our readers.

From the American Farmer.

LARGE YIELD OF CORN.

The Farmer's Visiter gives the following account of a large yield of corn, grown in the District of Columbia; which shows that even an indifferent soil may be made by manure to send forth abundance of the fruits of the earth. The quantity of manure used was to be sure heavy, but when the difference in the price of the labor of cultivating but 4 acres, instead of twenty, is considered, the account of cost will be pretty nearly balanced, without taking into consideration the difference in the value of the land after the crop was grown :

"The capacity of the soil in and about the city of Washington, is demonstrated by an experiment of Mr. Hickey, a Clerk in the office of the Secretary of the United States Senate, who resides about two miles from the Capitol, near the turnpike road leading to Bladensburg. Mr. H. has a family of slaves by whom, overlooked by an Irishman, his labor is performed. The last year, instead of pursuing the old practice, and going over some twenty acres to be planted in Indian corn, producing at the rate of two to three barrels to the acre, he prepared and planted only four acres. This land he manured at the rate of about 120 small horse cart loads to the acre, plowing the ground more than once until it was well pulverized. The ground was furrowed in rows at four feet distance, and the hills in the rows were suffered to stand two feet apart with three stalks in a hill. A practical farmer of the neighborhood is of opinion that the crop would have been larger if there had been two instead of three blades in a hill The corn in Maryland is of much higher and larger growth than the New England corn, and requires a less number of blades and a greater distance to the hills. In the lighter lands, they have only a single blade to the hill, and the hills four feet distant—in the better lands two blades at the same distance. Mr. Hickey's field was three blades at only two feet one way and four feet the other. Had not the season been peculiarly favorable for corn, Mr. H. now thinks his crop would have been a failure, from the too great number and contiguity of the blades. But his crop turned out to be an uncommon one—22½ barrels of shelled corn, (five bushels to the barrel,) on one acre, and 20 barrels to the acre on the three other acres—making his whole crop 412½ bushels.

The largest producing acre was upon a young apple orchard, which had but now commenced bearing, and produced besides the corn with the growth of the trees, about ten bushels of choice apples. It may be readily perceived that the four acres of ground is now in a condition to produce double, and perhaps treble crops, without further manuring from three to five years. How great must be the gain of capital and labor expended on such improved cultivation."

☞It is in Agriculture, as in every part of creation, a wise and paternal Providence has inseparably connected our duty with our happiness.

☞A correspondent of the Prairie Farmer, says a lady of his acquaintance colors wool and woolen goods, blue, with *purslane*, a common garden weed—that the lady assured him it was equal in every respect to the best indigo blue.

ASPARAGUS.—For manure, guano mixed with sea-salt, and applied in a liquid form, has proved most beneficial.

☞The eye of a master will do more work than both his hands. Not to oversee workmen, is to leave them your purse open.—*Franklin.*

VALUABLE SALVE.—Take three carrots and grate them; place in a vessel and cover with lard, without salt. Boil thoroughly, strain, and add sufficient beeswax to make a paste. This is a most invaluable ointment or salve, for cuts, burns, scalds, or wounds of any kind.

BROOM CORN.—The Connecticut Farmer's Gazette says: Immense quantities of broom corn are raised on the Connecticut river, in Massachusetts. It yields about 1000 lbs. of brush, and 60 to 70 bushels of seed to the acre. The brush sells for 5, and sometimes as high as 12 cents the pound, and the seed at 33 cents per bushel. Its cultivation is like that of the Indian corn.

MANURE FOR MELONS.—The London Gardener's Chronicle says: It is contended that hen-dung is equal to pigeon-dung, in producing a large quantity and fine quality of melons.

☞When we take people merely as they are, we make them worse; when we treat them as if they were what they should be, we improve them as far as they can be improved.—*Goethe.*

HAPPINESS.—An eminent modern writer beautifully says:

"The foundation of domestic happiness is faith in the virtue of woman: the foundation of political happiness, a confidence in the integrity of man: the foundation of all happiness, whatsoever, temporal and eternal—reliance on the goodness of God."

From the New Genesee Farmer

ORLEANS COUNTY PREMIUM CROP OF INDIAN CORN.

Asa Williams, Jr., of the town of Barre, in the county of Orleans, having received at the last annual fair of the Orleans County Agricultural Society, the first premium awarded for the best acre of Indian corn, makes the following statement of the manner of cultivating the same, soil, seed, &c.:

The soil was gravelly loam, containing a good portion of black vegetable mould. I planted in corn stubble: it was first plowed in the spring of 1842, having laid in pasture ever since it was cleared, some twenty years since. It was a swale, and had been ditched and drained the year before it was plowed. In the spring of 1842, I spread on about twenty-five loads to the acre, of well rotted barn-yard manure. In the spring of 1843, I put on, and plowed under, about the same quantity of the same kind of manure; plowed it twice—one each way, about the 6th of May: about the 10th, planted on the furrows, in rows about two feet apart, and hills about one foot apart in the row—three kernels in each hill. It was hoed three times, making as little hill as possible, and no cultivator or drag was used on it. It was cut up by the ground, about the 15th of September, and put up in shocks or stocks on the ground. The committee of the Agricultural Society came to the field and measured off one acre: they counted the rows in the acre, and then selected one row, which they deemed to be an average row. They then appointed a man to husk and shell it: when that was done, the product was measured, and the crop on the acre from the product of this row, was estimated at one hundred and fifty-seven bushels and thirty quarts, by measure; and by weight, at one hundred and fifty-four bushels and twenty-one pounds.

I would add, that I personally superintended the harvesting of the whole acre measured, and have no doubt but it would average the product of the row that was measured. The seed used in planting, was what is called the white red-blaze—eight rowed.

ASA WILLIAMS, Jr.

Barre, April 10, 1844.

REMARKS.—The foregoing statement was furnished at our request, in order that the county of Orleans might have the credit of having produced one of the largest crops of Indian corn on record in the annals of agriculture in the empire state. It is a great pity that the whole crop was not accurately measured and attended to, so that it would have obtained the premium of the State Agricultural Society, and so that those who read the account would not feel inclined to doubt its accuracy. From our own knowledge of the parties concerned, we have full confidence in their integrity; but at the same time, we are aware that the statement shows such an extraordinary product, that many farmers will think there is some mistake, or deception about it. We know, however, that Orleans County contains some of the best corn land and best farmers in the State; and as other counties claim to have produced crops equal to this, we see no good reason why, with a favorable season, and improved mode of culture, we may not advance a *leetle* beyond all that has been done before.—We have always contended that *perfection* has not yet been reached, in the culture of this, and other crops.—ED.

From the New Genesee Farmer.

HOW MY FRIEND COOK RAISES WHEAT.

Few farmers in our county raise as good crops of wheat, and none better, than Mr. Ira Cook, of Byron. His method is a good one, and can be adopted by any farmer in the wheat region. It also proves that the same crop may be grown upon the same land for any number of years, and at the same time have the land constantly improving in value. The whole secret is, deep plowing, gypsum and clover. He stocks his wheat ground in the spring with clover, and sows on plaster. The next spring the clover is plastered again. When up, rank and heavy, he goes on with a strong team, and turns under the clover, and sows on his wheat. He says he has turned under clover that would yield at least two tons of hay to the acre: and he further says that from his own knowledge the land will bear a heavy crop of wheat every other year, and still improve in fertility. Wheat can be raised in this way at much less expense than in any other, as summer fallowing can be dispensed with entirely.

Mr. Cook also pays great attention to his garden, and has his privy so constructed as to be able to save all the night soil, or contents of the vault. He keeps a pile of sand handy, and occasionally throws in sufficient to keep the vault dry. This is every year applied to his garden—and a most excellent application it is. I think muck, if at hand, would be better than sand, unless the sand was quite loamy. Any kind of light earth that is fit for a garden, will answer the purpose, and should be used; for

truly manure is the farmer's mine. He is about doing another very wise thing: and that is, to build a cistern in his garden, into which all the wash of his kitchen will be conducted; and this he intends to apply upon his garden in a liquid state. And thus he has a very valuable garden. However, every farmer can do as much as Mr. Cook has done; for it is within the means of every one to save all their manure and apply it to their crops in a safe and judicious manner. But as I hope some day to visit Mr. Cook, I shall say no more about him now.

Speaking of manure, reminds me of a little experiment I tried the other day; and it may be of service to others to know it: I noticed a manure pile near one of the stable-doors to be in a high state of fermentation, and sending forth a dense vapor. The pungency of the odor clearly showed that a large quantity of ammonial gas was escaping. I had a quantity of ground plaster scattered over the heap, sufficient to make it quite white, and in a very short time the vapor ceased to appear. The plaster was changed in color perceptibly. This only shows that the theory of plaster's absorbing ammonical gas is true, and that the practice that has obtained to some extent of sowing plaster on compost and manure heaps, and upon dry meadows and pastures, as well as strewing it liberally in stables, is a very excellent one, as it fixes the ammonia which is the very essence of manure. The whole becomes a new compound, and easily dissolved in water, thereby rendering it more nutritious to the growing plant.

Deep plowing is a great thing to help keep up the good condition of land, and to insure good crops. I don't mean four, five, or six inches, when I say deep plowing. I call it deep plowing, when the plow goes in beam deep. My neighbor Corbey has some excellent notions on that subject. He used to live in Ontario county, some thirty years since, and was lately back there on a visit. He told his friends they did not raise such crops as they used to when he was among them, and pointed to the stubble as a proof. In those days seventy bushels of corn to the acre was no uncommon crop. He told them that it was not so much the want of fertility in the soil, as it was the want of good judgment in its management. When he lived there, they used to plow their land with two yoke of oxen and a horse; now they used a span of light horses, and they ought not to wonder if they had light crops. If we skim over and skin the soil, the soil will skin us, as a great many farmers now find to their sorrow. P.

From the Albany Cultivator.

TO DESTROY NUT GRASS, &c.

Messrs. Editors—I see that a subscriber asks for information how to kill nut grass. If he means by it, that which has proved so great a curse on the coast of Louisiana, I would suggest as an experiment that a small plot of ground, say a square perch, be taken, and sow on it at the rate of 40 or 50 bushels of salt to the acre, and mark its effect, if it has that desired. I think that thousands of acres on both sides of the Mississippi would be reclaimed and be made even more fertile than at present. This much I can venture to assert: that it will not only kill that or any other grass that appears for some distance below the surface of the ground, but whether it will extend its salutary effects to the bulb or not, must be proved by the experiment. It has this advantage: that it can be tried at but little expense.

Acclimating Cattle.—Whilst I am scribbling, I might suggest to a Southerner, who requests information, in last year's vol., about acclimating the improved breeds of cattle, that my opinion of the great difficulty that occurs, does not arise so much from the change of food or climate, as the state of irritation and fever that they are kept in by the incessant attacks of the horse flies and mosquitoes, so that they can get no rest by day or night. Now I think that may be obviated by sponging them in a steep of the leaves of the black walnut, tomato vine, or many other strong and pungent leaves, or a solution of soot might answer, as any man in the South knows how repugnant the smell of soot is to the insect tribe, particularly to the mosquito. Mago.

From the New Genesee Farmer.

GOOD BUTTER.

The season is now at hand for making butter; and I wish every farmer's wife and daughter would try to make a better article than was ever seen before. It is just as easy to make a nice, good article, as to make a poor one; and it is certainly vastly more for the comfort of the consumer. Take pains—churn your cream before it gets bitter, and skim your milk before the cream gets any bad taste; work it well, but not too much; get the milk out and the salt in with as little delay as possible; use only the finest and purest rock salt, or the solar salt of our own springs that has been ground. A great deal of good butter is spoiled by the salt; and many a good butter-maker has been blamed when it was no fault of hers. When butter is put into firkins, it should be pounded in with a layer of salt on the lower head, and an inch of strong pure brine on top of the butter; and the firkins should be made of thoroughly seasoned wood—white ash, oak, beech or hemlock, but it must be seasoned. A great loss is sustained every year by putting butter in unseasoned packages. To make good butter, it wants care, cleanliness, and good salt; and plenty of salt at all times for the cows. Let us all have good butter this year. P.

From the Massachusetts Ploughman.

TIME OF SPREADING MANURES ON GRASS LAND.

A correspondent asks our opinion as to the most proper time for spreading manures over grass grounds?

We are decidedly in favor of spreading in November in preference to any time whatever in the spring season. We commonly lose a large part of our manures when we spread them at any time on land that has long lain in grass. But as there are many natural meadows that cannot be easily plowed, we dress them by an application on the surface.

Many farmers near Boston spread manures on their grass fields as late as May; and if the month holds rather dry, they find but little benefit from it. Within our own observation, there are instances of such spreading which has positively proved detrimental to the harvest. In a wet season, it will operate better; but almost any kind of application in the spring is apt to come in the way of the scythe and of the rake.

The best time is November, when the application is less liable to dry up or evaporate.—Much loam or other matter should always be mixed with manure that is to be spread on the surface of mowing lands.

From the Connecticut Farmer's Gazette.

LIMA BEANS.

To have a good vegetable garden, should be the aim of every man, and woman too, who has the occupancy of a *patch* large enough to make one. Many people seem to think that vegetables are vegetables, and it matters not what is the quality, if in quantity they do not fall short. We would remind such that some good things are a great deal better than some other good things—and among the best of garden vegetables, we class the Lima Bean. It is a tender plant, and needs careful culture. Plant from the middle to the last of May; having the soil made rich and deep, cover slightly with fine mould, and set the poles at the time of planting. For *succatash* in summer or winter, there is no variety that can be compared with the Lima.

Remedy for Hard Milking.—Mr. Kniskern, of Knox, says that he has tried the plan of opening the teats of cows that milk hard, with a harness awl, or a small penknife, as recommended in a former number of the Cultivator, by Mr. Durand, and has by this means made a very good milking cow from one which could scarcely be milked before.—*Alb. Cult.*

Corn and Crows.—As the season for corn planting is approaching, it may be of service to know how to prevent the depredation of crows. Take after the rate of one pound of copperas to a bushel of seed corn; dissolve in water, and sprinkle the corn with it: the corn may at the same time be rolled in plaster. This experiment has been tried now for three years, with great success, by a veteran farmer, and he permits it to be handed us for publication.—*Springfield paper.*

To Destroy Catterpillars.—As soon as the nest can be seen, procure some pure spirits of ammonia, tie a small piece of sponge to a pole that is long enough to reach the highest nests, fill the sponge with ammonia, and once filling will be sufficient to rub off and destroy from 30 to 40 nests.—*American Agriculturist.*

TURNEP SEED.

A SUPPLY of the following varieties of fresh TURNEP SEED just received, viz:

Yellow Sweedish or Ruta Baga, very fine for stock,

Large Globe Turnep, } Fine
" White Flat do. } for
" Hanover or White Ruta Baga do } table
" Norfolk do. } use.

For sale in quantities to suit purchasers, by
Aug. 30 18-tf WM. HAINES, Jr.

GARDEN AND FIELD SEED.

A GENERAL assortment of fresh and genuine GARDEN and FIELD SEED, among which are the following:

Red and White Clover,
Blue and Green Grass,
Rye and Orchard do.,
Timothy and Herds do.,
Millet and Lucerne do.,
Seed Corn of every valuable variety,
Seed Wheat,
Buckwheat and Potato Oats,

Kept constantly on hand by the subscriber, all of which are offered for sale at very moderate prices. All orders, by mail or otherwise, executed with neatness and despatch.

VOL. II. AUGUSTA, GA., MAY 29, 1844. No. 11.

From the Baltimore American.

ANNUAL REPORT OF THE COMMISSIONER OF PATENTS.

The last annual report of the Hon. HENRY L. ELLSWORTH, Commissioner of Patents, is a valuable document. It covers 335 large octavo pages, closely printed, and should be in the hands of every farmer, mechanic and manufacturer in the country. There were granted in 1843 no less than 531 new patents, and 446 expired during the same time. The applications for patents during the same period numbered 819. The whole number of patents issued by the United States, up to the commencement of the present year, was 13,523. The receipts of the Patent Office during 1843, were $35,315; the expenditures $24,750; the sum returned to persons making application, whose claims to patents were denied, $5,026. There were expended during the year, for the restoration of models, records and drawings, destroyed by the burning of the old Patent Office, $4,586.

The report estimates the present population of the United States at 19,183,583; increase since 1840, 2,114,130 souls.

A mass of information relative to the recent improvements in Agricultural processes, implements, machinery, &c., and in the useful arts generally, is embodied in this document, in a manner which commends the subjects treated of to the consideration of the reader in an especial manner. It abounds in Agricultural statistics; and among these we notice an interesting statement of the duties levied on the agricultural products of the United States by the different nations of the civilized world. The Agricultural products of our country for 1843, are estimated as follows.

Wheat, bushels	.....	100,310,856
Corn,	.....	494,618,306
Oats,	.....	145,929,966
Rye,	.....	24,280,271
Barley,	.....	3,220,721
Buckwheat,	.....	7,959,410
Potatoes,	.....	105,756,133
Flax and Hemp, lbs	.....	161,007¾
Hay, tons	.....	15,419,807
Tobacco, lbs	.....	185,731,554
Cotton,	.....	747,660,090
Rice,	.....	99,879,145
Silk,	.....	315,965
Sugar,	.....	66,400,310
Wine, gallons	.....	139,240

A full account is given of a process, hitherto a secret, by which butter may be kept for years, fresh and sweet, in any climate, which we subjoin:

It has been discovered that most kinds of wood contain considerable quantities of pyroligneous acid, which decomposes salt in butter kept in suchtubs. The linden, or bass wood, is the only one which, it appears by careful experiment, is free from it; others, it is stated, may be freed from it, and thus rendered suitable, by boiling three or four hours, well pressed under water. Much importance has always been attached to the preparing of butter, so that it will keep on board of ships at sea and in warm climates. A simple process is now practised, which is said to be effectual for this purpose; which is, to have good butter well churned, and worked and packed hard and tight in kegs of seasoned white oak; the head is then put in, leaving a small hole into which brine is poured to fill the vacant space; and of so much importance is it deemed, to prevent any bad taste, that the plugs for the hole must not be made of cedar or pine, but of cypress or bass wood, as otherwise it would be injured. After which, these kegs are placed in a hogshead well filled with brine of full solution, that will bear an egg, which is then headed up tight and close. The importance of this subject may be estimated from the fact that, as it appears, the standing contracts for butter, in our navy, that will keep at sea, are at twenty-six cents per pound, and for cheese twenty cents per pound. It is now put up of good dairies in Orange county, and keeps perfectly.

The appendix to the report contains a letter addressed to Mr. Ellsworth by G. Fox, Esq., a merchant of Hartford, Conn., corroborating the above.

The mode or process of making "Bommer's Patent Manure," which has been patented here, is described in the Report.

Accounts are also given of many new and valuable plants, and improved varieties of grains, grasses, &c., which possess no ordinary interest for the farmer.—Twelve thousand packages of seeds were distributed from the Patent Office during the last year, "and when we recollect," remarks the Report, "that the improvement of ten per cent. by the selection of seeds would increase the value of the agricultural products of this country, $30,000,000 annually, the attempt thus far made by this office must be deemed a good beginning for still more extended benefits."

Mr. Ellsworth makes mention of a hardy kind of *rice* which flourishes on the edge of the snows of the Himalaya mountains, and states that he has ordered some of the seed, which he hopes to receive before long for distribution.—The opinion is now entertained both in Europe and in this country that upland rice may be raised wherever Indian corn will ripen.

A very interesting account is given of an extraordinary grain called the multicole rye, raised in the west of France, the prolific qualities of which almost exceed belief. A few bushels of it, imported by Mr. E., have been distributed.

The report remarks that "the advancement of the arts from year to year taxes our credulity, and seems to presage the arrival of that period when human improvements must end." We annex a few extracts from the report respecting a few of the most important improvements and inventions of the past year:

In the operation of new furnaces recently erected in the Patent Office to warm it a curious effect is produced by particular ventilation, and deserves remark. Ventilation is often obtained through the ceiling only; but, so far as it respects rooms heated by hot-air furnaces only, this method is an incorrect one. If the temperature of the different parts of the room is tested by a thermometer, it will be found that the upper part heats first; and if no outlet is given, the draught of hot air ceases, the room being filled. Let an aperture be made at the top of the room, and the warffi air instantly escapes; but if an opening is made near the floor, the cold air within the room passes out, and the warm air descends to fill the space. An experiment, proving this, was tried in drying clothes in a room without ventilation, heated by air furnaces; the clothes that were in the upper part of the room dried well, while those in the lower part still continued moist. As soon, however, as an aperture was made for ventilation below, a draught was given to the furnace, the cold air expelled, and the clothes dried rapidly. The public will thus see how easily a serious difficulty in heating rooms may be overcome.

Some facts have been collected respecting plank roads. By means of a preparation, by exhausting the air, and then infusing sulphate of iron or other substances into the pores of wood for rail roads, it is said the wood has been rendered so hard that the iron wheel of the car leaves no trace after more than a year's use of this "metalic" wood.

By a valuable machine, with ten yoke of oxen and five hands, a ditch of suitable depth for draining lands, (14 inches deep, and 28 inches wide at the top,) ten miles may be excavated in one day, at an expense by contract, of not more than three cents per rod. A larger machine, with a greater number of oxen, will excavate a ditch three feet deep. The great importance of such an instrument on the prairies of the West will at once be seen and acknowledged.

The rapid improvement of the arts may help to account for the reduction of price as to many articles of manufacture, and especially in some that are usually ranked among the necessaries of life. Individuals now in Congress can recollect of having, thirty years since, purchased shirting at 62½ cents per yard, who the last year have bought that which was equally good for 11 cents per yard only.

Hoisery, too, is now made in this country with astonishing rapidity, by the aid of the power weaving loom—an American invention, and which has not yet been introduced into England. While there is a full day's work to knit by hand two pairs of drawers, a girl here (at $2 50 per week) will make, by the power-loom, twenty pairs in the same time. A piece 28 inches in width, and 1 inch long, can be knit in one minute.

The expense of manufacturing this article has thus been reduced to about one-tenth of the former method by hand-looms. The importance of this improvement may be estimated from the fact that the quantity of hoisery used in the U. States is valued at $2,500,000; and the stockings, woven shirts, and drawers made in this country, at $500,000.

The little article of hooks and eyes is another illustration of the same progress of inventive industry. Thirty years ago, the price was $1.50 the gross pairs; now, the same quantity may be purchased from 15 to 20 cents. At one establishment in New Britain, Connecticut, 80,000 to 100,000 pairs per day are made and plated by a galvanic battery, or the cold silver process. The value of the article consumed in a year in this country is said to be $750,000.

Another article very essential to the husbandman, *horse shoes*, furnishes a similar proof of the bearing of the progress of inventions. An improved kind of horse shoes made at Troy, New York, for some time past, is now sold at the price of only five cents per pound, ready prepared, to be used in shoeing the animal. At a factory recently erected, fifty tons of these are now turned out per day; and it is thought they can be made and sent to Europe at as good a profit as is derived from American clocks, which have handsomely remunerated the exporter.

We shall content ourselves for the present with a notice of another improvement, which the

intelligent author of the Report thinks a very important one—namely, the construction of cheap cottages of unburnt brick. Unburnt bricks have been found undecaved and sound in arches in Egypt which have even stood the lapse of 2000 years. The cottage erected by himself at Washington, in view of the Capitol, and which is two stories in height, stands well, appears as handsome as the best houses built of burnt brick, is warm in winter and cold in summer. The experiment has been successfully tried in Canada.

DANA'S PRIZE ESSAY ON MANURES.

Section Fifth.

Of the Action of the Salts of Cattle Dung.

Here it is we find ourselves thrown on a sea of opinions, without chart, compass, or pilot, if we trust to the conflicting theories which have been set up for land marks and light houses. Let us therefore, reader, trust to ourselves, aided by the little chemistry we have learned from the preceding remarks about the composition of salts.

I have endeavored to impress on your memory, that the term salt is very comprehensive. But then, to encourage one, it is also to be remembered, that salts are compounds of alkalies, earths, and metals with acids. Now the earths, alkalies and metals, may be united to each of the known acids, (and their name is legion,) yet you may not, by this change of acids, alter the nature of the earth, alkali or metal. That always remains the same; every time you change the acid, you alter the character of the salt. Thus soda may be united to oil of vitriol and form Glauber's salt, or to aquafortis and form South American saltpetre, or to muriatic acid and form common table salt. The soda is called the base or basis of this salt; that is always soda—you do not change its character by changing the acid. To give another example:—lime may be united to carbonic acid and form chalk, or marble, or limestone, or it may be united to oil of vitriol and form plaster of Paris, or to phosphoric acid and form bone-dust. Now, in each case, the base of the salt, that is, the lime, remains unchanged; but, changing the acid, we change the nature of the salt, and of course its effects will be different. Now it is plain, that where the base of the salt remains the same, that will always act the same, but different effects will be produced by different acids. Each base acts always one way, but each has an action similar to every other. Each acid acts also one way, but each has an action distinct from every other: impress this on your mind. Reflect upon it a moment, and you will perceive that salts produce different effects according to the nature of their acid. Now this may be illustrated thus: you take every day, probably, with your every meal, common salt, that is, soda, a base, united to muriatic acid. Your digestion and health are all the better for it. You give your cattle a little salt: it does them good. Suppose now you change the acid of that salt, leaving soda, its base, in the same quantity you daily take. Instead of the muriatic, suppose you substitute the nitric acid, or, what is the same thing, suppose you use saltpetre, from Peru, instead of common salt. You need not be told that you would poison yourself and your cattle by so doing. You can drink, I dare say you have, cream of tartar punch. You feel the better for it. It is refreshing, cooling, opening. Now, cream of tartar is a salt of potash: it is potash and tartaric acid. You have a fever: your doctor gives you a sweat with Silvius's salt, that is, acetate of ammonia, a salt composed of that and vinegar; or you take perhaps an effervescing draught, formed of lemon-juice and pearl-ashes. All does you good: but suppose now you change these cooling, vegetable acids for a mineral acid, say oil of vitriol. You may not take potash united with a dose of oil of vitriol equivalent to the tartaric acid in the cream of tartar, without serious injury.

So is it, reader, in farming: the acids of some salts are not only harmless, but beneficial to plants; others are actual poisons. In the first case salts help to nourish plants, as common salt helps to nourish yourself; in other cases they poison plants, just as they would impair your constitution, perhaps kill you. But it is to be remembered, as in our own case, even those that poison, in a small dose become medicines, so, in plants, a small dose is not only good, but truly essential. Now, if we divide the acids into two classes, the nourishers and the poisoners, such will also be the nature of the salts. When we therefore attempt such a general division of the salts, it may be said that all the acids derived from the vegetable kingdom are harmless; so are the acids called mineral, yet whose components are in part like those of the vegetable acids; for instance, aquafortis or nitric acid. But the true mineral acids are poisonous, such are oil of vitriol and spirits of salt. One thing is here to be borne in mind: It must never be out of sight, in trying to understand how salts make plants grow. You cast your salt upon the ground, it lies there, no action occurs. It rains. Your salt is dissolved and disappears; it seems to do no good. Cast your salt now among sprouting seeds, and growing roots; here is life; well, now, life is just as much a power or force as electricity is. It exerts its force, no matter how, that is quite another consideration. I say, life exerts its force here to separate the acid and the base of a salt, just like a chemical force. We can and do separate the components of salts by other substances, nay, we do it by electricity alone.

Now this is all which it is necessary for you to know, and to understand about this action of plants upon salts: it does disunite the components of the salts. What is the consequence? The alkali, earth, and metal act as such, the same as if no acid was present. The acid also acts by itself; if it is a nourisher, it helps the plant; if it is a poisoner, it hurts it. It produces either a healthy, green crop, the effect of alkali, or a stunted yellow, sickly plant, the effect of acids. Now, neutralize this acid—kill it—and you see your crops start into luxuriance, and you reap where you have strewed. So much for illustration.

Let us now apply this view of the action of salts to those contained in cattle dung. In the first place, we have salts of potash, of soda, of lime; these are the most abundant and active. Then we have salts of iron, manganese, of clay and magnesia. These last, existing in small proportion, may be thrown out of the account, bearing in mind, however, that, though we set these aside, a plant does not; they enter equally with the others into its composition. Let us begin with the salts of potash It is found combined in cattle dung, first, with a vegetable acid, the acid of mould. It is a nourisher of plants. Secondly, with sulphuric acid or the acid of sulphur, called oil of vitriol. This is one of the poisoners, existing only in small proportion in cow dung: it ministers to the wants of a healthy plant. The same is true of the common salt or the muriate of soda of dung. If it existed in larger quantities it would poison the plants to which it might be applied. The next salts are those of lime, phosphate and sulphate of lime, or lime united to sulphuric and phosphoric acid, forming plaster and bone-dust. The acids here, if abundant, would have a decided bad influence—they are poisoners: but the carbonic acid in the carbonate of lime, is a nourisher. Now, from the small quantity in which these all exist in cattle dung, they act only beneficially. But if you apply a great excess, even of cattle dung, you may be sure of an unfavorable result. It will be produced by the acids of those salts which we have called poisonous. To continue our remarks on the acids of salts of dung, it is to be observed that they act also upon the soil.

They decompose that. That is, they extract from the soil alkalies or other substances, like those in the original salt. Now, though applied, as they must be, in very small doses in cattle dung, yet, because of their decomposing action on soil, they continually renew themselves, they last till all their acid is taken up to supply the wants of growing plants.

Let us now, reader, if you understand how the acids of the salts of dung act, turn to the bases or the alkalies and metals and earths of these salts. What is their action? What purpose do they serve in dung applied as manure? First, they enter into and form a part of the living plant: they form a part of its necessary food as much as do the constituents of mould. Secondly, when these alkalies and metallic bases are let loose, by the disuniting power of a growing plant, then they act as alkalies upon mould. They hasten decay, render mould more soluble, fit it to become food for plants.

This account of the action of mould and salts in cattle dung, may appear to you, reader, long and hard to be understood. I do request you not to pass it over on that account. A patient reading—perhaps some may require two or more readings—will put you in possession of all you need to know, to understand the why and the wherefore of the action of mould and salts of whatever manure may be used. What has been said of the action of mould and salts in cattle dung, is equally applicable to all manures. If, then, you bend your bones to this subject, and master it, your labor of understanding the action of other manures, will be reduced to the mere statement of the several substances which they may contain. We therefore proceed to point out other manures, composed of the droppings of animals.

—

Section Sixth.

Of Night Soil, Hog Manure, Horse and Sheep Dung.

These have not all been analysed with the same degree of care, and as often, as has cattle dung. Some, as for instance, night soil, have been examined thoroughly but once. Now, it is not quite fair to base our reasoning upon these single analyses, and say that this or that manure contains this or that salt in greater or less quantity than another.

The quantity and kind of salts are materially affected by several circumstances, which will be considered in the next section. An analysis made when the animal is fed and worked one way, will vary from the result which would be obtained when the circumstances are varied. It is, therefore, quite useless, in the general consideration of the composition of manures, to enter upon the details of each. General results, general expressions of facts, are sufficient for understanding the nature of animal droppings. It is well ascertained, however, that all these droppings, of various animals, contain essentially the same salts as does cattle dung, They all contain portions of each of the substances which form plants It will be enough for the purpose of this Essay, to present to your eye, reader, a table, showing the proportions of water, mould, and salts, which the dung of yourself and your stock contain

	Water.	Mould.	Salts.
Night soil & hog manure,	75 30	23.50	1.20
Horse dung,	71.20	27 00	.96
Sheep dung,	67.90	22.50	3.06

(To be continued.)

From the American Farmer.

ROOTS vs HAY.

We take the following from a report made to the Massachusetts Agricultural Society, by the Messrs. Colts, of Pittsfield, Berkshire Co., and we do it to show the immense advantage made in substituting roots for hay in feeding cattle, as well as in the quantity of ground necessary to produce a given quantity of food.

The writer says—"My stock now consists of 1000 sheep, 8 young oxen, 6cows, a pair of horses, and a single horse. I have raised this season for the use of my stock 5544 bushels of vegetables, and all to be grated and fed out with cut straw, the cattle constantly, the sheep one feed a day, which seems to be a necessary food in our long cold winters: it keeps them in health and also in flesh. As to the respective value of the vegetable food, the following statement will per-

haps be t exhibit it. I have commenced feeding and shall continue to feed—

14 head of horned cattle with 20 lbs. of cut straw each per day, 4 cents for each 20 lbs. 56 cents. Also to each, 8 lbs. of roots grated, mixed with straw, 3 cents, 42 cents. And now allow 150 days for the season of feeding at 98 cents, is $147. The same stock would require 20 lbs. of hay each per day for 150 days; they would consume 42,000 lbs., equal to 21 tons; at the moderate price of $10 per ton, $210. Balance in favor of root feed $93, and I am sure the stock will appear far better at the opening of the spring.

You will perceive that the respective value of vegetables for food is six cents a bushel, while hay is at ten and straw at four. It may be said there is some cost in preparing f od, but this is more than compensated if properly done, by the extra quantities of manure made."

Thus it appears that 20 lbs. of straw, and 8 lbs. of roots, mixed, afford more nutriment, and of course are more valuable than 20 lbs. of good hay, while the actual cost is much less.

14 tons roots is a moderate crop per acre, while the average of hay will fall considerably below two tons per acre. The advantage in favor of the turnep is thus perfectly apparent, and the farmer who persists in mowing his twenty or forty acres, which would furnish roots sufficient, if mixed with the straw which might be grown on the remainder, to keep his animals far better than the hay, and leave the grain crop nearly a clear profit, is clearly acting against his true interests.

Again we say to our farmers, you did well last year by so extensively entering upon the culture of roots; you will do better this year by greatly extending their cultivation."

Communicated for the Southern Agriculturist.

ON THE COTTON GIN, AND THE INTRODUCTION OF COTTON.

Answers to queries of Hon. W. B. Seabrook of Edisto, S. C., by Thos. Spalding, Esq. of Sapelo, Geo.

Sapelo Island, Jan. 20th, 1844.

Dear Sir: Your letter of the 10th inst. was received two days ago, and I was gratified at the communication, as I have long wished to be personally acquainted with some of the gentlemen of your immediate district; your pursuits, your habits, and your opinions, appearing to be in accordance with my own; and nothing but the continued pressure of a painful disease, of now ten years standing, has prevented me carrying out my design, by visiting you.

I will now proceed to answer your queries, in the order in which they are placed; only begging you to remember, if you notice any indistinctness in my answers, that I have only a few days since recovered from a very severe illness which prostrated both body and mind.

1st. Eve's Gin was invented by Joseph Eve, who lately died at Augusta, somewhere about the year 1790, in the Bahama Islands, where Mr. Eve then resided.

Mr. Eve was the son of a Loyalist from Pennsylvania, who had been the friend of Franklin; and Jos. Eve was himself qualified to have been the associate and companion of Franklin, or any other; the most enlightened man I have ever known. His Gin consists of two pair of rollers, more than three feet long, placed the one set over the other, upon a solid frame that stands upon the floor, inclined at an angle of about thirty degrees—so that the feeder may the more easily throw the cotton in the seed by the handful upon a wire grating that projects two inches in advance of the rollers, just below them; between these projecting wires, the feeding-boards, with strong iron, or in preference, brass teeth pass, lifting the cotton from the wire grating, and offering it to the revolving rollers. The feeders should make one revolution to every four revolutions of the rollers. The rollers are carried forward by wheels supported over the Gin, and upon the axle, or shaft of these rollers; at the centre, there is a crank, similar to a sawmill crank, the diameter of whose revolvement, is as one to four of the diameter of the wheels, carrying by bands the rollers.

It is the crimping produced by the teeth and the wire grating, which has served as a cause for carping by the cotton-buyers, and which has gradually led to the disuse of these Gins, the only Gin efficient for the cleaning of long cotton, which has ever been used in this or any other country. With Mr. Eve's Gin, as originally sent to this country from the Bahamas, the rollers were ⅞ of an inch in diameter, made of stopper wood, a very hard and tough wood, and they were graduated to make 480 to 500 revolutions per minute, depending of course, upon the gait of the horses or mules, within these limits. Soon after Mr. Eve first sent his gins to Georgia, some of his own workmen followed them, and began to make them on their own account. To show as much change as possible in the Gins, beside the other alterations, they increased the size of the rollers. they increased the sizes of the roller to ⅞ of an inch, and increased its velocity to six hundred times in the minute. These two changes, while it greatly increased the quantity ginned, very much injured the appearance of the ginned cotton. Mr. Eve had expected and guaranteed to the purchasers of his gins when well attended, in fine weather, from 250 to 300 lbs. of cotton in the day. I have known these altered gins, do sometimes six hundred, but the injury was greater than the increased quantity warranted, add to which the quicker movement of the feeder made the more impression upon the cotton passing from the feeder to the roller.

2d. The first bale of Sea-Island cotton that was ever produced in Georgia, was grown by Alexander Bisset, Esq. of St. Simons's Island, and I think in the year 1778. In the winter of 1785 and '86, I know of three parcels of cotton seed being sent from the Bahamas, by gentlemen of rank there, to their friends in Georgia; Col. Kelsall sent to my father a small box of cotton seed; the surveyor-general of the Bahamas, Col. Tatnall, sent to his son, afterwards Governor Tatnall of Georgia, a parcel of cotton seed; Alexander Bissett's father, who was commissary-general to the Southern British Army, sent a box of cotton seed to his son, in the year 1786; this cotton gave no fruit, but the winter being moderate and the land new and warm, both my father and Mr. Bissett had seed from the ratoon, and the plant became acclimatized. In 1788, Mr Bissett and my father extended the growth, but upon my memory it rests, that Mr. Bissett was the first that found the means of separating the seed from the cotton, by the simple process of a bench upon which rose a frame supporting two short rollers, revolving in opposite directions, and each turned by a black boy or girl, and giving as the result of the day's work five lbs. of clean cotton. What disposition Mr Bissett made of his cotton I know not, but as he was a sensible man, and his father had returned to England, I think it more than probable that he shipped it there.

3d. When cotton was first grown it was planted upon the flat land at five——apart, it was quite too thin, and although the plant grew generally well, the product rarely reached one hundred lbs. per acre, and at four acres to the hand, gave about four hundred to the labor.

My father died in the year 1794, leaving me some property at St. Simons's Island; a gentleman who had been his friend, came for his health, to spend the winter of that year in Georgia, he gave his advice freely to all he saw, that were growing cotton; I was young, he had been the friend of my father, I listened to his advice, left 8 or 10 plants where one had grown; and made off a small field of sixty acres, 350 lbs. to the acre. The revolution was accomplished and the crop greatly increased.

4th. No manure was used for many years in the culture of cotton, persons depending upon the in-field, and the out, or the alternate cultivation of the field, which was soon found necessary. The first suggestion of manure upon a large scale to cotton, came from Col. Shubrick, of S. Carolina, who recommended in some essays in the papers, the application of the drifted reck, that is thrown up by the tides. After the hurricane of 1804, I bestowed a great deal of labor in spreading this reck between my cotton rows over several hundred acres; whether the sea had left too much salt, or whether there was too much in the material itself, I know not, but I neither then, nor afterwards, experienced much benefit from the application.

5th. The plow was but little used for any purpose at St. Simon's; it takes many years before the Palmetto, and the collateral roots of the Live Oak, make hammock land free to the plow. Major Butler did use the plow with mules for both purposes.

6th. The cotton was generally worked four times; we soon found that our working should cease, as soon as the rains became heavy, say at the middle or end of July.

7th. The ridges were renewed every year, or every other year, whenever the field was planted in cotton; they were originally low, and rather small; they were increased in height and breath, according to the different opinions of men.

From the year 1798 to 1802, the St. Simon's cultivation had assumed a regular form, and was in my opinion, good; twenty-one rows to the 105 feet, the ridge occupying the entire space, large but full and flat upon the top. The cotton seed drilled, and the plants thinned, from six to ten inches apart, dependant upon the expected growth of the plant. Major Butler, and Messrs. Couper & Hamilton who cultivated extensively near me, were in the habit of topping the cotton in August, to retain, as they supposed its fruit. I was in the habit of taking off the top of the plant, when the cotton was from 15 to 18 inches high, to make it branch and give a better head.

Twenty years ago, upon purchasing some river land, opposite to Savannah, I adopted permanent ridges, planting a row of corn, and a row of cotton alternately; these ridges had stood nine years, when my son sold the plantation, giving, as I think, the best cotton, and the best corn crops in Chatham county. And this course, I consider the nearest approach to Flemish husbandry, I have known in Georgia; because, although the corn and the cotton changed alternately from ridge to ride, the entire field was kept in full culture, preventing the growth of grass and noxious weeds.

8th. Accounts were kept in pounds, shillings, and pence, in those times, cotton brought at first 14*d.* sterling, but rose gradually in about four or five years, to two shillings, at which it stood, until the unfortunate dabbling with commerce commenced in the year 1806. The first non-importation act, passed in that year, and none more active in its adoption, than our southern men. There were but five men, south of the Potomac, who voted against it, Randolph, J. M. Garnett, Thomson of Virginia, Standard of North Carolina, and myself from Georgia.—From that day to this, the agriculture and commerce of the country has been at the mercy of speculators.

9th. Care was taken for many years, as much as possible to separate the seed, carrying any fur from the black seed, intended for planting.

10th. The St. Simon's cotton stood first, and Maj. Butler's and my own first among them. From the character of the tradesmen attending his gins, or the greater strictness of his manager, his cotton soon took a preference, which it preserved for some years. The staple of the St. Simon's cotton, was thought better than any other; the putting up of Maj. Butler's cotton placed it at the hands of others.

11th. The bags were packed as now with the pestle. I never knew the screw used for long staple cotton but at Mr. Hamilton's plantation, and it was soon given up.

12th. The green seed cotton, was for some years packed with the pestle, in fact I remember to have heard objections made to the screw, and square bales, at their first introduction.

13th. Negroes were worked in task-work, in Carolina and Georgia upon the sea-coast, from my earliest recollection. The task in listing,

the fields being previously cleared up, and the remains of the former year burned off, was half an acre; the laborer was required to ridge afterwards, when carefully done, ⅝ths of an acre; and in hoeing, half an acre was the task, depending, however, much upon the season, and the condition of the field.

14th. The bags generally were expected to weigh 300 lbs. Major Butler's were 4¼ yards and contained 260 lbs.

15th. The rust did not appear for some years in our fields, and when it did, I attributed it to listing in green vegetable matter in the latter summer, for the next year's crop; or coarse vegetable matter in the winter, instead of burning off, which left a light top dressing of ashes. The caterpillars made their appearance, I think, for the first time, in 1793, and destroyed the crop. I remember Maj. Butler made but 18 bales of cotton from 400 acres. There was also a red bug, a winged insect, with a long proboscis, with which it pierced the green pods, extracting the juices of the seed and leaving the pod blighted and hard, and the cotton stained of a deep yellow or red color. In new lands this insect was very destructive, as it had been in the Bahamas, and as it found protection against the cold in the bark and roots of the trees, it was apt to remain for years injuring the quality and reducing the quantity of the cotton.

16th. The cat erpillar was first seen to do injury as I think in 1793, the injury was unusual, the destruction complete, so as scarcely to leave seed. The destructive caterpillar, is not the same that feeds upon the Indigo; the green caterpillar I have frequently known to riddle the leaves, to a great extent, without great ultimate injury, but it is the black and yellow striped caterpillar, that in a few days, say from four to five, will spread over hundreds of acres, not leaving a green leaf, and finally, nothing but the full grown pods, which they sometimes break and injure.

17th. The black seed cotton had been shipped for several years, before they began to grow in the interior the green seed for sale.

I remain, dear sir, respectfully,
Your ob't. serv't.
THOMAS SPALDING.

From the Delaware Journal.

ROOT CULTURE.

A paper on the culture of Roots, read before the "Practical Farmers' Club," by one of its members, at their March meeting:—

No crop is more important to the farmer than the Root Crop, and yet how very seldom in this section of country we see it sufficiently appreciated. At the head of this valuable family stands the Ruta Baga or Swedish Turnep, being first in my opinion, for the following reasons: the seed is put in the most readily, less liable to injury from the insect when young, requiring less expense in the culture, not injured by the early frosts, keeps better through the winter, and last, though all important, yields the most certain crop.

I have been cultivating them for the last 13 years, from one to five acres annually, and like all other crops with different success, but never until this last year an entire failure, (when, from some cause, almost all our root crops were lost;) nor do I think I have ever raised much over 600 bushels per acre, taking the whole crop together; no doubt, by selecting a few square yards of the best, (as is too often done in reports of crops,) and making the calculation at that rate per acre, I might have doubled that amount. Perhaps it may have been from want of proper culture, manure, or some other cause, that I have not obtained a larger yield, for we frequently see statements of crops reaching from 1000 to 1500 bushels per acre. At page 61, volume 1st of the "Farmer's Cabinet," you will find the statement of a crop of one acre grown in this county, from which two tons of hay were cut before planting; then $58 worth of manure spread on it, which, with the preparation and labor with the crop, &c., brought the expenses of it to $83 55—still the yield handsomely remunerated it, being 850 bushels, which at 16 cents per bushel, (the price obtained for part of them, the balance being consumed on the farm,) makes $136: two tons of hay sold for $34, and 4 tons of tops estimated at $8, makes a total of $178—from which, deduct the expenses above, and we have a clear profit of $94 45 from one acre; besides which, the land is left in fine condition for any other crop to follow.—Also at page 171, volume II, same work, is an article from Mr John Sanford, of New York, who says "his business is to work not to write," but he gives us his experience with the Ruta Baga in a very satisfactory manner; he planted three acres in drills on the 26th and 27th of June, hoed but twice, and the yield was 3000 bushels, being 1000 bushels per acre,—he adds that "he thinks they draw more nourishment from the atmosphere and less from the ground than any other vegetable, leave the ground in finer condition and cannot be too highly valued." He also adds, "let all raise according to his wants and means of feeding, depending on his own market, and omit raising a portion of other produce which costs him five times as much both in labor and land."

The Rev. H. Colman obtained a premium, in 1830, for his crop of 903 bushels per acre: he "thinks the labor not as much by one-third as required for the Potato crop," and that "three years' experience has increased their value very much as food for either fattening or store cattle, in his estimation."

Mr. E. Tilden of New Lebanon, who has a flock of 1000 of the finest Saxony sheep, says, "I think Ruta Bagas are decidedly preferable to any other roots, and I raised about 3000 bushels last season."

So we might go on to multiply, without number, accounts of the great value of this excellent vegetable; but let every one give it a fair trial for themselves, and I think I can safely predict that, having once made use of them, they will never omit having a good supply on hand. My method of raising the crop has been to have the ground in as mellow a state as possible, by a free use of the plow and harrow, then to throw it into ridges about 30 inches apart; spread the manure in the furrows, then split the ridges, throwing it back again into the furrow and covering the manure. I prefer this plan of manuring to putting it on broadcast; for, with the latter mode, (without it should be very short,) it interferes more or less with the drill—for, as a matter of course, in ridging the ground after plowing in the manure, you cannot avoid throwing it up again, which brings the manure on the top of the ridge. A less quantity will also answer, as the roots strike immediately into and have the whole benefit of it. I have a very light roller for one horse, to which I attached the drill, which finishes the operation, as the roller going before the drill levels it sufficiently for the seed. About the last of June, I consider the proper time for putting them in, and I prefer doing it at two different times, about two weeks apart, as you will not then be so much hurried in working them, giving you time to get through with the first planting before the next is ready: it is also much better to put the seed in the same day you ridge the ground—with a drill it takes about three-fourths of a pound of seed per acre. As soon as the plants are up, go through them with the cultivator, and when they are large enough to be safe from the fly, go over them with the hand-hoe, thinning them from 10 to 12 inches distance, and hoeing over the strip not worked by the harrow; keep the cultivator frequently at work, and give them a second hand-hoeing, so as not to allow a weed to start; and if the season is not very unfavorable, I will almost be willing to guarantee you at least 600 bushels per acre. Postpone gathering them as long as the season will permit, the early frost does not injure them. My plan has been for each hand to pull two rows at a time, cutting off the smaller roots and top, and two of them throwing the roots together in the intermediate furrow, making 4 rows together, which allows room for a cart to pass between in gathering them; they may either be kept in a cellar or buried in the field, as is often done with the potatoes,—do not keep too warm, nor, on the contrary, allow them to be frozen, and they will be firm and good until May.

In feeding, I cut them with a knife made by two blades crossing each other at right angles, fixed on a long handle, which makes very expeditious work, and is superior to any of the many machines I have ever seen invented for that purpose. Many object to feeding them to milch cows on account of imparting to the butter an unpleasant taste; if given to them but once a day there is no danger of that being the case, at least I have never found it so.

Beside the saving to your corn crib, you will also find your stock looking much better from the use of them, as it keeps them in a much more healthy state than when confined the whole winter on dry food, they also eat their hay and other provender much better from having a change.

The Sugar Beet, Mangel Wurtzel, Carrots, Potatoes, and many others of this valuable family, all have their advocates and all are excellent; only be sure to raise some of them, which ever you prefer. I have given you my experience with my favorite, and shall be gratified if I can induce some of you who have never yet tried it, to give them a trial.

N. B. If you do not wish to go to the expense of purchasing a drill, you can put them in very expeditiously, by levelling the ridge with a rake, making a small furrow with a stick, and sprinkling the seed in it from a bottle, having a quill through the cork, which can be regulated by the finger being kept on it, and then covered with the back of the rake.

From the American Farmer.

ALTERNATION OF CROPS.

This is unquestionably one of the best and most economical means of preserving fertility, and of increasing the profits of the farm. All crops exhaust the soil more or less, of the general elements of fertility, though all do not exhaust it alike of certain specific properties. It is believed that every plant requires a specific food, which other families do not stand in need of, and which they do not take up. This is evidenced by the fact, that wheat cannot be profitably grown on ordinary land, in two successive years, upon the same field, without a great falling off in the product. And it is now laid down as an axiom in good husbandry, that two crops of any small grain should never be taken from the same field in successive years, because they draw too largely upon the same specific food. But after an interval of four or five years, in which grass and roots intervene, the specific food of the wheat crop has so accumulated in the soil that this grain may then again profitably be grown upon it. So with all other crops, not even excepting the grasses. The law of nature's change in the products of a soil is so palpable, that in Flanders and Holland, where flax is one of the profitable staples, they do not think of cultivating this crop upon the same ground oftener than once in ten or twelve years. Our farmers, some of them, seem to appreciate these truths in reference to tillage crops, without duly reflecting that they apply as well to grain. Meadows, too, deteriorate; in a few years the finer grasses run out, because the soil becomes exhausted of the particular food which affords them nourishment, coarse or innutricious plants take their place and the herbage becomes inferior in quality.

Upon an average, old established meadows would yield double their present crops, if judiciously alternated with grain and root crops. The terms "suitably divided into meadow, plow and pasture lands," which are generally employed to recommend farms for sale, are an indication of bad husbandry; and very often betray the secret which compels the owner to sell. Excepting in very stony districts, every acre of land which would produce good grasses, may, by being rendered dry and rich, be made to produce good grain and roots. In this convertible

system of husbandry, permanent meadow or plow lands are almost unknown—every field produces in turn, crops of grain, grass and roots.

There are three classes of crops which alternate beneficially with each other, viz: 1st, grain, or corn, or dry crops, which mature their seed and most exhaust the fertility of the soil; 2d, grass crops; and 3d, root or green crops, embracing turneps, potatoes, beets, clover, &c. In old meadows and pastures, not only the better grasses disappear, and coarse herbage and mosses come in, but the soil becomes too compact and hard to admit the free extension of the roots, and the genial influence of the sun, dew and atmosphere, which are primary agents in the process of vegetable nutrition Tillage corrects these evils. It cleans the soil of weeds, and converts them into sources of fertility; it breaks and pulverizes the soil, and fits it for the return of the grass crop at the close of the rotation; while the vegetable matters of the sward contribute to augment the grain or root crop which is to follow. All green crops are more or less fertilizing when buried in the soil; but clover is preferred, as well on account of its enriching properties to the soil, as that it also affords hay and pasture. The practice of sowing clover seed with grain crops is adopted by some farmers every year. Judge Buel followed this plan, but he plowed his field on the following year. The food which this clover affords to the coming crop, richly compensates for the cost of the seed and sowing, to say nothing of the pasture it gives in autumn. Hence, tillage is admirably calculated to fit and prepare the ground for grass, and in return directly or indirectly furnishes an abundance of food for grain or roots. The fertility of a soil depends, essentially, upon its power to absorb water by cohesive attraction, and this power in a great measure upon the state of diversion of its parts—the more divided they are, the greater is their absorbent power. The crop upon a hard compact soil will suffer from drought; but if this soil is finely pulverized and broken, it will suffer much less. The first may be compared to the rock, which receives moisture upon its surface only, the latter to the sponge, which receives and transmits moisture to the whole mass, and which retains it for a long time.

From the American Farmer.

WHAT IS THE PROPER FOOD OF WHEAT?

This is a question much easier asked than answered; for though it has been mooted at intervals from the earliest introduction of the wheat culture, it never has been satisfactorily answered, and we question very much whether it ever will be, so as to render the solution of it generally available; but still we may be able to form something like an approximate opinion through the aid of the laws of analysis. By resorting to these, we find what are the constituent elements of the wheat berry, and hence the inference is, that if we can apply substances to the soil containing these elements, of a soluble character, that we will approach as near as is desirable to furnishing the appropriate food for the wheat plant. The next question to be considered relates to the quantities of the several kinds to be applied to the acre? How far climate may operate to facilite or retard their solution? It is plain that before the rootlets can take up food of any kind, it must be reduced to a liquid or gaseous form, and it is equally plain that this condition of the pabulum from which they derive their support, can only be brought about through the agency of heat, air and moisture, as while all vegetable bodies must undergo decomposition, so must those of a mineral nature be reduced by the dissolving action of water. As connected then, even with the proper quantities, if the proper kinds of manures could be ascertained, the seasons and the climate exert most potent influences, either for good or for evil, in the growth of the wheat, or any other kind of vegetable production; hence what might prove salutary one year, would be otherwise another. But let us consider now of what wheat is composed. By the analysis of Sprengle, a thousand pounds, or say, 16 2-3 bushels of wheat, leave

Of Potash,	225 lbs.
Soda,	240
Lime,	096
Magnesia,	090
Alumina with a trace of iron,	026
Silica,	400
Sulphuric acid,	040
Chlorine,	010
	1127

Thus then, if this analysis be accurate, and Sprengle's reputation is a guaranty that it is, the inference is a fair one, that, as the above constituent elements are to be found in the berry of the wheat plant, the soil should be provided with each and all of the substances enumerated, either in greater or lesser proportions, in order that the preparation of the food of the plant might be going on. In every soil alumina (clay) and silica (sand) are always present, and from the greater quantity of the latter, found by analysis, as a constituent element, we should infer that, notwithstanding wheat is said most to delight in clay soils, still that sand is indispensable to the fructification of the grain. We know that unless there be a sufficiency of potash in the soil to dissolve the silica, and yield it to the plant, that, as a natural consequence, the stem will lack that ingredient essential to enable it to stand erect, and from the evidence afforded by the analysis, we should conclude that ashes, potash and lime, are indispensable to the successful culture of wheat, and that salt would be found to be a valuable auxiliary; nor should we apprehend so much dread as is indulged in by some, if the lime used were of the magnesian kind.

It may be said, that because we find these various substances in wheat, that that is not conclusive proof it derives it exclusively from the soil. We admit this supposition most freely, inasmuch as we are satisfied, that a very sensible portion of the food of plants is derived from the atmosphere, and that this portion is as well appropriated by the leaves as by the roots; by the latter process the most, when, by the organic remains, or mineral manures used, the powers of absorption, retention and assimilation, the soil have been accelerated to activity. From the presence of sulphuric acid, we should take it for granted that plaster is almost as essential to wheat as it is to clover. We are aware that this opinion will not be considered as orthodox by a very large description of farmers, who will tell you that plaster increases the straw but decreases the grain. Now we are not sure that this opinion of theirs is well founded. If, after the use of plaster, such result may have been produced, may it not have sprung from other causes than the use of plaster? May not the weather, an excess of rain, or nutritive manures have produced the result, and not the plaster? If the *theory* of the action of plaster, which strikes us as most rational, be the true one, its most essential office is to *husband* and dole out gaseous food, according to the wants of the plants, rather than to stimulate them by improvident and too luxurious feeding: If this were not the case, we should think that the minute quantity required for an acre, would not answer the valuable and wonder-exciting purpose that it does. If its office, of itself, were merely stimulative, its effects would be less manifest and less lasting, nor would those effects be visible beyond a single season; hence we infer, that, besides its *direct* agency, it exerts an *indirect* one, as a *caterer*, if we may so express ourself, still more important. Again, those who deprecate the use of plaster directly to the wheat crop, do not hesitate to use it on clover, and turning that in with the after-math, to grow wheat on it. Why, then, if plaster exerts so unfavorable an influence when applied as above first stated, is it that when sown on the clover the wheat escapes the assigned injury? This is a question as difficult of solution, as is the one with which we begun this article: for, as the plaster requires many hundred times its own body of rain to dissolve it, it must necessarily continue its action through several seasons and successive crops.

We have thrown out these remarks merely as suggestions, in the hope that the question of "What is the proper food of wheat?" may draw out some able correspondent, whose knowledge, observation and experience, may enable him to throw light upon the subject.

ESTIMATE OF THE CROPS OF 1843.—A tabular estimate of the crops for 1843, has been prepared with much care under the Commissioner of Patents, at Washington, and from numerous sources of information, makes the wheat crop 100,310,856 bushels; barley, 3,220,856 do.; oats, 145,329,969 do; rye, 24,280,271 do.; buckwheat, 7,959,410 do.; Indian corn, 494,618,206; potatoes, 105,765,133 do.; hay, 15,419,807 tons; flax and hemp, 161,007 lbs.; tobacco, 185,731,554 lbs.; cotton, 747,666,090 lbs; rice, 80,879,145 lbs; silk, 315,965 lbs; sugar, 66,400,310 lbs; wine, 139,240 gallons. Pennsylvania has contributed to this amount 12,215,230 bushels of wheat, ten per cent in advance of the year previous; 150,398 bushels of barley; 19,826,938 of oats; 9,429,637 of rye; 2,408,508, of buckwheat; 15,857,431 Indian corn; 9,161,409 of potatoes; 1,899,128 of hay; 3,527 of flax and hemp; 441,944 tobacco; 26,482 silk; 878,730 sugar; 18,983 of wine. The only States which exceed Pennsylvania in wheat are Ohio and New York.

The estimate of Ohio is 18,786,705 bushels; New York, 12,479,499 bushels. The States which exceed Pennsylvania in the growth of potatoes are Maine and New York. The growth of this article in the latter named state is enormous. It is set down at 26,555,612 bushels; Maine, 10,253,521 bushels. The State which produces the greatest amount of barley is New York, nearly ten times greater than Pennsylvania. That which produced the greatest amount of oats is New York, Pennsylvania next, and Ohio next. Pennsylvania has produced three times more rye than any other state; also, the greatest amount of buckwheat. Tennessee produced the greatest amount of Indian corn, the estimate is 67,838,478 bushels. Missouri produced the greatest amount of flax and hemp, 30,300 lbs; Kentucky, the largest yield of tobacco, 52,322,543 lbs; Georgia the largest amount of cotton, 185,758,138 lbs; Connecticut the largest amount of silk, 140,971; Louisiana of sugar, 37,173,590 lbs; and New York next, 6,934,616 lbs. A comparison of the agricultural products of our own with other countries, from well authenticated tables made in 1828 gives the following result:

The number of bushels raised to each soul, was, of grain, wheat, barley, oats and rye in Great Britain, 12 bushels; Denmark, 20; Prussia 12; Austria 14; France 7; Spain 5; United States 18½. There has been a great advance since then both in Europe and this country.—France, in 1841, produced of the grains, 547,550,443 bushels, and the United States, 533,988,970 bushels. The population of France was then more than thirty-one millions, and the U. States over seventeen millions. Thus the proportion of grain in the United States to a person, compared with France was nearly two to one. Similar comparisons with other countries would be greatly in favor of our own, showing that our surplus is the greatest.—*Philad. Ledger.*

From the Albany Cultivator.

SOWING CORN FOR FODDER.

We would suggest the sowing of corn broadcast on rich land for winter fodder. Mr. Sotham, of "Hereford Hall," sowed six acres last year, which he thinks yielded nearly six tons of dry fodder to the acre. He has fed both cattle and sheep with it, (cut with a machine,) the past winter, and is so well pleased with it, that he is determined not to be without it in future. Others, who have tried it, speak equally in its favor. The quantity of seed recommended to be sown per acre, is from two to three bushels. Some experiments made by Mr. Welles, of Boston, seem to show that it is best to cut it soon after the shindle makes its appearance.

For the Southern Cultivator.

REPORT OF THE COMMITTEE ON MANURES. OF THE BOWLING GREEN AGRICULTURAL SOCIETY, IN OGLETHORPE CO., GA.

Your committee, to whom was referred the subject of investigating and reporting on the best mode of raising and applying manures, acknowledge that their experience is so limited, that they are entirely incapable of doing justice to that important branch of Agriculture. Notwithstanding, we beg leave to report—

1st. That, to succeed in raising manure, we should find out what are the different compositions that will ferment and decompose in the shortest time, and in the best manner; and our limited experience is this: to haul upon our farm-yards corn and cotton stalks, leaves from the woods, weeds, rotton wood, &c., and spread them upon the yard—and then cover them with muck or dirt from a pond; after they have been sufficiently trod, dunged and urinated upon, which time must be regulated by the season of the year, it should be thrown into a pit prepared for the purpose, or in pens, taking care, after your heap is completed, to cover it well with muck or pond dirt, to prevent evaporation Your stables should be filled up with the same kind of litter except the muck, and cleaned out once a week; this system would make it more comfortable for your horses, and prevent the loss of a great quantity of urine. The quantity of litter to be placed upon the barn-yards must differ in the different seasons of the year. In the spring, they should be six inches deep, the muck or pond dirt one inch deep. In the summer, the coat or layer of litter and muck should not be so thick, and trod not exceeding four weeks; then raked up and thrown into the pit or pen.

The reason for cleaning up in so short a time is obvious; it prevents the long hot summer day's sun from burning it up, or killing the droppings or dung of the cattle, and the evaporation of the urine, which we believe to be no little item in the preparation of manures. As the season moderates, the layers of litter and muck should be deeper and longer trod. We are of opinion that the above preparation may be continued for Cotton, until the last of February, successfully.

Your committee beg leave, now, to report upon the application of manures.—In the first place, we recommend that the manure be placed in the hill or drill, as deep, if possible, as the clay or subsoil, immediately under the corn or cotton, or any other article, and covered with dirt previous to planting. If for corn, a very small quantity of dirt should be placed upon the manure: if for cotton, it should be bedded upon until the manure is covered from four to six inches deep. The reason that we recommend placing manure in the hill or drill, is owing to the small quantity that we have. If we had a sufficient quantity, by all means the system of throwing it broadcast is the true Agricultural system. All seeds should be planted immediately subsequent to the application of the manures.

In treating upon the subject of manures, cotton seed comes into the account, as it is known to be a great fertilizer. There seems, however, to be as many conflicting opinions and modes in the application of cotton seed as manure, as any other article of manure, if not more. Some contend, (and all say from experience,) that the proper mode is to put the seed in the bottom of the furrow, after the ground is laid off, and then throw a small quantity of dirt upon the seed; then drop the corn and cover in the common way, say with a plow or hoe. Others contend that the seed should be dropped upon the hill immediately after the corn is planted, so we say not until the corn is up, and then they should be placed round the corn and covered with the hoe, which is a weeding or hilling to the corn. Now it follows, of course, that all these modes cannot be right; and, to know the proper mode of applying them, it is necessary first to know the fertilizing properties the seed possess.

This, your committee believe, all will concede, is mostly contained in thin oily substances; if so, the matter is at once settled, for this reason: oil is lighter than water, consequently in a wet time, or when the earth is full of water, the oil will rise, being lighter than water; and in its rising, it has to work its way through to the surface; and in this process, the roots of the corn receive its nourishment, consequently it should be placed deep enough to be below the roots of the corn.

Your committee not being acquainted with the principles of chemistry, nor that of analysing, defers any reference to them; but believes them connected with Agriculture, and do not believe that the true system of Agriculture can be carried out without a knowledge of them.

Your committee believe the practice of heating cotton seed in pens or heaps, as is the custom of the country, entirely at variance with the true mode of preparing seed for manure, as it is conceded that oil is the fertilizing property contained in the seed. You readily discover that heating the seed destroys a goodly quantity of the oil. To remedy this, we recommend that the seed be kept dry under shelter until they are wanted for use; and then, with some simple machinery, the seed be so mashed as not to sprout after they are applied as manure, and be applied in their green state.

All of which is respectfully submitted for your consideration.

JOHN W. MOODY, Chairman.

AGRICULTURAL FAIR.

The Fair of the Bowling-Green Agricultural Society, will take place at the Bowling Green on Friday, the 4th of October next, when the following honors will be awarded:

For the best acre of corn,	1st honor.
For the second best do.,	2d honor.
For the third best do.,	3d honor.
For the best acre of wheat,	1st honor.
For the second best do.,	2d honor.
For the third best do.,	3d honor.
For the best acre of oats,	1st honor.
For the second best do.,	2d honor.
For the best acre of cotton,	1st honor.
For the second best do,	2d honor.
For the third best do.,	3d honor.
For the best Georgia raised mule,	1st honor.
For the second best do.,	2d honor.
For the best stallion, Georgia raised,	1st honor.
For the second best do.,	2d honor.
For the best 3 year colt,	1st honor.
For the second best do.,	2d honor.
For the best mare, Georgia raised,	1st honor.
For the second best do.,	2d honor
For the best bull,	1st honor.
For the second best do.,	2d honor.
For the best cow, producing the largest quantity of milk, regardless of blood,	1st honor.
For the best ewe,	1st honor.
For the second best do.,	2d honor.
For the best boar,	1st honor.
For the second best do.,	2d honor
For the best sow,	1st honor.
For the second best do.,	2d honor
For the heaviest hog, from 1 to 2 y'rs old,	1st honor.
For the second best do.,	2d honor.
For the heaviest pig, from 6 to 12 months old,	1st honor.
For the second best do.,	2d honor.
For the best home manufactures, embracing all kinds of fabrics,	1st honor.
For the second best do.,	2d honor.
For the third best do.,	3d honor.

On the above day, there will be an Agricultural Address delivered before the Society, by Joseph H. Echols, Esq., of Lexington.

WM. JEWELL, Secretary.

IRISH POTATOES.

A well informed and experienced farmer says, in the Gardener and Practical Florist, that he is well satisfied that the productive power of seed potatoes is much diminished by suffering them to become over ripe, and he gives good reasons for his belief. He digs the potatoes before the vines are dead, and places those intended for seed in pits dug in a shady, airy situation, not more than six bushels in a pit, covers them with straw, and then with earth two to three feet. In greater bulk they may ferment. He says that the great error is late planting and late harvesting; all kinds should be planted very early, and all should be dug as soon as the growth is completed.

From the Southern Planter.

IMPROVEMENT OF WORN-OUT LANDS.

From a very intelligent traveller, whose acquaintance we happened to make as he was passing through our city, we have received the following communication:

FAYETTEVILLE, Cumberland Co., N. C.

C. T. BOTTS, Esq.

Dear Sir,—In passing through parts of Virginia and North Carolina, I was much surprised to see large fields lying waste, which I was informed had been abandoned as "worn out," whilst the proprietor had substituted new grounds for them, at all the expense and inconvenience of a new home and a new clearing. Beside the sacred and endearing associations which usually cluster around the ancient homestead, a great pecuniary loss must be sustained in the pursuit of this system. It would seem that one-half of the time and labor required to fit a new farm of the crop, would restore the old one. A plan for the improvement of old lands is very successfully practised at the North, which, it appears to me, would be applicable here. It is as follows:

Procure as many bushels of buckwheat as there may be acres to improve, and as soon as the spring opens, plow the fields deep and sow the buckwheat broadcast, and harrow it in.—This on the very poorest lands at the North will yield a quick and luxuriant growth.

As soon as the crop is in full blossom, (unless it has grown so rank as to have lodged of itself,) flatten it to the ground by the use of a roller, followed immediately by the plow, which shall whirl it under. Sow again another bushel to the acre upon the unturned soil, rake it in, and as before, turn it under. Then sow the seed of the largest kind of red clover, which should be suffered to grow to maturity, then to be trampled down and eaten off by stock. To all these crops, one bushel of plaster per acre, applied when they are about one-fourth grown, will vastly increase the amount of vegetable matter, and will also secure a more extended fermentation.

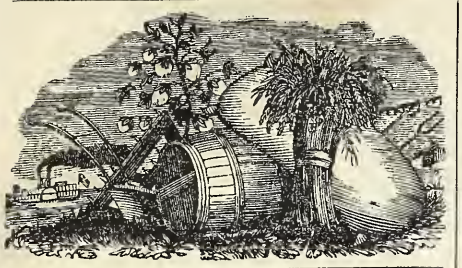
At the end of the second year, all lands thus treated, will be restored to their original fertility. At least, I know from experience that such has been the effect in the more northern sections of the Union, and I do not see why the same result should not follow at the South.

A NORTHERN FARMER.

SIMPLE MODE OF PURIFYING WATER.—It is not so generally known as it ought to be, that pounded alum possesses the property of purifying water. A table spoonful of pulverized alum, sprinkled into a hogshead of water, (the water stirred at the time,) will after a lapse of a few hours, by precipitating to the bottom the impure particles, so purify it that it will be found to possess nearly all the freshness and clearness of the finest spring water. A pail full, containing four gallons, may be purified by a single teaspoon full.

COTTON MANUFACTORY IN CINCINNATI.—The Cincinnati Atlas says that a manufactory for the fabrication of cotton goods is soon to go into operation in that city, under the auspices of three of its most enterprising and respectable citizens, whose known produce is a sufficient guaranty that they have examined the whole ground and are sure of success. The Atlas hails this as an era in the prosperity of the "Queen City" of the West.

☞In cultivating the earth, the condition of man's success is his industry upon it. In raising domestic animals, the condition of his success is kindness and benevolence to them.



WEDNESDAY, MAY 29, 1844.

DANA'S PRIZE ESSAY.—After a suspension of this most excellent essay for the last few numbers of our paper, which was unavoidable in consequence of the misplacing of the only copy we had, we have the pleasure of renewing it in the present number, and shall continue it regularly until completed, unless prevented by a similar occurrence.

ANOTHER AGRICULTURAL SOCIETY.—We hail with pleasure the formation of an Agricultural Society at Busbyville in Houston county, Ga., which we see announced in the Macon papers. The Society was organized by the election of the necessary officers, after which a committee was appointed to draft a Constitution and by-laws for its future government, who should report at a subsequent meeting, which was appointed for the 18th inst.

We avail ourself of the opportunity which this annunciation affords to congratulate the members of the Society upon their organization, and to them singly and collectively the columns of the "SOUTHERN CULTIVATOR" as a medium through which to communicate their views upon any and all subjects connected with the object of their association.

And we take occasion to assure them in common, with all other Agricultural Societies at the South, that it will always afford us a high degree of satisfaction to contribute all in our power to the dissemination of their action upon all matters pertaining to agriculture, or its kindred pursuits, and we earnestly hope they will favor us with whatever they desire communicated to the public, as ours is certainly the most appropriate medium for its first appearance. We trust that this invitation will be considered sufficiently particular and general, not only to the agricultural Societies, but also to all persons who may desire to become contributors to our journal, to induce them to favor us with whatever they may deem of sufficient value to lay before the public.

RAIN.—After an almost continuous drouth for nearly three months, we have the pleasure of announcing that since our last, we have been favored with refreshing and copious showers, which we are gratified to learn from our exchange papers have been very general throughout the country. Although the drouth has been quite protracted for this period of the season, we feel well assured that it can only be productive of good generally should the future be propitious. For it has afforded planters an opportunity to cleanse their growing crops thoroughly, and prepare them for the reception of the genial showers with which we have been favored and of the continuation of which we have now very flattering indications.

EVERY MAN HIS OWN CATTLE DOCTOR, containing the causes, symptoms, and treatment of all the diseases incident to oxen, sheep and swine; and a sketch of the Anatomy and Physiology of neat cattle: by Francis Clater—edited, revised and almost re-written by Wm. Youatt, author of the Horse, &c. With numerous additions on the use of oxen and the improvement in the breed of sheep, &c., by John S. Skinner, assistant Postmaster General: with numerous cuts and illustrations. Philadelphia: Lea & Blanchard. 1844.

A very neat octavo volume, of 251 pages, with the above title, has been sent us by Mr. Skinner; and, in the absence of sufficient leisure to examine its contents thoroughly, we avail ourself of the following notice from that most excellent Agricultural paper, the "American Farmer:"

'As its title would import, it is a most valuable work, and should be in the hands of every American Farmer; and we feel proud in saying, that the value of the work has been greatly enhanced by the contributions of Mr. Skinner. In the selection of his subjects, he has judiciously taken two of the very first importance to the well-being and prosperity of the Agricultural public; for, in our view, nothing can be more so than the use of oxen, and the improvement of sheep. As to the use of oxen instead of horses, in many of the labors of the farm, as a means of economy, there can be no doubt; for no one yet has substituted a well-trained yoke of oxen for a span of horses, that ever found cause to regret the change. With respect to sheep, there is no department of husbandry which needs improvement more, nor none that will repay better for the labor and expense attending such an enterprise Wool is a staple of immense value at the present time as a product of the nation—equal, we should think, to from thirty to forty millions of dollars a year, and may be made more so, as the increasing demand for it by the manufacturers justifies the belief that in a few years, twice the quantity will be needed.

'With then, a present steady and remunerating market for the article, and a prospect of increase and improvement, surely it behooves the farmers to lend their energies not only to the increase of their flocks, but to their *improvement* also, as the sheep which bears *good wool* is as easily and cheaply raised, as one that produces an inferior article, whereas the profit on the staple is greatly in favor of the former.

'We congratulate our agricultural brethren throughout the Union, that our old and esteemed friend, Mr. Skinner, has had a hand in the preparation of this work, as his high order of talents and devotion to the pursuits of husbandry, qualify him to give to the public not only a standard work, but one particularly needed by the necessities of the farming community.—*Clater* and *Youatt* are names treasured by the farming communities of Europe as house-hold-gods; nor does that of *Skinner* deserve to be less esteemed in America, where every farmer, who may at all be conversant with agricultural literature, know that he gave the first impetus to improvement, and has, by his enlightened, untiring devotion to all that belongs to American husbandry, done more to advance its real welfare than any other American writer living or dead. He established the American Farmer, the first Agricultural paper in our country, and from that day to this has given the best energies of his capacious mind to the enlightenment of the public upon matters connected with the enscience of Agriculture. We have always cherished him as a *benefactor* to his country—for none are more entitled to the appellation of being considered such, than he who labors to promote the prosperity of the first of all human callings.

'In conclusion, we commend the book to every farmer and planter, and trust it may find a place in every homestead throughout our land—nay more, that all who may buy it may read and study it well.

EXTRAORDINARY STRAWBERRIES.—Dr. Bayne recently exhibited to the Horticultural Society of Washington city, two jars of strawberries, measuring five inches in circumference, and weighing each two hundred grains; thirty-two of them filling a quart; and for flavor and beauty far surpassed any fruit ever exhibited here. Dr. Bayne has lately given great attention to the cultivation of the straberry, and deserves much credit for having brought this excellent fruit to its present state of perfection.

For the Southern Planter.

EXTRAORDINARY FECUNDITY.

MR. BOTTS—There was an instance of greater fecundity in my neighborhood a few days ago, than I have ever heard of before. Nature made the effort, but the constitutional powers of the animal were not sufficient to accomplish her purpose.

A ewe belonging to Mr. William Applebury, (S. A.) about two years old, became so disabled and diseased from the excessive distension of the uterus, as to make her entirely helpless and apparently dying. Mr. Applebury thought it most humane to have her killed. On examining the contents of the womb, he found four perfect lambs near sufficiently matured for birth. A fine subject for the physiologists.

J. M. W.

CHATHAM, Feb. 17, 1844.

As an accompaniment to the above, we may mention that a gentleman of this city, of the highest respectability, called at our office a few days since and stated, that a sow on his farm in the neighborhood had the evening before given birth to eleven fine full grown pigs, and that about twelve hours after, she produced another litter of ten, about three-fourths matured—evidently the result of a second conception.—ED. SOUTHERN PLANTER.

☞Beware of *little* expenses: a small leak will sink a great ship.—*Franklin.*

CURE FOR A FOUNDERED HORSE.—A correspondent of the Louisville Journal says that if a horse is foundered over night, he may be cured in three hours, if it is attended to in the morning. Take a pint of hog's lard and heat it boiling hot, and after cleaning his hoof well and taking off his shoe, put his foot in the lard, and with a spoon apply it to all parts of the hoof as near the hair as possible. This he has tried for more than fifty years, and never known it to fail. The application should be to the foot of each foundered limb.

The ship Greenock cleared from the port of Mobile on Saturday last, with 4000 bales cotton, being the largest cargo ever cleared from that port. Its weight is estimated at 1,941,091, and its value at $136,163.

HARROWING GRAIN.—We have often (says the American Agriculturist) found great benefit in harrowing grain in the spring of the year, as soon as the ground is well settled and dry, more especially wheat somewhat winter killed. It stirs the earth encourages tilling, and adds to the vigor of the growth of the plant. The harrow should be followed by the roller, so as to replace the roots of the plant which may be laid bare by the harrow, and crowd them in the earth.

The Albany Cultivator says: The horseradish is propagated by sets or by taking the crown of the plant, with a few inches of the root, and burying it in deep rich soil to the depth of eight or ten inches. If the set is split into two or three parts, retaining a part of the crown on each, the plant may be increased more rapidly. Before planting, the ground should be dug and manured to the depth of eighteen inches or two feet. The plants may be set in the spring or fall.

EXPERIMENT.—A Scotch paper says that the Rev. Mr. Ramsay, of Arbroath, commenced digging early potatoes on the 28th of June: after removing the crop, he immediately replanted the stems; and although the first crop was considered good, the second from the stems, was superior, more numerous, larger, and of a better quality. The experiment is worthy of further trial.

CONICAL BRUSHES.—A writer in the New England Farmer recommends a corn-cob fastened to a pole as a good substitute for Pickering's conical brush in removing caterpillars from trees. The editor of the Farmer thinks that any one who allows caterpillars to encumber his trees when he can avoid it by cobbing them, deserves to be "cobbed" himself.

AN INSECT TRAP.—Scoop out the inside of a turnep, scollop the edge of the shell, and place it downward on the earth; the insects will pass into it as a place of retreat, through the holes; and the beds of squashes, melons, cucumbers, &c., may thus soon be cleared of them.

NOVEL METHOD OF WORKING BUTTER.

A correspondent of the American Agriculturist, writing from Montpelier, Vermont, says:

"A very useful and ingenious mode of extracting whey from butter, was recently related to me by a gentleman who had resided many years in the grazing districts of France; and he informed me that a similar apparatus is at present in successful operation, near by here, in this State, although I have not yet seen it. He described it in a manner that could not fail to be understood by any farmer in the Union.

"The machine, he represented as made of wood, in form not much unlike a grindstone, closely fitted into a trough, leaving a space between the stone and bottom of the trough not exceeding a sixteenth of an inch in thickness. The trough is first filled with clean water saturated with salt, one end of which is crowded full of the newly-churned butter. Then the stone is put in motion by means of the crank or otherwise, and the butter is drawn beneath it, and comes out at the other end of the trough in thin sheets, not more than one-sixteenth of an inch in thickness, almost entirely freed from the whey, and for common use requires no further salting. The brine thus prepared, has another very important office to perform. It imbibes, by chemical affinity, all the whey with which it comes in contact, and leaves the butter by itself.

"Although this apparatus is extremely rude and simple, it is obvious to an ingenious mechanic, how easily such a machine could be improved upon, and answer a tenfold purpose."

SOUTH CAROLINA STATE AGRICULTURAL SOCIETY.

In consonance with a resolution passed at the last meeting of the *State Agricultural Society*, the following premiums are offered for stock, at the exhibition to be held in Greenville, on the 2d Wednesday in September next:

For the best Stallion over 5 years old for harness purposes, a silver cup,	$15 00
For the best Stallion, over 5 years old, for saddle purposes, a silver cup,	15 00
For the best Stallion or Colt, under 5 years old, a silver cup,	10 00
For the best Mare or Filly, under 5 years old, a silver cup,	10 00
For the best Mule, over 3 years old, bred by a member, a silver cup,	10 00
For the best Mule, under 3 years old, bred by a member, a silver cup,	10 00
For the best Bull, over 1 year old, a silver cup,	15 00
For the best Bull, under 1 year old, a silver cup,	10 00
For the best Milch Cow, a silver cup,	15 00
For the best Heifer, under 1 year old, a silver cup,	10 00
For the best Boar, over 1 year old, a silver cup,	10 00
For the best Boar, under 1 year old, a silver cup,	5 00
For the best Sow, over 1 year old, a silver cup,	10 00
For the best Sow, under 1 year old, a silver cup,	5 00
For the best Ram, a silver cup,	5 00
For the best Ewe, a silver cup,	5 00

Any citizen of the State, paying 5 dollars before the hour of exhibition, will be thereby constituted a member, and entitled to compete for the premiums. JAMES B. DAVIS, Sec'y.

All the local Societies are requested to send Delegates to this meeting, and Hon. John B. O'Neall is appointed to deliver an address.

Planters are requested to add to the interest of the exhibition, by sending stock to the fair *for sale*, to which the Secretary will *cheerfully* attend.

The following are the awards offered at the annual meeting of the State Agricultural Society, to be held as usual on the 1st Wednesday of the session, in Columbia:

For the best managed Farm, a silver cup,	$20 00
For the greatest product of Corn, per acre, a silver cup,	10 00
For the greatest product of Short Staple Cotton, a silver cup,	10 00
For the greatest product of Sea Island Cotton, a silver cup,	10 00
For the greatest product of Wheat, a silver cup,	10 00
For the greatest product of Rice, a silver cup,	10 00
For the greatest product of Potatoes, a silver cup,	10 00
For the best specimen of Silk Fabric, domestic, a silver cup,	10 00
For the best specimen of Woollen Fabric, domestic, a silver cup,	10 00
For the best specimen of Cotton Fabric, domestic, a silver cup,	10 00
For the best specimen of domestic Cotton Bagging, a silver cup,	10 00

These premiums are offered *only* to the successful competitors of local Societies, and where no local Societies exist, a competitor *may* send a certificate of the fact and exhibit.

All local Societies are requested to aid by authentic facts, the proper decision of the Agricultural Societies in the above awards.

JAMES B. DAVIS, Sec'y.

FOOD AND PASTURE FOR COWS.—In the same animal, says Johnston in his Lectures, the quantity of milk is known to be greatly influenced by the kind of food. This is best understood in the neighborhood of large towns, where the profit of the dairy-man is dependent upon the quantity, rather than upon the quality of his milk. Hence the value of highly succulent foods of the grass of irrigated meadows—of mashed and steamed food—of brewer's grains—of turneps, potatoes and beets—and of other similar vegetable productions, which contain much water, intimately mixed with nutritive matter, and thus tend both to aid in the production of milk, and to increase its quantity.

TURNEP SEED.

A SUPPLY of the following varieties of fresh TURNEP SEED just received, viz:

Yellow Sweedish or Ruta Baga, very fine for stock,
Large Globe Turnep,
" White Flat do.
" Hanover or White Ruta Baga do
" Norfolk do.
} Fine for table use.

For sale in quantities to suit purchasers, by
Aug. 30 18-tf WM. HAINES, JR.

GARDEN AND FIELD SEED.

A GENERAL assortment of fresh and genuine GARDEN and FIELD SEED, among which are the following:

Red and White Clover,
Blue and Green Grass,
Rye and Orchard do.,
Timothy and Herds do.,
Millet and Lucerne do.,
Seed Corn of every valuable variety,
Seed Wheat,
Buckwheat and Potato Oats,

Kept constantly on hand by the subscriber, all of which are offered for sale at very moderate prices. All orders, by mail or otherwise, executed with neatness and despatch.

VOL. II. AUGUSTA, GA., JUNE 12, 1844. No. 12.

DANA'S PRIZE ESSAY ON MANURES.

(Continued from page 82.)

SECTION SEVENTH.

Of the Circumstances which affect the Quality and Quantity of Animal Dung.

That we may reduce to some general principle, easily understood and easily remembered, the facts scattered up and down among the mass of writers and observers about the different quality of manure afforded by different animals, or the same animals at different times, let me, reader, request your company while I walk into a new department of your chemistry. You may not understand the reasons of this difference in manures; why, for instance, fattening cattle give stronger manure than working oxen, without going a little into the mode how animals are nourished. The whole may be stated in plain terms thus: All food serves two purposes. The first is to keep up the animal heat, and this part of food disappears in breathing or in forming fat; that is, after serving its purpose in the animal body, it goes off in the breath or sweat, or it forms fat. It is so essential to the action of breathing, that we will term it food for breathing, or the breathers. The second purpose answered by food is to build up, sustain, and renew the waste of the body.

Now all this is done from the blood. To form blood, animals must be supplied with its materials ready formed. They are ready formed in plants; and animals never do form the materials for making blood. We may, therefore, term this kind of food the blood-formers. We have then two classes of food, the breathers and the fat-formers, and the blood-formers. If we look to the nature of these different classes, we find that sugar, starch and gum, are breathers. Now there are three principles found in plants exactly and identically the same in chemical composition with white of egg, flesh, and curd of milk. Now these three principles exactly alike, whether derived from animals or from plants, are the only blood-formers. I shall not, reader, tax your attention further upon this subject, than to beg you to remember these important facts:—First, all food for breathing and forming fat, contains only these three elements —oxygen, hydrogen, and carbon. Secondly, all food for forming flesh and blood, in addition to these, contains nitrogen.

This is the gist of the whole matter, so far as relates to manure. Bear in mind as you go on with me, reader, this fact, that of all the food animals take, that alone which can form flesh and blood, contains nitrogen. The door is now open for explaining why age, sex, kind of employment, difference of food, difference of animal, can and do produce a marked difference in the value of different manures. And first, let us consider how the quantity is affected. This depends on the kind of food. The analysis of cattle dung, which has been given, is that of cows fed on hay, that is, herds-grass, red-top, &c., (or what is usually termed English hay,) potatoes and water: the cattle kept up the year round. An animal so treated, consumed in seven days—

Water,	611 lbs.
Potatoes,	87 "
Hay,	167 "

During this time she dropped clear dung 599 lbs., or very nearly a bushel of dung a day. Every attention was here paid to accuracy of measurement and weight. The annual amount of dung from one cow exceeds, by this account, that which is usually assigned. But, as it is a matter of some importance for the farmer to estimate what the produce of his stock may be in dung, the following statement, containing the results of a large establishment, will probably give that average.

At this establishment the cows were kept up the year round for their dung. It was collected for use from litter, and measured daily into large tubs of known capacity. The average number of cows kept was fifty-four for nine and a half years. During that time, they consumed of beets, meal, and pumpkins, brewery grains, cornstalks, turnips, potatoes, carrots and cabbages, 942,436 lbs., giving an average of green fodder, for each cow per year, 1,837 lbs. Average consumption of hay for each cow per annum, 8,164 lbs. The total dung for nine and a half years was 120,520 bushels, or per cow per annum, 235 bushels. This gives a daily consumption of green food, 5 lbs., and 22 lbs. of hay per cow, and two and a half pecks of dung per day, or about 56 lbs. per cow.

But according to some experiments made to determine how much the quality of the food affected the quantity of dung, it appears that the solid and fluid excrements partially dried, were, compared with the food, as follows:

In	Cattle. lbs.	Sheep. lbs.	Horses. lbs.
100 lbs rye straw gave d'g,	43	40	42
do hay do	44	42	45
do potatoes do	14	13	
do mangel-wurtzel do	6		
do green clover do	9½	8½	
do oats do		49	51
do rye do			53

My own experiments on this subject gave for 100 lbs. of hay and potatoes as above, estimating both as dry, or free from water of vegetation, 32.9 lbs. of dung; and this estimated as dry, is reduced to 5.6 lbs., or 26 lbs. of dry food gave 14 lbs. of dry dung. But as a general fact, we may say, that well-cured hay and the grains give one-half of their weight of dung and urine; potatoes, roots, and green grass, about one-tenth.

It will be easily understood why the quality of food should affect the quantity of dung. The more watery, the less in bulk is voided, because there is actually less substance taken. And as the animal requires this to form its flesh and blood and fat, and to keep up his breathing, so will he exhaust more completely his food. More going to support him, less is returned by the ordinary channels. So when much vegetable fibre exists, as in chopped straw and hay, then, as it goes but little way towards supporting breathing or forming blood, a greater bulk is rejected. In grains, on the contrary, which afford much of all that the animal requires, more is extracted and less voided.

The Quality of Dung.

It is affected first, by the season; second, by the age; third, by the sex; fourth, by the condition; fifth, by the mode of employment; sixth, by the nature of the beast; seventh, the kind of food.

1st. The season. It is because digestion is worse in summer than in winter, a general fact, that summer manure is best. And where cattle are summer-soiled, it is said the manure is worth double that from stall-fed winter cattle. I do not think much is to be attributed to the worse digestion in summer, but the cause of this great difference in value is to be found in the fact that soiled cattle generally get a large proportion of blood-forming food.

The wear and tear of their flesh is little, and hence, requiring little of their food to keep up their flesh, a greater portion goes off in dung, which thus becomes rich in ammonia. The green plants, rich in nitrogen, afford abundance for milk, which, being rich in all the elements of cream, should afford large returns of butter.

2d. Age. From the fact, that young and growing animals require not only food to form flesh and blood, to repair the incessant waste and change taking place in their bodies, as in older animals, but also a further supply to increase the bulk of their frame, it is evident that their food will be more completely exhausted of all its principles, and that also less will be returned as dung. All experience confirms this reasoning, and decides that the manure of young animals is ever the weakest and poorest.

3d. The sex. This is one of the most powerful of the causes which affect the strength of dung. From the remarks which have been already made, and which I trust, reader, are now fresh in your memory, of the important part acted by nitrogen in dung, it must be plain why sex should exercise such influence. 1st. In all food, as we have explained, that only which contains nitrogen, can form flesh and blood, or substances of similar constitution, that is, requiring a large proportion of nitrogen, as milk. Hence an animal with young, that is, a cow before calving, requires not only materials for its own repair, but to build up and perfect its young. Hence the food will be most completely exhausted of its nitrogen, and consequently the dung become proportionably weaker. 2d. The young having been formed, then milk is required for its sustenance. Milk contains a large proportion of nitrogenous or blood-forming elements, and so the cause which originally made the dung weak, continues to operate during all the time the animal is in milk. Sex, then, it is evident, affects materially the quality of the dung.

4th. The condition. If the animal is in good condition, and full grown, it requires only food enough to supply materials to renew its waste.

Hence the food (supposing that always in sufficient quantity) is less exhausted of its elements, than when the animal is in poor condition. In the last case, not only waste, but new materials must be supplied. If the animal is improving in *flesh*, (and here, reader, I would have you bear in mind the distinction between flesh and fat,) then the manure is always less strong, than when he is gaining fat. There is no manure so strong as that of fattening animals. An animal stall-fed, kept in proper warmth, requires but little of his breathing food to keep up his heat. All the starch, gum, sugar, &c., go to form fat. Having little use for his muscles or flesh, that suffers little waste, and the nitrogen which should go to form flesh, is voided in dung. If it is a she, no milk is given during this period, for a cow in milk fats not.

The dung, then, of fattening animals, contains more of all the elements of food for plants, than at any other period, and is peculiarly rich in nitrogen. I trust, reader, it is not so long since you have met the word ammonia, that you have

forgotten that its source and origin are due to this nitrogen. Now the source of this nitrogen is in the food, and as, during fattening, grain is supplied for its starch, &c., to make fat, and very little waste of the body taking place, the extra nitrogen of the blood-forming materials of grain, is nearly all voided in dung.

5th. The mode of employment. Your working beasts suffer great wear and tear of flesh and blood, bone and muscle, thews and sinews. Hence their daily food supplies only this daily waste; the food is very thoroughly exhausted, and of course the dung is weak. It derives its chief value from the excretions of those parts of the body which are voided as waste materials, among the excrements. There is a distinction to be noted here: excretions are the worn-out flesh and blood elements—excrements, the undigested and unused food: dung includes both excretions and excrements. Now the chief value of the dung of working cattle depends upon the excretions.

6th. The nature of the beast. If his coat is wool, he requires more sulphur and phosphorus, the natural yolk or sweat of his wool, more lime and ammonia, than does the hairy-coated animal. Hence sheep produce manure less rich in many of the elements of plants, than cattle; but as at the same time it contains a larger portion of nitrogen, and is very finely chewed, it runs quicker into fermentation. It is a hoter manure, quick to eat, quick to work, and is soon done.

7th. The kind of food. We have already spoken of this as affecting the quantity of dung. Its effects are no less marked on its quality. Now all that requires to be said on this subject, is to remind you, reader, of the two divisions of food, the fat-formers, and the flesh and blood-formers. It must be evident, that the more of this last the food contains, that is, the more nitrogenous is the food, the richer the dung.---Hence, grains of all sorts, peas, beans, &c., will always give a richer dung than fruits, as apples, &c. The more nitrogenous the hay, the richer the dung. Meadow cats-tail and rye grass are nearly six times stronger in ammonia than oat straw. Red clover is twice as rich in nitrogen as herds grass; wheat, barley, and rye straw, green carrots and potatoes contain only about one-third to one-fifth the ammonia of herds-grass, and turnips only about one-sixth. The quantity of ammonia contained in these different grasses and straws, shows at once the effect they must have in the compost heap. The kind of litter must have no small effect upon the value of manure. And while we are upon this subject, it may not be out of place to mention, that the kind of a green crop turned in, materially affects the value of the process. While the straws of the grain-bearing plants afford for every ton of green crop turned in, about three-quarters of a pound of ammonia, green corn-stalks and herds-grass, about five pounds of ammonia per ton; red clover affords about seventeen lbs. of ammonia per ton. The very great value of clover in enriching land is thus made evident. But to return to the quality of the dung, as affected by the food, it has been proved that animals fattening on oil cake, give manure in value double that of common stock. Here abundance of nitrogen is supplied where but very little is required, and consequently much is voided in dung.

The point to which we have arrived is a breathing place: the remarks which have been offered upon the action of salts, have prepared the way for our entering upon the next section —the second class of manures.

(To be Continued.)

INDUSTRY.

The following anecdote may give encouragement to the industrious:

Not long ago, a country gentleman had an estate of £200 a year, which he kept in his own hands until he found himself so much in debt, that, to satisfy his creditors, he was obliged to sell the half and let the remainder to a farmer for twenty years. Towards the expiration of the lease, the farmer coming one day to pay his rent, asked the gentleman whether he would sell his farm. "Why, will you buy it?" said the gentleman. "If you will part with it, and we can agree," replied the farmer. "That is exceedingly strange," said the gentleman; "pray tell me how it happens that, while I could not live upon twice as much land, for which I paid no rent, you are regularly paying me a hundred pounds a year for my farm, and are able, in a few years, to purchase it?" "The reason is plain," answered the farmer, "you sat still and said *go*—I got up and said *come*—you laid in bed and enjoyed your estate—I rose in the morning and minded my business."

OF THE AVERAGE QUANTITY OF BUTTER YIELDED BY MILK AND CREAM, AND OF THE YEARLY PRODUCE OF A COW.

I have already made you acquainted with some of those numerous circumstances by which the quality of milk is affected. These same circumstances will necessarily more or less affect the quantity of butter also, which a given weight or measure of milk can be made to yield.

Thus, in the King William's town dairy, (County Kerry,) the average quantity of milk and butter yielded by the Kerry and Ayrshire breeds respectively, was, in a whole year—

Ayrshire cow, 1328 quarts, of which nine and a half to nine and nine-tenths quarts, gave one pound of butter.

Kerry cow, 1264 quarts, of which from eight to eight and a fifth quarts, gave one pound of butter.

Showing, as I have before stated, that the small Kerry cow, upon the same pasture, will give a richer milk even than the Ayrshire.

In Holstein and Lunenburg again, it is considered, on an average, that 15 quarts of milk will yield one pound of butter. The milk in that country, therefore, must be very much poorer in butter.

The result of numerous trials, however, made upon the milk and cream of cows considered as good butter-givers, *in this country*, has established the following average relation between milk, cream and butter:

MILK.		CREAM.	BUTTER.
18 to 21 lbs. / 9 to 11 qts.	yield	4 lbs. / 2 qts*	or 1 lb.

The cow, therefore, that yields 3,000 quarts of milk, should produce, where butter is the principal object of the farmer, about 300 lbs. of butter, or 1 lb. a day, for 300 days in the year.

This is not a large daily produce, since some cows have been known to give, for a limited time, as much as two or even three pounds of butter in a single day. It is a large quantity, however, taken as the average of a lengthened period of time, and hence such cases as that of Mr. Cramp's cow, which, for four years, continuously yielded nearly a pound and a half of butter† every day, are naturally quoted as extraordinary.

In most districts, the average of the whole year is much less than a pound a day, even for ten months only. In Devon, for the first twenty weeks after calving, a good cow will yield 12 quarts a day, from which, by the method of scalding, a pound and a quarter of butter can be extracted.

In South Holland, a good cow will produce, during the summer months, about 76 lbs. of butter. In the high pastures of Scaria, in Switzerland, a cow will yield, during the ninety days of summer, about 40 lbs. of butter, or less than half a pound a day. In Holstein and Lunenburg, it is considered a fair return if a cow yields 100 lbs. of butter, and even in England, 160 to 180 lbs. is reckoned a fair annual produce for a cow, or from 8 to 9 ounces a day, for ten months in the year.

It is known that the butter produced in one district of the country differs often in quality from that produced in another, even though the same method of manufacture be adopted. In different seasons, also, the same farms will produce different qualities of butter; thus it is said that cows which are pastured yield the most pleasant butter in May, when the first green fodder comes in; that the finest flavored is given by cows fed upon spurrey (Sprengel); that it is generally the hardest when the animal lives upon dry food; and that the autumn butter is best for long keeping. These differences may all be ascribed to varieties or natural differences in the pasture or fodder upon which the cow is fed.* The constitution of the animal also is known to affect the quality of the butter—since there are some animals which, with the best food, will never give first-rate butter.

In all such cases as these, however, the quality of the butter is almost entirely dependant upon that of the milk from which it is made, so that whatever affects the quality of the milk, must influence also that of the butter prepared from it.

But from the same milk, and even from the same cream, by different modes of procedure, very different qualities of butter may be obtained. The mode of making or extracting butter, therefore, is highly worthy of attention. Let us consider a few of the more interesting circumstances under which different qualities of butter may be extracted from the same quality of milk or cream.

If the milk be collected in two or three successive portions, as it comes from the cow, the last drawn portion will be much richer than that which has been taken first. The cream yielded by it will also be richer, and of a finer and higher flavor. Whether, therefore, the butter be extracted directly from the whole milk, or from the cream, the butter obtained from the three successive portions will differ in quality almost as much as the several portions of milk themselves.

A practical application of this fact is made in some of the Highland counties of Scotland, and in other districts, where the calves are allowed to suck, or are fed with, the first half of the milk as it comes from the cow—the latter and richest half only being reserved for dairy purposes. This second milk is found to afford an exquisite butter.

In like manner, the first cream that rises upon any milk is always the richest, and gives the finest flavored butter. The after-creamings are not only poorer in butter, but yield it of a whiter color and of inferior quality.

This fact again is well understood, and has been long practically applied in the nighborhood of Epping, which is celebrated for the excellence of its butter. The cream of the first twenty-four hours is set aside and churned by itself. The second and third creams produce a pale, less pleasant butter, which always sells for an inferior price. Any admixture of the after-creamings causes a corresponding diminution in the value of the butter produced. To produce the most exquisite butter, the cream of the first eight hours only ought to be taken.

The rapidity with which cream rises to the surface, either naturally or when influenced by art, affects the quality of the cream, and consequently that of the butter made from it. In warm weather it rises more quickly than in cold, and more quickly still when the milk is heated, as in the preparation of clouted cream. The butter---Bohemian butter---obtained from such cream---from cream thus rapidly brought to the surface---may be expected to differ both in flavor, in consistency and in composition, from

*The quarts spoken of in this lecture are old wine quarts, of which five make an imperial gallon. A wine gallon of milk or cream weighs about 8 lbs. 4 oz., an imperial gallon about 10 lbs. 5 oz. About two imperial gallons, therefore, should yield a pound of butter.

†It gave, in four years, 2,132 lbs. of butter from 23,559 quarts of milk, or 16 quarts a day, of which 11 quarts gave a pound of butter.

*The influence of the food given in the stall, and of the plants eaten in the pasture, upon the color and flavor of the butter, is familiar to all practical men. The turnipy taste of the butter in winter—the garlick taste in summer, where the wild onion grows in the pastures—and the alleged effect of raw potatoes in winter, in giving a rich color to the butter, are common examples of this kind

that yielded by the cream of the same milk when allowed to rise in the usual manner.

For the production of the best butter, it is necessary that the cream should be sufficiently sour before it is put into the churn.---*Lectures on Agricult. Chemistry.*

From the N. E. Farmer.

CLOSE PLANTING OF CORN.

Mr. Breck:—I have sometimes thought that if farmers would communicate the results of unsuccessful experiments, through the medium of the agricultural journals, they would confer as great a benefit upon the public as they do by relating their successful experiments. In accordance with the above opinion, I will attempt to give the result of close planting of Indian corn the past season, though at the risk of being somewhat tedious.

In the spring of 1841, in consequence of the removal of an old fence, I had a strip of pasture land fifteen rods in length and two rods in width, added to a field. It was plowed up and planted with potatoes, and yielded a fair crop. In the spring of 1842, there were carted upon it four cart-loads of good stable manure, and deeply plowed; after laying a few days, it was harrowed, and four more loads of good compost manure, made of swamp muck, stable dung, lime, and ashes, were spread, and again plowed and harvested. About the 10th of May, drills were made by a kind of horse-rake, with the teeth just three feet apart; three kernels of the "brown corn" were dropped in the drills, at the distance of two feet; in a few days the corn came up, and grew rapidly; during the season, the ground was merely scraped over with the hoe three or four times, but no hills made. In October, when fully ripened, the corn was harvested, and produced over thirty bushels of large sound ears, and two bushels of small ears; and I think it would, when dry enough for the market, have shelled out 15 bushels, or at the rate of 75 bushels to the acre.

I intended to have sown it last spring, with oats and grass seed, but upon reading in the N. E. Farmer of March 22d, 1843, an account of a premium crop of corn raised in New York, by a Mr. Phelps, I was led to plant the patch again with corn, upon his plan. In his statement of the cultivation, &c., he says: "On the 23d of May, 1842, I plowed up one acre of green sward, for the purpose of planting it with corn. After plowing it once, I harrowed it well, lengthwise of the furrows. I then marked out the ground so that the rows and hills should stand precisely two feet apart either way. On the 25th of the same month, I planted it, and was careful to put precisely three kernels in each hill; when it was large enough, I hoed it, and continued to hoe it three different times. No other tool was used in the process of cultivation but the hoe, being very careful to keep the weeds and grass down as much as possible, and in hoeing, to leave the ground as near level as possible each time. I permitted the corn to stand until it was fit for harvesting, without cutting up or topping. Between the 10th and 15th of November, I began to husk and weigh the said corn. I found the aggregate weight from the said acre, in the ear, 13,286 lbs., of a good quality. About the first day of January, 1843, I thrashed out all the sound corn that grew on the said acre, and measured it, and found that it fully held out 60 lbs. to the bushel, and it produced me 122 bushels of good merchantable corn."

After reading the above statement, I thought I would try my small patch of ground again with corn, as before stated. I gave it the same preparation of manure, plowing, and harrowing, that it had the year previous: it was planted about the 12th of May, precisely as to the distance and seed, as Mr. Phelps says he planted his. It came up well, and on the first of July I thought I should get a real *crack* crop—something to brag about—notwithstanding several old grey-headed farmers told me that it was planted so thick, it would not amount to much except for fodder. In August, I began to think these old farmers knew a thing or two; for the bottom of the plants 12 or 18 inches, assumed a yellow color, and but few of the suckers tasseled out, but shrivelled up and dried; the ears that started, (two or three to every stalk,) stood perfectly erect, and did not "hang off" as they did the year before. However, when ripe, it was harvested, accurately measured, and instead of thirty bushels of ears, as I had the year previous, there was but eighteen bushels. As every thing was as favorable to the crop, except its close planting, I can conceive of no possible reason why it should not have been as good as the previous one, except the difference was caused by the close planting, which caused the corn to "draw up" spindling and weak.

From some experience of my own, and observation in the cultivation of corn by others, I think Mr. Phelps' method of culture is worthy of imitation, except the close planting. Several years ago, I planted a field of corn, and dropped two or three kernels extra in each hill, for fear the worms might take a part of them. At weeding or first hoeing, I pulled up a part of the surplus, and was surprised at the length of the root —not roots—as there was but one, the main root, which I frequently found had grown to the length of eighteen inches; and as the rows were three feet distant, I found in some instances that the roots from the opposite hills had met, and believing that all the roots sent out by plants are needed for their most perfect growth, and frequently having heard farmers complain of the injury done to their corn by the worms eating off the roots, I came to the conclusion that it made no difference with the corn whether its roots were cut off by a worm, a plow, or a cultivator. And knowing that neither a plow or cultivator could be run between the rows without cutting and lacerating the roots, I have never suffered any tool but the hoe in my cornfields since—although I have one of Prouty & Mears' horse-plows, a prime cultivator purchased at your store several years ago, and a steady horse to draw them. Since I have adopted this plan, I have had the satisfaction of knowing that my corn crops will compare, as to the quantity per acre, with any of the farmers in this vicinity.

Mr. P's plan of leaving the stalks uncut, no doubt added many bushels to his crop. For two years past, I have left an acre or two till harvesting, with the full belief that I gained more in the corn than I lost in the fodder, though I have my doubts about the fodder being very much less valuable than when cut in the usual way.

I have had the stalks and butts mowed away after husking, and given them a good sprinkling of salt, and my cattle have eaten them as freely and as clean as when cut and bundled up.

I think there can be no doubt that the quantity of corn is lessened to the amount of eight or ten bushels to the acre, by cutting the stalks, as is generally practiced. Careful and accurate experiments of the Hon. Wm. Clark, jr., of Northampton, and others, have put the question beyond dispute.

But a knowledge of the use and function of the leaf would, without an actual trial, satisfy any one of the fact. The moisture or water in the soil holding in solution a variety of salts, is taken up by the rootlets of plants, and by some mysterious power, propelled through the minute pores, or sap-vessels to the leaf, where, aided by solar light, (the rays of the sun,) a large amount of water escapes by evaporation, and the true sap is formed in the leaf, and by the vital powers, or action of the growing plant, the salts are retained to be assimilated, and assist in forming the complete and perfect plant, in all its varied parts and products. Now if the stalk of corn is cut off just above the ear, with all its long and broad green leaves, we violate the laws of nature and deprive the seeds of a portion of that food that would have been elaborated by the agency of the leaves.

The function of the leaves of plants, and the effect of the rays of the sun, in causing a greatly increased absorption of water by the roots, and consequently a corresponding ratio of moisture by the leaf, is very clearly and simply illustrated, by an experiment recommended last year by Professor Henslow, to the farmers of one of the counties in England. He directs that three tumblers, numbered 1, 2 and 3, be nearly filled with water, then oiled paper tied over the top of each tumbler, a hole made through the centre of each paper, and the stem of a leaf of a tree, (with the leaf attached,) be passed through the hole in the paper, so as to touch the water. No. 1, is to have an inverted tumbler put over it, and placed in the direct rays of the sun. No. 2 is to have an inverted tumbler put on, and placed in the light, but so as not to have the sun shine upon it; and the tumbler placed over No. 3, is to have a fold or two of paper wrapped round it, so as to exclude the light, and then placed over No. 3. The result will be as follows:—No. 1, placed in *sunshine*, will soon have the inside of the top tumbler coated over with moisture, which will be in such quantities as to trickle down the sides. No. 2 will have a very little moisture on one side—and No. 3 will have no water within. This little experiment proves that corn, potatoes and roots, should be planted at such distances as freely to admit the sun's rays, and that the amount of corn is lessened by cutting the stalks, and that the plucking of the leaves of mangold-wurtzel and turneps, for green fodder, must be attended with loss to the bulbs.

Every body knows that plants suffer by being in the shade, if the ground is ever so richly manured; and this experiment tells the why. In some parts of Russia, wheat is fit to harvest in six weeks from the time it is sown: their days contain 20 hours of broad sunlight, and that tells the wherefore.

But the leaves of plants have another important office to perform: they possess the power of absorbing the principal part of their carbon from the atmosphere in the form of carbonic acid, which is decomposed by the leaf, (with the aid of sunlight,) the oxygen is liberated, and the carbon retained, and forms about 44 per cent. of the solid or woody texture of plants. If the effect of the sun's rays upon growing plants were more generally understood, the plants in many of the gardens would not be left so thick. Many persons seem to go upon the principle that the more cucumber and melon vines there are in a hill, (and the hills two feet apart,) the more fruit they will obtain. I have frequently seen twelve or fifteen plants left in the hill, and the owner would about as soon have had one of his teeth extracted, as one of the plants pulled up.

L. B.

From the Albany Cultivator.

IMPROVEMENT OF CLAY SOILS.

Messrs. Editors—What method shall I take to reclaim worn-out land? soil, stubborn clay. Will leached ashes or lime effect a cure? If so, what proportion to the acre?

E. H. Northrup.

Shoreham, Vt., April 5, 1844.

The great trouble with a clay soil, is its tenacity. The compactness of its particles keeps, in wet weather, too much water on the surface; and in dry weather it 'bakes,' as we say—becomes so hard that it absorbs but little moisture, and cannot be penetrated by the roots of plants. Thus, on clay soils, vegetation is very likely to suffer in turns, both from an excess, and a deficiency of moisture.

To guard against these difficulties, the first object should be to break this obstinate tenacity by a thorough loosening. To keep the vegetable matters near the surface, where, especially on such soils, they are most effective in aiding the growth of plants, we would turn a rather thin furrow with the common plow, and follow with a sub-soil plow, running it as deep as the implement and the strength of the team would permit. This would allow the surplus water to pass readily into the earth—the roots of plants would easily find their way in search of food—while, in time of drouth, the exhalation of mois-

ture from below, as well as its absorption from the atmosphere, would be facilitated, and the growing crop would thus be protected from the evils of too much moisture at one time, and too little at another.

As to the kinds of manure to be used, we should endeavor to apply such as would tend to correct, as much as possible, the defects of the soil. From our own experience, we should not expect much benefit from the use of ashes—their effects are more favorable on sandy soils. We would try both lime and gypsum, and if their effects proved to be such as would render their application profitable, should use such quantities as seemed expedient. We should endeavor to induce the growth of clover, and if that crop could be made to flourish, it would be found a certain and great improver of the soil; and should gypsum operate well, a high degree of fertility might be gained by the use of that substance in connexion with clover. Animal manures of all kinds, if they can be had, should of course be applied, as they are valuable on soils; and if there was a chance to obtain saw-dust conveniently, and at small expense, we would use it liberally, having witnessed its effects in improving tenacious soils.

It is proper to observe, that, if draining should be necessary, that should be the first object of attention. The loosening of the soil, as above mentioned, will operate as a considerable drainage; but actual observation only can determine whether it will be sufficient.

From the Michigan Farmer.

THE PHYSICAL EDUCATION OF WOMAN.

BY GEO. W. CARHARTT.

Who can look abroad upon society, and compare those that are just entering upon the stage of action, with those who occupied it fifty years ago, and say that the present generation is not far inferior in beauty and physical strength.—Compare the wasp-like waist, the contracted lungs, the pale emaciated face, the irregular teeth, the sunken eyes—and, in fact, an almost complete prostration of all the powers, both mental and physical, (for it is a well established fact in science, that a given state of mind or body throws the other into a corresponding condition,) with the fair symmetrical form, the large, expanded and healthy lungs, the full, fair and animated face, the beautiful and regular teeth, the sparkling and lively eyes, the noble and healthy appearance, and the consequently strong mental and physical powers of the women of this country in by-gone days, and of other countries at the present time, and there will be found a vast difference in favor of the latter.

Investigation makes it evident that a large proportion of young ladies from the wealthier classes have the incipient stages of the curvature of the spine, one of the most certain and fruitful causes of future disease and decay. Medical men, who have made extensive inquiries, say that one of every five or six of the young women at boarding-schools, are affected in this way, while many other indications of disease and debility exist in cases where this particular evil cannot be detected. Why is this enfeebled state of the constitution ?—why does the primeval curse show itself more plainly now, than in former days?—why are the females of this country, at the present time, so much more subject to disease than those of former years? The reason is, their physical education is almost totally neglected, while they receive an improper and injudicious bodily training; hence the very design of their creation is frustrated. The organs of the body are hindered from performing their distinct and proper functions. And as soon as they are called to the responsibilities and trials of domestic life, their constitution fails, and their whole life becomes a burden: for no person can enjoy existence, when disease throws a dark cloud over the mind, and incapacitates her from the proper discharge of every duty.

There is not sufficient attention directed to that course of instruction and treatment which relates to the vigor and improvement of the bodily powers. The influence of the body on the mind is universally admitted. When the former is healthy and active, the latter becomes susceptible of so much the higher and more successful efforts: whereas a feeble constitution tends to the production of mental imbecility; materially lessens our usefulness; and throws a hue of sadness over all the scenes of life. Now our constitutions, our bodily powers, are very much at the mercy of those who control our physical education. A neglect on this particular is often followed by immediate misery. It is from such neglect that we are so often called to mourn over the premature extinction of brilliant genius; and such neglect has been too commonly practised in relation to female children. Many have become victims to it, throughout their whole lives—have suffered from perpetual irritability, pulmonary weakness, morbid sensibility, fickleness of purpose, inconsistency of conduct, and all the distressing agonies of nervous debility; and finally a premature death is the inevitable consequence. There is, doubtless, a constitutional difference in the sexes, and woman is not to be trained to the severe athletic exercises of men; but surely the former ought to have the benefit of all such becoming exercises as shall give them healthful bodies and firm nerves.

"Let the utmost attention," says the Rev. Mr Burrows, "now be paid to the physical education of females—not simply to their diet, temperance, and cleanliness, but to the proper treatment and training of the body. Let them have such physical recreation as shall be consistent with their delicacy of sex, and as shall serve to procure for them vigorous constitutions, and sound minds.—Strengthen their physical powers and you may give energy to their intellects, brilliant tints of beauty to their persons, animation to their spirits, and grace to their manners. Walking, riding, and gardening, in the open air, are practised by women of other nations to a far greater extent than by American females. Most English women in the wealthier classes are able to walk six or eight miles without oppressive fatigue, and when they visit this country, always express their surprise at the inactive habits of the American ladies. An English mother at thirty-five or forty is in the full bloom of perfected womanhood—as fresh, as fair, and healthy as her daughters. But where are the American mothers who can reach this period unfaded and unworn? If the daughters of this favored land would be fair, beautiful, healthy, and long-lived, they must exercise more in the air, and attend more to the improvement of their bodily powers. Exercise is not less necessary than food for the preservation of health. Those who labor are not only the most healthy, but generally the most happy part of mankind. Exercises in walking, riding, and gardening, are calculated to greatly improve the constitution, and give vigor and health to the whole system. There is nothing, perhaps, that tends more to improve the minds and bodies of females, than the cultivation of flowers: it awakens the highest and most refined feelings in the human mind. Here may be seen, by His beautiful works, the invisible God. A taste for flowers has always been regarded by the most learned mental philosophers as a symbol of a pure and virtuous mind; a high and refined state of moral feeling: it indicates a great susceptibility of improvement; and is the natural language of the most noble faculty in the mind of females."—What a beautiful occupation for the young ladies of Michigan to be engaged in: how happily may be spent a few leisure hours in the morning, when the glorious sun is just emerging from the eastern horizon, and all nature is clad in her beautiful livery! It is then that the mind is filled with hallowed emotions of adoration and praise. It is then that may be improved, to the very best advantage, both mind and body. Let strict attention be paid to the physical as well as mental education of the young women of this country, and we shall soon see health glowing in every countenance, beauty beaming from every eye; and they will reap as their reward, vigor and strength of mind and body—a happy and long life.

West Bloomfield, Mich., April, 1844.

From the Southern Planter.

WHITEWASH AND PAINT.

Mr. Editor—There is, in the domestic habits and management of the people in the Northern (I will not use the term "free" in contradistinction) and Southern States, nothing more striking than the difference in the appearance of the dwelling, out-houses, garden and other fences; especially all those about the homestead. In the North, all looks neat and fresh, with their houses and yards as if newly painted or whitewashed; their porticoes shaded and ornamented with the honey-suckle and multiflora, their little green plats before the door fringed with beds of roses, pinks and heart's-ease. How different in the South!—*in too many instances*, houses dark and dingy—windows broken—palings broken down—gardens demolished and lawns large enough for a New England plantation, rooted up by hogs, or grown up in weeds. I repeat, that though this state of things is not so universal as to make it characteristic of the large plantations of the middle and Southern States, this side of the Delaware—it yet exists to an extent which reflects any thing but credit on their proprietors. Surely those whose establishments exhibit this slovenly exterior, do not reflect that the passer-by who sees it, is apt to suspect that interior management is in some correspondence with external appearances. Let it not, however, be therefore inferred that the lady of the house is neglectful of what it is her province to look after—for what can she do, unassisted with means or materials? Let her have but a little help, a little encouragement in the way of kind words, and a small outlay—one hour in the week of "the hands on the place," with one or two dollars laid out in lime for whitewash, and a few flower seeds, a hammer, a gimblet, and a few pales and nails to patch up the enclosure, and what a difference it would make in the *little territory* reserved for the dominion of the housewife! How unjust, not to say cruel, to withhold all supplies, and yet make her bear the responsibility of the home department! The very thought of it always so fires me with indignation, that I could write a sermon if time and words were at command. But I only meant, without a word of comment, to send you, for preservation in the Planter, the accompanying recipe for making the best sort of substitute for paint—let it go to your readers, that no excuse may be left for not having their houses wear that outward appearance of cleanliness and attention to looks, which betokens pure morals and a cultivated taste within.

Washington, April 22, 1844. J. S. S.

"Brilliant Whitewash.—Many have heard of the brilliant stucco whitewash on the east of the President's house at Washington.—The following is a recipe for making it, with some additional improvements:

"Take half a bushel of nice unslaked lime, slake it with boiling water, covering it during the process to keep in the steam. Strain the liquid through a fine sieve or strainer, and add to it a peck of clean salt, previously well dissolved in warm water; three pounds of ground rice, boiled to a thin paste, and stirred in boiling hot: half a pound of powdered Spanish whiting, and a pound of clean glue, which has been previously dissolved by first soaking it well, and then hanging it over a slow fire, in a small kettle, within a large one filled with water. Add five gallons of hot water to the whole mixture; stir it well, and let it stand a few days covered from the dirt. It should be put on quite hot; for this purpose it can be kept in a kettle on a portable furnace. It is said that one pint of this mixture will cover a square yard upon the outside of a house, if properly applied. Brushes more or less small may be used, according to the neatnesss of the job required. It answers as well as oil paint for wood, brick, or stone, and is cheaper. It retains its brilliancy for many years.

"There is nothing of the kind that will compare with it, either for inside or outside walls. Coloring matter may be put in, and made of any shade you like. Spanish brown stirred in will make red or pink more or less deep, according to the quality. A delicate tinge of this is very pretty for inside walls. Fine pulverized common clay, well mixed with this Spanish brown before it is stirred into the mixture, makes a lilach color. Lampblack in moderate quantities makes a slate color, very suitable for the outside of buildings. Lampblack and Spanish brown mixed together produce a reddish stone color. Yellow ochre stirred in makes a yellow wash; but chrome goes further, and makes a color generally esteemed prettier. In all these cases, the darkness of the shade will of course be determined by the quantity of coloring matter used. It is difficult to make a rule, because tastes are very different; it would be best to try experiments on a shingle, and let it dry. I have been told that green must not be mixed with lime. The lime destroys the color, and the color has an effect on the whitewash, which makes it crack and peel.

"When walls have been badly smoked, and you wish to have them a clean white, it is well to squeeze indigo plentifully through a bag into the water you use, before it is stirred in the whole mixture.

"If a larger quantity than five gallons is wanted, the same proportions should be observed."

This, says the Editor of the Planter, is the third or fourth time that, by particular request, we have published the above recipe, which we have no doubt is an excellent one. But after all, we believe that white lead, especially at the low price at which it can be purchased at present, is the best and most economical pigment that can be used. At any rate, this is the experience of our Northern friends, who are proverbial for their economy and management. They paint every thing, except the ladies' cheeks, and that nature does for them in a manner to surpass even the purity of their beautiful cottages.

We intend to furnish directions for the mixing and laying on of white paint, so that every farmer may become his own painter. It is an operation much more simple than is generally imagined.

From the Southern Planter.

SMALL FARMS.

Mr. Editor—The great error committed by a very large majority of farmers is to cultivate too much land. The conduct pursued by a young farmer in my part of the country forcibly impressed this truth on my mind. He commenced farming on a tract of ordinary land, and influenced by the example of those around him, planted seventy thousand tobacco hills on slightly manured land; two hundred thousand corn hills on broom-straw and *hen-nest grass* land; he sowed one hundred bushels of wheat succeeding his corn crop; and in return for diligent cultivation and a continual hard press during the working season, he gathered eight or ten thousand pounds of tobacco, five hundred bushels corn, and two or three hundred bushels of wheat. This system was pursued by him for several years, with about the result above stated. Now, sir, how many farmers in Eastern Virginia are there who pursue the same course with similar results? Perhaps four-fifths, or may I not say nine-tenths? That is at least the proportion within my observation.

I will pursue the history of my farmer for their especial benefit. I have said he had a tract of ordinary, I might have said poor land; he had something else worth a little more than his land; he had a strong mind stored with a good stock of practical sense. He concluded there must be a better way of getting along than the one he was pursuing, and that he would try by doing less work, to make more money; a notion which I dare say the most of us are willing to adopt. He cut off nearly two-thirds of his crop, thirty thousand tobacco hills; next, he made less than one hundred thousand corn hills. He concentrated all the fertilizing means which he had expended before upon the larger surface, upon the more limited one, and at the close of the year, he gathered a little more crop than he had ever made before. Now this was encouraging, was it not? As he had expended a little more than one-third of the labor, he had nearly two-thirds of his time, to devote to some other, and he hoped more profitable employment; that time he employed in gathering materials to make manure. Adhering strictly to a small crop well manured and diligently cultivated, he has now the pleasure of gathering at the close of each year about double as much as he did in the beginning, besides having in tobacco an article worth as much again per hundred as formerly. He cultivates no land which will not well remunerate for the labor expended; and in addition to the ordinary means of manuring, he uses gypsum freely on his growing crop, and thought a year or two ago, when tobacco was higher than it is at present, that every barrel of gypsum applied to his growing tobacco, benefitted him fifty dollars.

I am here reminded of the remedy for flies in the tobacco plant bed. Is it generally known that one gallon of gypsum mixed with one gallon of corn meal, is sufficient to sprinkle over a plant bed of two hundred square yards, and if repeated as often as it disappears, answers the twofold purpose of preventing the ravages of the fly, and is the best manure for plants known?

I will conclude this communication, as it is already too long, by stating what would scarcely be credited, that the example of the farmer, above alluded to, is lost upon his neighbors.—Men are so wedded to old habits, that they pursue the old plan, of large fields, hard work, and small profits. The occupation of cultivating the soil is certainly a delightful one, but to look upon gullied hillsides, perpendicular plowing, and, as a necessary result, corn-stalks a little larger than broom-straws, is enough to cool down the most ardent zeal, and give it over to the management of the ignorant "drawers of water and hewers of wood."

Berkshire Hogs.—I do not know an individual who has mixed the Berkshire in his stock, or attempted to raise them exclusively, whose stock has not materially deteriorated. I know several who used to raise an abundance of pork and a surplus for sale, who now are dependant on Kentucky for their supply. I have never had one; my objection to both Berkshire and Nobone is one that would be laughed at by the Yankee; legs too short, and body too large: they require too much food, and have too little ability to get it. Give me something of the S. Carolina Sand Hill hog, a hearing ear, (at least in acorn time,) a light body, and long legs, then a good range, and I will ensure meat enough.

X. R. S.

Nottoway, April 25, 1844.

From the Southern Planter.

CATTLE DISTEMPER.

Mr. Editor—During the past year, there prevailed extensively in some portions of the upper country a disease among cattle no less fatal than common; during the prevalence of which, some of the finest cows and oxen to be found perhaps in the State, lost their lives. It commences generally very suddenly, without any signs of previous debility or disease, and runs its course in most cases in the short space of twenty-four hours. It seems to affect the head more than any other part of the system, producing great stupor and debility, perfect loss of appetite, and invariably *lock jaw*. The poor creature thus situated, continues to pine away, being unable to receive food into its stomach until it finally perishes for the want of nourishment. Perhaps there is no situation in which you can imagine an animal to be placed more calculated to excite our sympathies than the one under consideration. The disease was treated in various ways and by numerous remedies, when it first made its appearance, and all alike were equally inefficient, until finally the treatment we propose to offer in as few words as possible, was adopted. So soon as the disease makes its appearance, and before lock-jaw has taken place, a large dose of spirits of turpentine mixed with a table-spoon full of castor oil should be immediately administered in as much gruel as the animal can be made to swallow. The turpentine should amount to two or three table-spoon fulls. As soon as this has been accomplished, a large orifice should be made in the large vein of the neck, and two or three quarts of blood should be drawn; immediately after which, the spirits of turpentine should be rubbed on the neck and head. By following out this plan of treatment, and at the same time paying attention to the stall in which the animal is kept, the lives of many which otherwise would be lost, will be preserved.

Yours, &c,, L. B. A.

Richmond, Va., Jan. 12, 1844.

From the Maine Cultivator.

GREEN AND DRY WOOD.

A cord of wood whilst green, is said to contain 1.443 pounds of water, or one hogshead and two barrels. Let every farmer who hauls wood to market, remember that when he transports it green, he is carrying that weight and quantity of water on this load, which, if he had suffered his wood to remain after it was cut till it was suitably seasoned, he might save from the burden of his oxen or horses, or pile upon the top of it three-fourths of a cord of seasoned pine, and yet have no heavier load than the green cord alone weighed.

From the Farmer's Cabinet.

THINGS THAT I HAVE SEEN.

I have seen a farmer build a house so large and fine that the Sheriff turned him out of doors.

I have seen a young man sell a good farm, turn merchant, break and die in an insane hospital.

I have seen a farmer travel about so much, that there was nothing at home worth looking after.

I have seen a rich man's son begin where his father left off—wealthy; and end where his father begun—pennyless.

I have seen a worthy farmer's son idle away years of the prime of life in dissipation, and end his career in the poor-house.

I have seen the disobedience of a son "bring down the gray hairs of his father to the grave."

From the Southern Planter.

CLOVER, HERDS-GRASS, AND TIMOTHY.

Mr. Editor—I was much amused and gratified at the style in which you commented on the sayings and doings of the Farmers' Club of Henrico at their last meeting in October; and as clover formed the subject of discussion, I resolved at the time to give you the following hints as to the manner of curing it. After cutting, let it lie as long as possible without burning, and then put it up in the following manner: Cut for each cock three sticks, eight or nine feet long; stick the ends in the ground, about two feet apart, and tie the tops together with a rope of hay; then get a cedar log, and thrusting one end in between the foot of two of the upright sticks, let it remain in the base of the tripod; leave a limb upon the other end by which you may draw the log out when required; stack the clover, or other hay, against the sticks and over the log; then draw out the log; an opening will be left that will furnish free circulation for the air, and the clover will be very rapidly and perfectly cured. I have put up hay in this way whilst it was raining, and found it most excellently cured.

On the subject of herds-grass, permit me to ad

one word to what has been already written. Very poor and very dry land will bring it, if managed properly. It should be sown with oats or at the time of laying by your corn; turn in the product next year, and follow the plow with a roller; then harrow lightly, and sow timothy and roll again; then add a little top-dressing in the fall or early in the spring, and you will cut a good crop of grass. Our grasses do not penetrate deep enough to get the benefit of the soil on account of the dryness of the climate, and they, therefore, suffer much from the drought; but when the surface is inverted and the sod is kept unbroken, the grass puts up backwards, and the growth, even without manure, would astonish any one who saw it. If you are sceptical, just come out about the 10th of June, and you will then see for yourself. Let there be no mistake about the time the grass is plowed under; this should be done, if the grass is to be cut, immediately after the scythe; otherwise, when the heads are dry, and when the stalks are green, but ripe.

Timothy is a different thing from herds-grass; it is a complete bulb or root, of the shape of a wild onion. When it is cut, this strong root, if left to itself, sprouts promptly and sends out two or three shoots. If, in this sprouted, green and growing state, it is turned under so deep as to be beyond the influence of the sun and air, it must rot, of course: but if it is turned under only two or three inches deep, it comes through, and is greatly strengthened. I am now certain, that any land that will bring broomstraw, will bring good grass.

The farm I live on had not one thousand spires of good grass on it four years ago, and now, although no manure was ever put on a blade of grass, I cured 40,000 lbs. last year, notwithstanding I lost from five to ten thousand weight for want of hands to save it. This year I hope to reach 60,000 lbs. If the Farm Committee of the Agricultural Society will call on me from the 5th to the 20th of June, and will award a premium for "the most made from the least spent," I shall be happy to see them.

In my next, I will furnish you with a plan to enable poor farmers to make poor lands rich, which has forced itself on my attention, as it affords more, in my opinion, for the amount expended than any other plan I have seen recommended.

Yours, respectfully,

J. H. D. Lowndes.

Brookland, April, 1844.

From the American Agriculturist.

THE COW-PEA. PEACH, &c.

The Cow-Pea as a Fertilizer, its Culture and value for Fodder.—I am convinced, from the limited experiments I have as yet had it in my power to make, that the cow-pea is one of the very best, and certainly the cheapest fertilizer that we can employ in the South. By some it is looked upon as an exhausting crop, nor is it to be wondered at that it should be so. Land that is tolerably poor is of preterence selected, as there the pea goes less to vine, and pods more abundantly; and just before frost, the entire plant, root and all, is pulled up and cured for fodder! I was forced to do this once, but will not try it again. Even then, however, the land was somewhat improved, as the leaves had all dropped before I felt forced to skin so deeply, by the prospect of being short of fodder, and the ground was so effectually shaded all summer.

I will now suggest some experiments, which, if I live another year or two, I shall try. I am unfortunately situated like too many of my brother planters, and have little leisure for anything but cotton-making. Where a planter aims at producing, to as great a certainty as possible, as much cotton as his hands can pick, up to Christmas day, he has no time for other occupation. If we could be satisfied with as much as could be saved before the 1st December, something could be done in the way of improvement. The making of sufficient manure for a large plantation, and hauling it out when made, seem heavy tasks, and they are so. Yet it would certainly be just as easy to make and apply three times as much manure on a plantation working thirty hands, with of course teams in proportion, as on one of ten hands. The waste of valuable manure on plantations is very great, and it will be many years before much improvement is effected.

I propose to select ten acres of poor land, which I will have well plowed, and as early as 1st to 15th March planted in cow-peas sufficiently close to give a good and early covering to the ground. Peas planted early produce more vine and fewer seed than when planted late. So soon as they begin to blossom freely, I shall have them turned completely under, and another crop of peas immediately planted. The second crop I intend shall stand to ripen, when I will turn hogs upon them, but no cattle, so that the leaves and vines will be almost all returned to the soil. One half of the lot I will have turned over deeply in the fall, the other half in the spring, planting one half of each five acres in cotton, and the other half in corn. It was my intention to experiment in this way this season, but circumstances render it impossible to any extent. That such a course will do more for our land here than the turning under of a crop of clover will in the north, is obvious. The quantity of vegetable matter on the ground, other things being equal, is vastly greater—I should say some three fold; the roots are few, one long tap-root only, with a few slight fibres; the vines and leaves large and extremely succulent, completely shading and protecting the soil from the sun; and the plant is of but a very few weeks growth. The cow-pea requires little or no culture, which is in favor of its value for this purpose—a bull-tongue plow run along each side of the row will suffice, though even this may be dispensed with. I would not wish to have it thought that I am advancing what I suppose to be a new idea, in advocating the value of this plant for this purpose. It has already been *discussed* in all its bearings, but has been *but little tried*. My object is to induce a few such trials as that I have proposed. If our agricultural societies would give prizes for the best conducted and most successful experiments of the kind, they would do infinitely more good than by the course they at present pursue.

As a fodder-making crop, the cow-pea is invaluable. It is, like clover, difficult to save, but when saved, of greater value. This I have tested. I had a plan for gathering and saving pea-fodder, suggested to me the other day, that is well suited to the cotton plantation, and which I shall practice when the vines are sufficiently matured, and plentifully covered with their long, well-filled pods; namely, run a heavy, iron-toothed, two-horse harrow over them, and as the harrow becomes loaded with vines, lift it up and pass on. By this means, the vines are rapidly gathered into piles, with a little dirt perhaps among them, which will shake out in curing. They are then put up in rail pens in the usual way. You must bear in mind, when you see such a mode recommended for harvesting a crop, that to *cradle* the cow-pea is impossible; to cut them with scythe or sickle, a slow, troublesome business; and that the most convenient and common practice is to pull them up, root and all, by hand. Their growth resembles that of none of your northern peas, but is rather that of a gigantic clover, with vines of any length under say 8 to 15 feet. The pods are very numerous, generally in pairs, and contain each some 15 to 25 peas, which afford most excellent and nutritious food for man and beast. One of the most extensive and experienced planters in the adjoining county of Jefferson, killed upward of 700 head of hogs for the supply of his own family, (and had not enough then,) which were fattened entirely in the pea-fields.

Peach and Fig Orchard.—I have just completed the planting of a small peach and fig orchard here, embracing 350 trees of the former, and 50 of the latter; and three hands, besides what assistance I gave myself, have been busily occupied three days in doing it; two more following up and giving each tree a couple of buckets of water. I would certainly prefer that they had been planted last fall, but it rained so incessantly, that it was impracticable. The peach-trees are one year's growth from the kernel, and will be budded where they stand this summer. I would rather have had the kernel dropped where the trees now stand; but that, too, was impracticable. I shall cultivate the ground this season in Irish potatoes and early corn, both followed by peas and sweet potatoes; some of it will be in pindars, and some poor spots in peas, to be turned under green, followed by peas again, turned under. Each tree shall receive, during the summer, a good barrowful of pure marl, placed immediately around it.

The Yellows.—From what I see in various papers, the disease called yellows is rapidly spreading among the peach-trees all around you. Opinions as to its nature and origin seem various enough, but I see no plausible method of cure or prevention. From what I have seen of it, I have no doubt of its being a disease *sui generis*, and if occasinned by an insect, certainly not by the *Ægeria Exitiosa*. So far as I can learn, the yellows is altogether or nearly unknown here, while the ægeria is sufficiently troublesome. The peach-tree dies, with us, only of old age and neglect. Such extravagant crops I have never seen anywhere—so heavy that the trees are seriously injured thereby. This is the worst kind of neglect. The fruit, when so very numerous, should be thinned out when as large as pigeon's eggs, both to improve the quality and to favor the tree. You will find a short article on "the causes of decay in peach-trees, and their prevention," in a little almanac I prepared in 1842, which contains the results of my experience and observation on this subject.*

Some one suggested at a recent meeting of your excellent New York Farmer's Club, that young trees produced from Mexican peach-stones, were free from yellows. I have no doubt that those from this part of the country would be equally so; and if it would be any object to some of your friends, sufferers from this disease, (and subscribers to at least two agricultural papers—you know my rule!) to try whether or no, I should take pleasure in saving some pits for them this summer, as we have so far this season, the prospect of a full crop of every kind of fruit, which, however, *might be* blasted by a late frost. Peach, plum, pear, and fig-trees, are all in full bloom, and have been for two weeks past. It is rare, indeed, that our peach-trees *repudiate the debt* they owe the careful cultivator; so that even your fastidious New Yorkers need not mistrust them, though they do come from Mississippi!

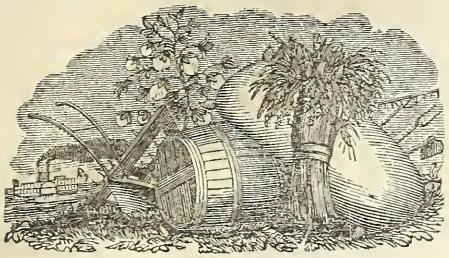
Migration of Birds.—They must have had a moderate, open winter north, and northwest of us, to what they had during that of '42 and '43, if we may judge from the movements or migration of the birds, a subject which is deserving of more notice from farmers, and of record in farming papers, than it receives. During the winter preceding this, the open commons, pastures, and cotton-fields, were frequented, for several weeks, by large flocks of a plover, which I am inclined to think is the golden-plover, (*charadrius pluvialis* of Wilson,) though differing slightly in its markings and size. They afford capital eating, as I proved to the extent of sundry dozens. The same birds are to be found in vast numbers on the prairies of Illinois, during an open winter or early spring, and I presume were driven thus far South by the severity of that season there. The robin (*T. Migratorius*) and the cedar-bird (*Ampelis Americana*) were also unusally numerous. This past winter, neither robins nor plovers have been seen, and but very few cedar-birds. The sand-hill crane is also but poorly represented this season.

Thomas Affleck.

Ingleside, Adams Co., Miss., March 5, 1844.

---

*Note.—From the date of this letter, our readers will see, that Mr. Affleck, when he wrote, could not have yet seen the able article on the Peach-Tree, by S. S., which appeared in our February and March numbers for this volume. In that, the yellows is attributed to the aphides or plant-lice.—Ed.



WEDNESDAY, JUNE 12, 1844.

☞The absence of the editor for some days, and other pressing engagements, must be our apology for the usual editorial comments, notices, &c.

GREAT CROPS.—Gov. Hill states, in the Monthly Visitor, that there were raised last year, on an island in Winnipisseogee lake, 66½ bushels of fine spring wheat to the acre—the same land having given, the year before, 137 bushels of shelled corn. The farmers of that region, we should suppose, can have no great desire to emigrate West.

WORMS ON CABBAGE.---These pests of the garden may be destroyed by taking off one of the large lower leaves of the cabbage, about sundown, and laying it on the top of the plant, "backside down." Take it off early in the morning, and the whole or a large part of the worms of that cabbage will be on it, and may be destroyed at pleasure. So says W. Chandler, in the Tennessee Agriculturist.

☞Immediately after a cold night, or when frost is discovered on plants, have them well watered with spring or pump water. The watering must be done before sunrise, otherwise the plants will suffer or be entirely destroyed.

HARVEST DRINK.---To 10 gallons of water add half a gallon of molassess, a quart of vinegar, and 4 oz. of ginger. Let the water be fresh from the spring or well, stir the whole well together, and you will have a most refreshing harvest beverage.

SALTING HORSES.

A curious fact is mentioned in Parker's Treatise on Salt:

"A person who kept sixteen farming horses, made the following experiment with seven of them which had been accustomed to eat salt with their food: lumps of rock salt were laid in their mangers, and these lumps, previously weighed, were examined weekly to ascertain what quantity had been consumed, and it was repeatedly found that, whenever these horses were fed on hay and corn, they consumed only about two and a half or three ounces per day, but that when they were fed with new hay, they took six ounces per day."

This should convince us of the expedience of permitting our cattle the free use of salt at all times; and it cannot be given in so convenient a form as rock salt, it being much more palatable than the other in a refined state, and by far cheaper. A good lump should always be kept in a box, by the side of the animal, without fear that it will ever be taken in excess.

☞Take the agricultural paper *published in our own State.* A good pig will pay for it.

ACRICULTURAL MEETING.

MONROE, GA., June 4th, 1844.

At a meeting of a portion of the citizens of Walton county, this day held in the court house, for the purpose of forming an Agricultural Society, John Scott was called to the Chair, and G. T. Symmes requested to act as Secretary.

After a short explanation of the organization of such Society, by Williams Rutherford, Jr., and Col. C. D. Davis, on motion of Mr. Rutherford, the constitution of the Hancock Club was read, and unanimously adopted. After which the following gentlemen were chosen officers of said Club, viz:

Williams Rutherford, Jr., President.
John Scott, 1st Vice "
Thos. W. Craven, 2d Vice "
John P. Snow, 3d " "
G. T. Symmes, Recording Sec'y.
Jas. Jackson, Correspond'g "
G. W. H. Murrell, Treasurer.

On motion, the proceedings were requested to be sent to the Editors of the Southern Cultivator for publication.

JOHN SCOTT, Chairman.
G. T. SYMMES, Recording Sec'y.

For the Southern Cultivator.

MESSRS. EDITORS:—As a reader of your paper, suffer me to make some inquiries of you, or some of your well-informed correspondents:

1st. What preparation of the soil is necessary, the time when, and the quantity of seed to be sown per acre, of orchard grass and clover respectively? In regard to the latter, I believe it is usual, or at least frequent, to sow with oats or other small grain. This, I suppose, is to protect it from the sun. If this is done, are the clover and oats to be sown together? I think it has been recommended to blend several, or at least two kinds of seeds together—which are preferable?

2d. In regard to grass for yards, lawns, &c.: which is most preferable where it is not to be cropped, and when to be sown? Should the seeds be ploughed in, or the ground previously broken up, and then harrowed in? Would it be best to manure upon a soil a little rolling, rather poor and somewhat stony? (I mean for the yard.)

3d. I have seen charcoal recommended as a manure for wheat, and I believe it is generally advised to apply manure for this grain to the previous crop. Can this be done in this instance, or may it not be applied at the time of sowing? In my section of country, it is usually (if not universally) the practice to sow wheat on ground which has just grown a crop of corn. How and when shall the ground, under these circumstances, be manured?

4th. Nearly all the northern agricultural papers speak of and recommend plaster, (gypsum I suppose) for various applications. What is this substance? Where does it exist; and, in its absence, what shall supply its place? It would seem to be a very common article at the north, but I am not aware of its existence in this section of the country. Does not lime constitute its basis?

My communication will not add to the *information* of yourselves, Messrs. Editors, nor of your readers; yet, *an answer* to the several questions proposed, may relieve some other agricultural novice beside myself, and hence oblige him as well as yours, truly, M. H. S.

Halifax Co., N. C., May 27th.

☞We hope some of our correspondents who have made the necessary experiments in these matters, will respond to the enquiries of M. H. S.—ED. CULT.

From the Southern Planter.

EMIGRATION.

We make the following extract from a letter from Dr. Philips, Editor of the South-Western Farmer, Mississippi, to his brother Editor of the American Agriculturist. We do not hesitate in expressing the opinion, that this estimate of the disadvantages of emigration, is in accordance with the experience of nine-tenths of the emigrants to other States: the most of whom have sought, in a change of habitation, a relief from difficulties, which they were too loath to ascribe to the effects of an ill-regulated life:

"PLEASURES AND ADVANTAGES OF REMAINING AT HOME.—Let any man 'cypher' up the cost of moving—the cost of land—the cost of building—the cost of clearing—to say nothing of the deprivations in a country where farms are to open—the loss of dear associates—our school-mates—and the time required to prepare for making money, and I venture on it, no sane man will move. I want to see many from those old countries here: not that, Indian-like, I wish them to suffer because I have, but that I want a thicker-settled country, and more demand for land. Yet with all this, I would recommend them to improve at home where they now are; husband their resources; study the economy of manures, improved agricultural implements, stock, seeds, the best rotation, and management of crops.

"Would that man merit aught but opprobrium, who would urge his fellows to sever every tender tie that binds him to 'Home, sweet home;' to even the 'old oaken bucket;' to the soil; to his associates and relatives, for the purpose of getting richer land, which, when cleared, and cultivated as is now done, will cause the young flock to wander again—and in reality, only serve to support one generation? I say nay, and therefore urge it on our brother farmer C. McD., as on all others in that good old State, to make it a part of their regular business to save, gather and make manure; they will find that three years of labor, with the cost and loss of moving, will give them such lands, that they will cling to the 'old South State,' even if they live in the 'Pedee country—God bless you.'"

☞The humble man is like a good tree—the fuller of fruit the branches are, the lower they bend.

☞Farmers, look well to your crops—let not the grass and weeds flourish, while your corn crops are diminishing.

☞I O U are the vowels which create more disagreeable sensations in the minds of honest men, than all the rest of the alphabet put together.

☞An honest farmer might as well expect to draw blood from a turnep, as to seek happiness at home or elsewhere, while *in debt* to a large amount.

From the Albany Cultivator.

IMPROVEMENT OF FARM STOCK.

Messrs. Editors—The improvement of farm stock can hardly be too frequently brought before the mind of the agriculturist, and of all who feel any interest in the prosperity of the country. No individual of any observation, whose attention has been drawn to this subject, and who has had an opportunity of critically examining the quality and character of the stock reared by a vast majority of farmers, can fail to be forcibly impressed with its importance to the nation, as a permanent, certain, and reliable means of largely increasing the aggregate wealth and resources of the whole country.

It is believed that this subject may appropriately engage the attention of the merchant, the manufacturer, the statesman and the patriot, as well as the farmer, when it is considered that agriculture is the foundation and the main source of national wealth, as it puts in motion, and imparts life and energy to all other branches of national industry. Let the agricultural products of the country fail for a single year, and what effect would it produce on all other interests? The ships of the merchant would be found moored and decaying at his wharf; the manufactories would cease to operate; our noble canals would then indeed become a "*solitary wilderness,*" and every branch of industry would become paralyzed.

If, then, such vast interests are so intimately connected with a well-regulated, intelligent and prosperous husbandry, it may well be inquired whether improvement in farm stock, which is one of the principal items of the farmer's wealth, is not important, and intimately connected with the general interests and prosperity of the country? More particularly is it so to the farmer, and improvement must principally depend on his well-directed and persevering exertions. Each farmer should put the question directly to himself—"Have I in my possession neat cattle which possess the greatest combination of excellence, which are the most profitable for the dairy, which will mature early, and when no longer wanted for dairy purposes, will put on flesh with the least expense in feeding for the butcher? Have I the best sheep for fleece and carcass—the best breed of swine, those of quick growth and approved fattening qualities?" And if, on investigation, he becomes satisfied he is deficient in one or all of this description of animals, his own interest should at once stimulate him to spare no pains to procure such, no matter if it be at extra-exertion, and a reasonable additional expense; for what is an outlay of a few hundred dollars compared with the accumulated profits one may reasonably expect to derive in the period of a few years. Besides, there are other considerations of great interest that should not be lost sight of. It is well known that a great proportion of the labor and expense of the farmer is bestowed upon his grain and root crops; and when those are well secured, it becomes a matter of interest to decide how they shall be disposed of to the most profit. Perhaps a great proportion of farmers decide on feeding them to their stock to fatten them for their own consumption and for the butcher. If stock can be raised, which will consume one-third or one-quarter less food than the ordinary or unimproved stock of the country, how important is it he should rear such stock?

This is no ordinary subject; and there can scarcely be any just reason why it should not as deeply interest the agriculturists and arouse them to action, as does the improvement of our home fabrics interest and engage the attention, zeal and persevering energies of the manufacturers. Why do those who are engaged in this branch of industry devote so much time and means in perfecting labor-saving machines? Why so much solicitude in regard to a discriminating protective tariff, and why do they invoke the aid and influence of the agriculturist, whenever there is a proposition to modify the tariff in the slightest degree, and why is an appeal made to sustain this interest through pamphlets, handbills, and in the columns of almost every newspaper in the country, calling upon all classes to sustain this interest? It is simply because they have the discernment to see that their interests are involved in this question, and that their prosperity is in jeopardy. This is a right spirit, when so restrained and directed as not to infringe upon or injure other equally important interests. Now, until something like the same spirit which so extensively pervades the minds of those who are engaged in manufacturing, is infused into the minds of the practical agriculturists, improvement in farm stock will be of slow growth, and no permanent beneficial results can reasonably be expected. The agriculturists of England understood well their true interests in this branch of husbandry, and they have extensively encouraged the breeding of superior stock, and for the last fifty years or more, have, by unwearied attention and perseverance, brought up their stock to a point of perfection which is unrivalled by that of any other country, and which has largely contributed to swell the wealth of that nation. This improvement has increased their commerce; their stock has attracted the attention of other countries, and exportations to a considerable extent are annually made, and at high prices. The writer of this article recently wrote to a distinguished breeder of England to be informed what he would charge for one of his best Durham heifers to be shipped this spring, and he replied that his price for one about two years old, would be two hundred, and for another one about three years old, would be three hundred guineas. This fact is stated merely to show the value they put upon improved stock.

There have been imported into this country a variety of the very best improved breeds of animals from England, at considerable risk and expense, to propagate and to improve our native stock. Thus a foundation has been laid, which, if duly appreciated by those most deeply interested, very favorable results may justly be expected. Who has attended our State and County Fairs for three years past, and has not had his admiration excited by the fine display of the noble Durhams, Herefords and Devon cattle, as well as the fine sheep and swine which have graced their exhibitions and done so much honor to their owners. This stock has justly elicited the approval of the several viewing committees appointed as judges, and they have very properly awarded them the highest premiums of the several societies; and it is exceedingly to be regretted that the matter should rest here. If the owners of those improved breeds of animals should have one or more which they could dispose of, to those whose interest it is to purchase them, if any offer is made for them it would hardly be sufficient to pay the freight on a single animal across the Atlantic. Is this a right spirit? Will such apathy and disregard of interest, on a subject which is so intimately connected with the great agricultural interests, promote improvement, or will it not produce a decidedly contrary effect, and discourage those who now take an interest in the subject, and who are willing to devote some time and their resources, to carry forward improvement? It is to be hoped that a better spirit will soon prevail, and that that attention will be given to the subject, which, from its importance, it is justly entitled to. The Fair of the New York State Agricultural Society is to be held at Poughkeepsie in September. The location selected for it is a good one, and affords great facilities for transporting stock. The premiums offered on stock are of sufficient magnitude to induce owners of good stock to exhibit it, and doubtless there will be a display of fine improved animals which will far surpass that of any other exhibition which has ever occurred in this country. The concourse of people which will there assemble, will doubtless be very great, not only from this but from other States, and if a right spirit is evinced by those whose interest it is to possess good stock, a new impulse will be given to this branch of husbandry which may, in a few years, produce great improvement, and eventually raise the quality of our stock to a point of perfection equal to that of England. These thoughts are thrown out in the hope that the subject may engage the attention of others previous to the Fair in September. C.

Rensselær County, April 25, 1844.

Sheep in the British Isles.—These exceed thirty millions in number, which is ten millions more than we have in the United States; and yet how small their territory compared with ours.

TURNEP SEED.

A SUPPLY of the following varieties of fresh TURNEP SEED just received, viz:

Yellow Sweedish or Ruta Baga, very fine for stock,
Large Globe Turnep, } Fine
" White Flat do. } for
" Hanover or White Ruta Baga do } table
" Norfolk do. } use.

For sale in quantities to suit purchasers, by
Aug. 30 18-tf WM. HAINES, Jr.

GARDEN AND FIELD SEED.

A GENERAL assortment of fresh and genuine GARDEN and FIELD SEED, among which are the following:

Red and White Clover,
Blue and Green Grass,
Rye and Orchard do.,
Timothy and Herds do.,
Millet and Lucerne do.,
Seed Corn of every valuable variety,
Seed Wheat,
Buckwheat and Potato Oats,

Kept constantly on hand by the subscriber, all of which are offered for sale at very moderate prices. All orders, by mail or otherwise, executed with neatness and despatch.

VOL. II. AUGUSTA, GA., JUNE 26, 1844. No. 13.

Communications.

For the Southern Cultivator.

MR. EDITOR—By referring to the last number of the Columbia (S.C.) Carolinian, you will perceive that the subject of overseers is undergoing an able and thorough discussion. No question connected with Southern Agriculture is more interesting in a pecuniary view, nor more important to the rapid improvement of the science: and, singular as it may appear, it is true, that, in the astonishing progress which has been made of recent years, in the analysis and adaptation of manures, in the mode of ameliorating lands, and of cultivating the staples, little or nothing has been said or done, in relation to the practical operator, in the application of these changes.

The general practice, heretofore, has been to select an overseer, with regard, simply, to experience of planting, and to sobriety: and, considering the frequent and often long-continued absence of the employer, the entire control of the business, which it has been usual to intrust to the agent, and the universal custom of looking only to the result of the crop as the sole test of good management, these qualities, superadded to industry and energy, would perhaps have been enough. Relying fully upon the judgment and experience of the overseer, this functionary is permitted to direct the mode of preparing and manuring the land, the period and manner of planting, the extent of tasks, with the inequalities in them, applicable to difference of sex and age, of health and strength of the laborers, and the vital part of cultivating the crop. Thus, master of his own actions, and responsible really to no one, he rides over the fields, and inspects the work and the stock, at his option; experiments with implements and with soils at pleasure, and always fruitlessly, since he is unaided by the knowledge of any scientific principle; and, knowing that neither his situation nor his reputation will be compromised while his crop can compare with those of his neighbors, the better paid of them, sometimes indolently visits his charge in a carriage,* and often keeps his dogs and his boat, and indulges in the agreeable pastimes of the chase and the rod. Happy lot is that of overseer—for a man without education generally, and born to labor. He is well paid for playing the luxurious part of gentleman, and possesses, for the time, the plantation in his care, with all its means of contributing to his comfort and pleasure.

But a revolution is at hand. The system is not to be modified, but to be reversed. Planters, thus far,—at least, it is generally so with us—have enjoyed the bounties of virgin soil, of large products from them, almost spontaneously, and of fair prices. Receiving a liberal return from their investments, and from trifling labor in cultivation, and living in a country where the standard of wealth is low, and the means of subsistence abundant and cheap, and extravagant luxuries are almost unknown, they have been able to give good wages to their employees, and furnish them with every requisite comfort,—and beeninduced, by their easy independence, to exact little from them, beyond a loose attendance on their places, and to pay little attention themselves to their own affairs, further than to pocket the proceeds of the crop, and replenish the plantation deficiencies. The times, however, have now changed. Our lands are becoming worn, and it will be necessary to supply them periodically, with those essential ingredients that are periodically abstracted. They must be properly fallowed and rotated, and judiciously and carefully tilled. Our negroes, if possible, must be more gently worked. Amid the multiplying blessings of civilization, and the vastly improved system of agriculture we are striving to introduce, it is our duty to convey some of their ameliorating effects to the operative. Competition in the product of our great staple is increasing, too: the growth of it is extending in India,—and, from late accounts. they mean not only to surpass, in quality, our Orleans and Mobile Cotton, our Georgia's and Santee's, but to rival also our long staple. Should Texas be immediately annexed, it will open a wide field for its cultivation; and, from the vast extent of its fertile and inexhaustible soil, and its benificent clime, will probably one day monopolize its culture. And, if the Union is deferred, it will only defer our doom as *extensive* cotton growers. Our Southwestern brethren are investing more largely each year, in its production, and with superior advantages of climate and soil. It is enough to cite these, without alluding to less enterprising and less favored competitors, like the Brazils and the Eastern Islands.

And what is more alarming still, is the fact, that production is at last outstripping consumption. In 1834, we produced little over a million of bags: in 1844, with the continuance of a good season, we cannot calculate on less than three millions, while the markets of the world are glutted beyond example, and the raw material about as low-priced as it has ever been, with the prospect of sinking still lower; and this, too, under a crop of only two millions of bags. The hopes entertained of the Chinese market, are all fallacious. No great benefit could accrue to us immediately, from the opening of all their ports. They are too poor to buy: they are almost as destitute as the Irish: they have mainly their great staple of tea to exchange, and the consumption of it is insignificant, compared with what it should be, to aid us materially in the disposal of our cotton. If a prohibitory tariff were imposed upon coffee, and tea were to become the universal beverage, it would not vary the result to the required point. The theory so fondly cherished by many, that the increase of negroes will not be in proportion to the increase of consumption—that increased production is dependent upon the increased force to create it, and that ere long consumption must exceed it by a large proportion, is equally ideal. There are nearly three millions of negroes in the Southern States: nearly two millions of them are workers. Concentrate these, as ere long under valuable returns and active competition they would be, in the best cotton growing region. Suppose a yield of 2500 lbs. neat cotton, or 5 bags to the hand, and you will have nearly ten millions of bags. These negroes, if well fed and clothed, and not overtasked, (and the mass of them are so treated, and their condition in these respects is yearly improving,) it is asserted, by a late writer, will double their numbers in 25 years. The crop, at the end of that period, (without considering the changes to be made, in the meantime, in the system of planting, and which may increase largely the product to the hand,) would be nearly 20 millions of bags, or 10,000 millions pounds, and enough to clothe the whole human family, even if it should double itself likewise; which, of course, it is far from doing, or ever having done, in that period. The notion is fanciful, and can only be indulged by those who are neither calculating nor practical.

No, we must abandon the well-spun theories, which are seducing us into dreams of prosperity and security; and yield at once to the conviction, that it is necessary to accommodate ourselves to our new circumstances. We must be prepared to meet the crisis when it comes. We must begin at once the practice of frugality and economy. We must combine farming with planting; produce all that is practicable at home, and no longer permit ourselves to be furnished with any of the means of support or of labor from beyond the mountains. But, first of all, we must turn our undivided attention to our own business; study fully the theory of our pursuit, and practically apply its principles. We must test the discoveries and improvements that are constantly being made; and, by original experiments, add to the knowledge of the country. And, to do all this effectually, we must be aided by industrious, energetic and intelligent overseers. This important and indispensable class must be improved. Their arrogant ideas of exemption from work, of optional inspections, of independent action and irresponsible power, must be eradicated. The only mode of accomplishing this, (and it must be done first or last,) is by learning thoroughly ourselves, and imparting our knowledge practically to them; by directing, in detail, all our planting operations; by frequent and minute inspections of work, implements, stock and laborers; and by enforcing prompt obedience to every order, and rigid accountability in the discharge of every duty, and in the observance of every precept of plantation economy. It is erroneous to suppose that planting is an easy and indolent vocation. Properly pursued, it is one of the most arduous; demanding untiring activity and energy to regulate the negroes, divide and task them judiciously, designate work, mode of doing it, and to observe from day to day that it is correctly done; attend to stock; the manure pit; the experiments going on; with many other matters depending on the variety of his collateral works. And exacting constant mental exertion to acquire a knowledge of all the physical sciences, so indispensable to enlightened and successful planting, and to keep pace with the improvements in the country; and a cultivated judgment, to investigate the thousand theories that are broached, to experiment, to compare facts, to combine and to apply them. And while the overseer may be exempted from very much of the mental labor of the owner, his physical activity should be increased; his time, his efforts, and his thoughts, should be devoted to the welfare of his employer, and he should take the deepest interest in every operation tending to promote it.

But my remarks are extending too far. I intend them as introductory to the request, that you will publish the articles on overseers, signed Franklin: coming, as stated, from a scientific and successful planter, they will carry a weight additional to their intrinsic merits.

A BURKE PLANTER.

* A fact: one instance has certainly come to the knowledge of the writer.

For the Southern Cultivator.

WORN OUT LANDS, SCOOTER AND SHOVEL PLOWS, &c.

Mr. Editor—The worn-out condition of the lands in Georgia, has become a matter of regret to every patriot in the State. To retain the present population, and prevent their emigration; to restore the lands in the State to their original fertility, and even greater productiveness, should be the earnest wish and constant endeavor of her citizens, statesmen and legislators. The Legislature should assist in the great work, by offering premiums for the best improved farms, crops, plows, &c. More than three-fourths of the taxes are raised from the farmers. Can any one object to a few thousand dollars being restored to them in that way? Any assistance in arresting the evil, and restoring the worn-out fields to fertility, will be doing "the State some service."—So, Mr. Editor, if you will print what a plowman writes, you shall have my help.

The destruction of lands at the South, is owing partly to their rolling nature; partly to the heat of the sun; partly to treading by stock; and mostly from imperfect cultivation: which includes want of rotation, want of manure, overcropping, and improper implements of tillage. A few remarks on the last subdivision, as connected with plowing and plows, will, it is hoped, meet the approbation of my fellow plowmen.

Generally, the deeper the ground is broke by the plow, the better for the crop, (except deep sand with a light vegetable mould on top.) If more labor and attention were bestowed on the preparation of land for planting, less labor would be required in cultivation, and the production would be increased. Land, to be well plowed, should be broke at the bottom of the furrow as well as at the top. A plow, to break the ground well, should have a *broad point;* or, if a winged plow, the lower part of the wing should be as nearly horizontal with the point of the plow as practicable to work well, so that it may *cut the dirt loose at the bottom of the furrow.*

Spade culture is considered the most perfect; consequently a plow (in plowing) that approximates nearest to spade work, must be the best plow. The scooter and shovel plows (used almost universally in Georgia) are triangular, forming acute angles at the points, and their work does not imitate, in the least, work done by the spade;* therefore, they are imperfect plows, and cannot do good work in breaking the ground. The *scooter and shovel plows have done more injury to the lands in Georgia, than every thing else;* because the ground is broken so shallow by them, that it is washed off by the rains. They cut a sharp trench into the ground, and leave an unbroken ridge on each side of the furrow. They cannot thoroughly break and pulverize the ground; and in plowing over the second time, they will follow in the furrow made at the first plowing.

Now, Mr. Editor, I have condemned seven-eighths of the whole number of plows in Georgia, comprising scooters and shovels, and I might leave the owners of them where I have found them; but, as I am fond of good plowing and plowers, I will tell them what other plows to use. Besides the improved northern plows, which you can see described in the Cultivator, some of our blacksmiths make plows that are far superior to the scooter and shovel.

Among them, is the scooter dagon, a turning, one horse plow, adapted to light soils; the "*nullifier*," a broad-pointed plow, commonly made to turn the soil half over—can be made to turn it entirely over—adapted to all soils, excellent for breaking stiff stubble land, cutting deep-rooted vines and briars, bedding cotton ground, potatoes, &c., an excellent plow; the coulter, winged coulter, twisted shovel, &c., all of which can be used on the common plow stocks, except the coulter and winged coulter, which require coulter stocks. I know some farmers who have thrown aside the scooter and shovel altogether. They may do for some kind of work, but they are not like patent pills, they won't answer for all complaints.

In traveling through the country, I have often stopped at the smith-shops, and examined the plows. In many shops, the scooter and shovel are the only plows made, except a few sweeps. The farms around such shops are generally badly worn, and the crops poor. In a few shops, wherever I have found an improved variety of plows, the improvement was apparent in the appearance of the fields, and in the growing crops. And where manure was added, the crops were still better.

If the above remarks and facts should save even our small fields from utter desolation, or put one dollar more into the pocket of a brother farmer, it will be very gratifying to a

Plowman.

Butts Co., May 28th, 1844.

"I don't mean that any person ever plowed with a spade, but used it with the hands.

For the Southern Cultivator.

A LEAF FROM THE BOOK OF EXPERIENCE.

HILL SIDE DITCHING, MANURING, ETC.

Mr. Editor—I have been many years a farmer, and for several years past have manured much of my corn in the hill, and some of my cotton. I have acquired some little notoriety among my neighbors, for saving and applying manure; have cleaned out my stables, scraped my horse-lot and barn-yard, and all the manure not needed on my garden has been given to my fields. Surplus cotton seed, too, has not been wasted; yet, in spite of this stercoraceous *profusion*, I have had to look, with rueful face, upon annually decreasing crops and half-filled cribs. I will say nothing of cotton, for I cannot say anything that would be very flattering to my variety, or interesting to the public, either in regard to mode of culture or large production. But I am a man of corn—formerly enjoyed the enviable distinction and title of "corn-seller," and am yet no corn-buyer; but if a turning point is not soon found, I may be reduced to that necessity. I farmed it, in this down-hill fashion, for 15 years—perhaps more; I'll not stop to calculate. Now what have I got by it, and what have I done? Why, I have a house full of children to feed and educate; but, as I did not gather them from the fields, I will drop them from the narrative! Next, I have got an exhausted farm—fields gullied by rain, and a face furrowed by time; the latter being inevitable, I can bear it with becoming resignation; but the former being avoidable, I cannot contemplate it with so much composure.

Now these things have not come upon me like the Texas treaty, without premonition, but gradually, like my children to the table—one every year or two. Seeing the evil of impoverished land, I attempted to avoid it, and for this purpose sought information. Years ago, I read attentively the Albany Cultivator, a good paper in its latitude, but most of its matter about as interesting to a *Southern* farmer as a lecture on the best mode of cultivating Chinese tea would be. Next, I took the Farmer's Register, and then the Southern Planter. These contained too much tobacco, not for my teeth, but for my habits—agricultural habits, I mean. Suffice it to say, I derived but little benefit from either, or all of them. They led me to one thing, however, which, though immediately injurious, may prove remotely beneficial, to wit; whirling my land top-sy-turvy with a turning plow. This may do for rich land and deep soil, but will never do for cow-hide land.

Perhaps, Mr. Editor, in all your geological researches, you have not found out what "cow-hide land" is. If so, I felicitate myself in being able to add to your stock of knowledge. It is land which has soil about as thick over the clay as the hide on an ox. By deep plowing, therefore, a quantity of litter, vegetable matter, was turned under, but too much clay was turned up; the soil was weakened, to be sure; the elements of vegetable nutrition are there, but the roots can hardly find them, or if found, can hardly be extracted by the clay-clamped roots in a dry time. This is the present injury; and the remote benefit is, I have got the soil where the rain can't wash it all away at once, and I will get the good of it after a while.

Manuring and turning over, however, is not all I have done to improve and save my land. Some has been laid off on the horizontal plan; and upon the whole, the level has done some good. Indeed, the plan is very good in moderate rains; but when the bottom drops out of the clouds, and deluges come, there must be some way provided for the water to pass out of the field, or it will make itself one. So you may perceive I have some experience, and have tried various expedients; yet the tendency is still downward.

My next periodical reading on the subject of agriculture, is in the "Southern Cultivator." I say nothing of its merits or demerits; the one might offend editorial modesty, and the other be unjust. It is sufficient for my present purpose to remark, that I found in it instructive essays on hill-side ditching. These I read and thoroughly considered in all their details, and so far approved as to determine to adopt the plan, with some little modification. Accordingly, I *reconnoitered* a field, and armed with the proper implement I invaded it, laid off the ditches, plowed up, and excavated them *secundum artem.* But I made an awful mistake. Your practical and excellent correspondent, Farrer, said—give a fall of two inches to ten feet. Says I, that won't do, the remedy is as bad as the disease; every ditch will become a hideous gully; I'll make an improvement, by giving only two inches to the rod; and I adapted my works to my faith, at least in some of my fields. Luckily, rain came seldom, and light when it did come. The ditches performed their duty finely, because that duty was easy. But a chance came—not of the moon, but of the weather. "The heavens thundered, and the firmament glared with frequent lightnings"—rain descended in torrents, for hours together. Such rains do not fall every year! Many of the ditches were filled with sand, and others demolished; some gullies were formed and others deepened; and much of my land, that I had a title "to have and to hold in fee simple forever," nullified my deed, and started down the river toward Macon. Such was the result on rolling land, where the ditches had not sufficient declivity; but on other fields, where the land was more level, and on rolling lands where the size and declivity of the ditches were sufficient, no damage at all was done. The success was so perfect, that I am now satisfied, that I have found the great agricultural *panacea*, for which we have been hunting these many years. When I have seen not only the soil, but the manure that I have toiled to get on my fields, soon washed away, I have felt dispirited, and sad; and visions—day dreams—of the fruitfulness of Alabama, Mississippi, and *even* Texas, infested my mind. But the ties of nativity, friendship, kindred and comfort, have thus far bound me to the soil of my ancestry; and now the gratifying truth is discovered and established, that the fertility of our farms may be preserved or restored, and that emigration to a wilderness country with its thousand attendant ills is no longer necessary.

I am no enthusiast, Messrs. Editors. My scepticism in regard to the many plausible novelties of the day justifies the assertion. Yet I hesitate not to say, from my limited but satisfactory experience, that ditching, when seconded by other necessary means, can do wonders in the improvement of the face and fertility of our country. No observant farmer will deny or

doubt, that there is, annually, ten times as much soil and litter washed from our fields, as is taken off in the form of produce. Now, if this can be prevented, the period of fruitfulness will be lengthened out for years, even under bad husbandry. Ditching will accomplish this end—and then what manure may be put on "is there," and will there remain, increasing the productiveness, from year to year, in proportion to the kind and quantity annually used, the mode of its application, and the skillfulness of the tillage. I know that ditching "*per se*" cannot enrich land, any more than the President, "*per se*" can annex Texas. But let one be "backed" by manure, and the other by the Senate, and both objects will be accomplished; and I may add, as in a republic, rotation in office is right, so in agriculture, rotation in crops is useful.

Where is the manure to come from, to be applied to our whole farms? From every where. Decayed or decaying vegetable matter is manure, give me this matter, and the fertilizing salts (so much talked of) will be there. If you think not, add more, and no harm will be done. In addition to the places where manure is usually sought, go to the wood-yard, fence corners, pig stye, hog beds, and peradventure the mansion yard, these may all furnish some. The woods and branches furnish it largely. Look at the drifted leaves, intermixed with soil, in swamps and vallies, where they have been accumulating for ages; look at the soil in places inaccessible to the plow; look at the marsh mud—muck you call it; look at all of these, and then say if we have not the elements of prosperity at our command. And don't look only, but gather up, and have it upon your fields: and don't haul by the day or two, or week or two, but make a business of it. Start, as when with axe and mattock, the forest was invaded to clear a field or "open a farm." Next let deep furrows be made at the proper distance for planting. The deeper they are made the better. Fill them with such manure; break the balks deep with that good old-fashioned sub-soil plow, the coulter; then with good cultivation it will be seen that labor thus bestowed on old land, will yield a larger profit, than the same amount devoted to clearing.

If I live, Messrs. Editors, you shall have the result of such an experiment. Far be it from me to say any thing against well-meant or promising plans or exertions to promote the interests of agriculture. Hence I will not condemn the various new-fangleds method of making manure by humid fermentation or otherwise. Thus made, it is doubtless richer and more stimulating, but also more costly in labor and money, than manure produced by spontaneous decay, or by the agency of animals; but I will venture the opinion, that twice as much land may be equally enriched, with a given amount of labor on the plan I suggest, as can be, on the tedeous, manipulating process of Jauffret, adopted substantially by Bommer. If, however, this process is a good one, I wish it success. Of this we shall doubtless soon be informed, as some are testing its virtues by experiment. In the mean time, I shall content myself with the old-fashioned process of humid fermentation, to wit, the teeth of cattle in lieu of crowbars, and their stomachs for vats. But for such materials as they will not lend their inner organs to reduce, I assert my sovereignty, and demand the use of their heels and hoofs, in trampling them to the proper state. COLONUS.

Covington, June 15, 1844.

For the Southern Cultivator.

BEES.

MR. EDITOR—In perusing your invaluable "agricultural periodical," I occasionally see short paragraphs concerning bees. As we derive one of our greatest luxuries from them, perhaps it would not be amiss to tell how the industrious little laborers should be treated.

In the early part of the spring season, as soon as they commence flying out, the hive should be placed in a cool, shady situation. During the whole spring and summer, the hives should be raised from the bench on which they sit, at least once a week, and brushed under to remove the webs which are formed by worms that are highly destructive to bees. As soon as they cease to labor in the fall, the hive should be exposed to the cold, but kept dry. In a cold place, they soon become torpid, and of course they consume but little food; also, they are not "invited out" in the open air, where they would soon perish. In "robbing," or taking the honey from them, it should never be taken out lower than half way down the hive. It is improper to "drive" them from the hive they inhabit into another, unless the hive is defective; for, in doing so, we destroy hundreds of young bees in the embryo state. Yours, &c., UNUS.

Camp Ground, Monroe Co., June 6th, 1844.

NEW METHOD OF OBTAINING CREAM.

We extract the following from the valuable Report of the Hon. Mr. Ellsworth, Commissioner of Patents.

New Method of obtaining Cream from Milk; by G. Carter of Nottingham Lodge, near Eltham, Kent.

The process of divesting the milk of its component portion of cream, to an extent hitherto unattainable, has been effected by Mr. Carter, and is thus detailed by that gentleman in a paper presented to the Society of Arts:

A peculiar process of extracting cream from milk, by which a superior richness is produced in the cream, has long been known and practised in Devonshire; this produce of the dairies of that country being well known to every one by the name of "clotted" or "clouted" cream. As there is no peculiarity in the milk from which this fluid is extracted, it has frequently been a matter of surprise that the process has not been adopted in other parts of the kingdom. A four-sided vessel has been formed of zinc plates, twelve inches long, eight inches wide, and six inches deep, with a false bottom at one half the depth. The only communication with the lower apartment is by the lip, through which it may be filled or emptied. Having first placed at the bottom of the upper apartment a plate of perforated zinc, the area of which is equal to that of the false bottom, a gallon or any given quantity of milk is poured (immediately when drawn from the cow) into it, and must remain there at least for twelve hours. An equal quantity of boiling water must then be poured into the lower apartment through the lip. It is then permitted to stand twelve hours more, (i. e. twenty-four hours altogether;) when the cream will be found perfect, and of such consistency that the whole may be lifted off by the finger and thumb. It is, however, more effectually removed by gently raising the plate of perforated zinc from the bottom, by the ringed handles, without remixing any part of it with the milk below. With this apparatus, I have instituted a series of experiments, and, as a means of twelve successful ones, I obtained the following results:

Four gallons of milk, treated as above, produced in 24 hours, 4½ pints of clotted cream; which, after churning only 15 minutes, gave 40 ounces of butter. The increase in the cream, therefore, is 12½ per cent., and of butter upwards of 11 per cent.

The experimental farmer will instantly perceive the advantages accruing from its adoption, and probably his attention to the subject may produce greater results.

From Mr. Foy on Preserving Butter.

HARTFORD, Jan. 12, 1844.

SIR—In answer to your inquiry, What has been your practice in putting up butter, especially for preservation in hot climates, or for long voyages? I will cheerfully state that I have had considerable experience on this subject, and in some particulars, good success. There are many things required to insure good butter. The butter itself must be well made; that is, worked enough and not too much, and salted with rock salt. This being well done, and the buttermilk all expelled, the butter may be packed in good, white-oak, well seasoned casks, well filled. In cool climates larger casks can be used. In hot climates it is best to have small casks—say from 25 to 30 lbs.—so that too much need not be exposed while using. Then put these small casks into a hogshead, and fill up the same with a strong pickle that will bear an egg, and the butter may be shipped to the West Indies or Europe, and kept perfectly sweet. I have never found saltpetre or sugar of any benefit. Butter of my packing has opened as good in the West Indies as it was in Connecticut. I will remark, that to keep butter in ice-houses, when it remains frozen, will answer, if the butter is to be continued in the same temperament; but if it is exposed to warm weather, after being taken from the ice-house, it wil not keep as long as if it had not been exposed to so cold a temperature.

Yours, respectfully, G. Fox.

Hon. H. L. Ellsworth,
Commissioner of Patents.

From the Maine Farmer.

COMPOST MANURE.

A correspondent, who has just commenced farming, desires to know the "cheapest method of making compost at the shortest notice." This is a desideratum to the farmer; a question in which every one is interested, and which is intimately connected with the fertility of his soil, the abundance of his harvests, and the profit on his expenditure in money or labor, or both. An answer to the question, however, cannot be given, which will *hit* every case, because of the different location, and of the abundance or scarcity of the means, which will exist in different situations. We would advise our friends to seek out a place, if such an one can be found in his premises or neighborhood, where swamp muck can be found in abundance, and of easy access. This word, "*muck*," is a general term, and is usually applied to any deposit of vegetable matter in a moist situation. Sometimes it occurs in a state of dark, finely divided matter, which is, more properly speaking, muck. Sometimes it occurs in the form of fibrous matter, matted and interwoven together, when it is called peat. In each case it contains a large quantity of that peculiar substance which is now called humus, and which contains one of the essential elements of the food of plants. It is, however, in an insoluble state, and while in this state, that is, as long as it cannot be dissolved in the water or moisture which is in the soil, it cannot be taken up by the pores of the roots, and converted to the substance of the plant to which it is applied. The experiments of Dr. Dana, of Lowell, Mass., have proved that the best substance which can be added, in order to change this muck from an insoluble to a soluble state, is alkali. A mixture, therefore, of ashes with it, will bring about the desired change. Leached ashes will answer very well for this, but unleached ashes are better because of their containing more potash, and, of course, require a less quantity of them. The cheapest mode, therefore, of making compost, is, when muck and ashes can be easily obtained, to mix them together in suitable proportions. But our friend wishes to know the quickest mode, as well as the cheapest. Whether this dispatch and cheapness can be combined together, depends very much on circumstances. By hauling muck and ashes into our cattle yard or into the hog-sty, and letting them be there to undergo the changes which will inevitably take place during a six month's exposure to the operations which must act upon it, we get a first rate manure, at a cheap cost. If we mix the muck and the ashes together, and occasionally shovel them over so as to intimately incorporate them, we get a cheaper compost, but not so rich in the nutritive ingredients as if it had been exposed in the cattle or hog yard. The most expeditious mode of decomposing muck, straw, sods, and such like materials, will be to combine them together in a heap, or large mass, and water them occasionally, with what we call a rotten liquor, or in other words, water which is impregnated with vegetable and animal matter,

as is often found in some stagnant "puddle," or pond-hole. Several patents have been taken out in this and other countries, for peculiar modes of mixing these materials, but they cannot be very valuable to the inventors, for the operation can be so varied that the same results can be obtained without following the same course that they do.

The main object in these cases is, to bring on decomposition, and the laws of nature, when all the requirements of decomposition are at hand, will go on and produce this result without the aid of a patent right. These requisitions are—moisture, heat, and oxygen. The materials being packed together, are watered occasionally by the above named liquor, which is poured into holes made by a crow-bar into the mass, and in the course of two or three weeks the fermentation has been so complete as to reduce the whole to a soluble manure.

We will publish, ere long, Jauffret's mode of preparing manure, according to his specification of his mode, which was patented in England, as long ago as 1837. The ingenuity of the farmer will point out to him many expedients for bringing about the desired object of making compost, which the particular circumstances of his situation may require. He must bear in mind that one object is, to reduce vegetable and animal matter to a soluble state, and in a compost, materials are put together in all stages and conditions, from that which is dry and inert, to that which is already undergoing fermentation. A little experience will soon give a person an insight into the "*why and the cause.*"

From the Maidstone (Eng.) Gazette

WASTEFUL MANAGEMENT OF MANURE.

Some idea of this may be gained by analogy. Let us imagine that a farmer keeps three teams of horses, who consume, say two quarters of oats per week. Let the farmer give one quarter each week to the horses, and dispose of the other quarter as follows :—There may possibly be some ruts in the road leading to and from his farm-yard ; let him pour as many as possible of the oats into every one of the horse-holes and ruts of this road, beginning at the gate of the yard, and proceeding to the nearest turnpike-road. There may seem much trouble in all this, but nothing valuable can ever be gained or done without trouble, and this experiment will probably always be conclusive. Some farm-yards are nicely drained, and very frequently the drains run into the horse-pond. Let the farmer insist on one of his laborers (who may possibly have some prejudice against it) pouring a good drill of oats into every drain that leads out of the yard till it arrives at the pond, where he may throw in a bushel or so, and if the drain terminates, as drains sometimes do, on a hard road, let him leave a small heap of oats in every black puddle. When he shall have done this, let him cause some of the oats to be scattered in every direction round his stable, and take every possible precaution so that the birds of the air, the mice and rats of the field, the fishes of the ponds, and the creeping things of the earth, may come in for a share of the oats. The farmer's neighbors may call him mad, but let him not mind this. Ulysses was formerly called mad for sowing salt, but now many people sow salt who are considered sensible, and even clever.

Let the enterprising improver keep perseveringly on with this practice for—say three weeks. On or about this period, the ribs of each of his three teams, when in single harness, will probably form a very respectable representation of a park paling. At this point it is time to pause, and seriously ask himself the question, whether it is wise for a man actually to facilitate the waste and destruction of produce which it has cost him much money to gain, and the economical management of which will produce more money. That which we have imagined it possible for a farmer to do with his horse-food, is not a whit more unwise than the practice of some slovenly farmers with respect to their manures. What oats are to his horses,—manure, and especially the liquid and gaseous portions of manure, are to his fields. Every atom of earth which comes into contact with his dung, preserves for it some of its fertilizing virtues, yet he accumulates it in unpaved yards. Every breath of air that passes over it becomes the vehicle for carrying the volatile gases, in which plants delight, from the farmer's dung-yard to everybody else's field; yet he keeps it for a year uncovered with mould. Every drop of rain which falls from the heavens, dissolves some of its most valuable portions, and conveys it away to loss; yet the good man never dreams of sinking a tank, in order to preserve a substance—every pound of which, Liebig tells us, will suffice to grow a pound of wheat. Nothing can show more clearly than this national waste, the necessity of men being made acquainted with the laws of nature, which can never be transgressed with impunity ; which combine to ruin every man who regards them not : whilst there is not one law amongst them which, if understood, may not be made the ready and willing instrument of his will.

ROTATION OF CROPS.

The following principles are laid down by Chaptal for a rotation of crops :—

I. All plants exhaust the soil. They are partly supported by the earth, the juices from which constitute an important part of their nourishment.

II. All plants do not exhaust the soil equally. Air and water help nourish them; different kinds of plants require the same nourishment in different degrees.

III. Plants of different kinds do not exhaust the soil in the same manner. Plants with spindle or tap roots, draw nourishment from layers of soil in contact with the lower part of the root, while those whose roots are spread near the surface, exhaust only that part of the soil.

IV. All plants do not restore to the soil either the same quantity or the same quality of manure. The grains exhaust a soil the most, and repair the injury the least. While some leguminous plants restore to the soil a great portion of the juices they receive from it.

V. All plants do not foul the soil equally. Plants are said to foul the soil when they promote or permit the growth of weeds. Plants which have not large leaves fitted to cover the ground, foul the soil.

From the above principles, the following conclusions have been drawn :

1. That however well prepared the soil may be, it cannot nourish a long succession of crops without becoming exhausted.

2. Each harvest impoverishes the soil to a certain extent, depending upon the degree of nourishment which it restores to the earth.

3. The cultivation of spindle, or tap roots, ought to succeed that of running and superficial roots.

4. It is necessary to avoid returning too soon to the cultivation of the same, or analagous kinds of vegetables, in the same soil.

5. It is unwise to allow two kinds of plants, which admit of the ready growth of weeds among them, to be raised in succession.

6. Those plants that derive their principal support from the soil, should not be sown excepting when the soil is sufficiently provided with manure.

7. When the soil exhibits symptoms of exhaustion, from successive harvests, the cultivation of those plants which restore most to the soil should be resorted to.

From the American Farmer.

CULTURE OF RUTA BAGA.

If there be any of our readers who desire to raise a crop of Ruta Bagas for their sheep, we would remind them that it is now time to get them in. In the preparation of the soil, we would advise that it receive at least two plowings, and that the first be as deep as a strong team can make the plow penetrate the earth The manure should not be applied until just before the second plowing. It should be plowed in but a few inches, say from 3 to 4. The land should be thoroughly pulverized by repeated harrowings, and then rolled. When this is done, furrows should be traced either with the drill harrow or the corner of the hoe, North and South, an inch deep, and 27 inches asunder. Into these drills the seed should be either sown or drilled, and covered over with a compost made in the proportion of 1 bushel of ashes, 1 of plaster, and 5 of well-rotted manure to the acre ; the seed in, and the compost spread thereon, the drills should be raked over and the patch rolled.

In the preparation of the seed, they should be soaked in a mixture of oil and sulphur for 12 hours, then dried in plaster and sown as taken out of the soak.

When the plants first come up, they should be sprinkled with fish oil, by a mop, and have plaster sown over them early in the morning for several days in succession. When the roots begin to bottle, they should be thinned out so as to stand from 6 to 8 inches apart, and be hoed, without being hilled, sufficiently often to keep down weeds and keep the earth open until they be laid by. This can be accomplished at three hoeings, at intervals of a week or ten days apart.

The soil best adapted to the growth of this root is a sandy loam in good heart, and we will remark, that, to secure a good yield, manure must be liberally dispensed to them ; for, like every thing else of rapid growth, they require to be fed well ; and that, in addition to the animal manure which may be applied, ashes and lime should be added—a few bushels, say five of each, will be sufficient, and will tend not only to increase the quantity but to improve the quality. If practicable, ground bones should form a part of the mixture.

Of the eminent service, in the feeding of sheep, of the Ruta Baga, there is but one opinion. For in-lamb ewes, or those giving milk, they are invaluable; not only serving to maintain the ewes in health and strength, but to increase their capacity for secreting milk and nursing; two things of vast importance for the successful raising of their young.

From the Maine Cultivator.

PULVERIZING THE SOIL.

It was the opinion of the celebrated Tull, that good crops might be produced from the same soil for an indefinite period, simply by maintaining the earth in a finely pulverized state, in order that the roots of the growing crop might the more easily expand in every direction in quest of food ; and notwithstanding the fallacy of the theory, so far as it regards the efficacy of the mere act of pulverization without other physical means, no one can doubt the very great utility of thoroughly refining the soil we intend to crop. A very large portion of the fertility of every soil is derived from the atmosphere, principally through the process denominated æration, and by which it becomes impregnated or imbued with those fructifying gaseous agents, the action of which, under proper circumstances, and the laws of a well balanced and regulated economy, are so indispensable in the primary development and final maturation of the plant. Of the many ærified and volatile substances imbibed by the soil, the most important, perhaps, and valuable, as regards its action upon vegetation, is ammoniacal gas; and which, being copiously evolved wherever large quantities of animal manures are used, or permitted to ferment in a free atmosphere, is greedily absorbed by the soil. Now the capacity of the soil to absorb this gas, depends upon its fineness, its porosity, and the minute pulverization or disintegration of the granules of which it is composed. The more thoroughly this operation is performed, the more copious, of course, will be the influx of this fecundating gas, and the more permeable will the soil be to the roots by which it is to be absorbed and taken up. It should ever be remembered, that, other circumstances being similar the absorbent capacity of the soil is precisely in the ratio of the surface exposed.

DANA'S PRIZE ESSAY ON MANURES.

(Continued from page 89)

SECTION EIGHTH.

Manures Consisting of Salts.

In using the term salts here, to designate a class of manures, I wish to distinguish between these and mineral manures, as they are usually termed. These manures are similar in kind to the salts whose action in cow dung we have already considered. They are truly mineral salts, derived from the mineral kingdom, entering into and forming a part of plants, and from this source introduced into the dung of animals. Their action, whatever be their name, has been explained. But the salts composing the second class of manures now under consideration, are not of mineral origin. They are derived from the animal kingdom. The source from which they are formed is the living process of the animal body. They are animal salts. Here, then, let us divide the second class of manures into animal salts, which are truly manures, both their base and their acid acting as nourishers of plants—and into mineral salts. Here, again, reader, you will find that the few facts which we have pointed out, relating to the food and nourishment of animals, will help us on our way in tracing the source of these animal salts.

It has been already said, that the food of animals is divided into two classes—that which does and that which does not contain nitrogen. All domestic animals eat these classes together. In a few words, let us trace their course after the animal digested them. The one class goes to form fat, or to support the natural heat of the body, and passes off by the skin in sweat, or in moisture of the breath, and all its excess, or undigested part, goes off in dung. The excess of nitrogenous food, all that is not required for repairing the daily waste of the body, or to increase its growth, also passes off in dung, as excrement. This is a small portion, and its effects on the strength of dung have been pointed out. But the wear and tear, as we may call it, of the flesh and blood, the parts which are daily and constantly thrown out of the body as excretions, or old materials, enter the circulation, and pass out of the body in urine. This is the point to which I would call your attention. The undigested food, and the excrements not containing nitrogen, go off in dung. The food and the spent parts of the body containing nitrogen, go off in urine. This last, too, is the course of most alkaline salts taken into the body. They pass off in urine. Here, then, we come to the subject, quite prepared to understand it. The urine is a collection of salts: some are of mineral, others of animal origin. But that which gives the urine its peculiar and characteristic properties, is a substance formed from the nitrogenous food, and termed UREA. Now you need hardly trouble yourself to remember this new name: all I want you to understand about it is, that when urine is exposed to air, it rots; and this peculiar substance is changed to ammonia. That is the point to be remembered. In considering urine, therefore, as a manure, it will not be necessary to point out further the mode of its action, than to refer that of every animal to its salts and power of forming ammonia. The quantity of the last will be in proportion to the quantity of urea. There are other salts of ammonia in urine, and also mineral salts. These affect but little the value of urine as a manure. It is the *urea*, essence of urine, that substance which forms ammonia in rotting urine, which alone makes this liquid more valuable than dung. Hence, reader, if this is impressed on your mind, you will perceive that the chiefest things to be regarded in urine, are: first, the circumstances which affect the quality and quantity; second, the best mode of promoting a change of urine to ammonia; third, the time required for the process; and fourth, the best mode of preserving the ammonia, when formed. You will perceive, reader, that all along I have endeavored to point out the principles on which manures act. If you go by general principles, then for a plain practical farmer like yourself, with only chemistry enough to understand a few of its terms, it must be quite a thankless service to point out to you in detail all the various things contained in urine. All you want to know is this—does urine contain, as solid dung does, water, mould, and salts?

It does. The mould is so small a part, it may be left out of view. The salts are like those in the solid dung—mineral salts—and then we have the peculiar principle, *urea*, which for all practical purposes may be called ammonia. We may, then, with this division, present in a table the composition of the urine of various animals at one glance:

		Water.	Salts.	Ammonia.
Cattle urine, ℔ 100 lbs.		92.62	3.38	4.
Horse,	do	94.00	5.03	.70
Sheep,	do	96.	1.20	2.80
Hog,	do	92.60	1.76	5.64
Human,	do	95.75	1.88	2.36

Now cast your eye carefully over this table; the figures at once tell you the value of these different liquids. The last column gives the true value. The other salts vary much in quantity, and this affects the quality. The actual amount of ammonia in human urine and cattle dung, is about the same; yet in actual practice it is found the effects of urine are nearly double those of dung. Look, now, for the reason of this. In the first place, the principle which gives ammonia in urine, runs at once by putrefaction into that state. It gives nothing else; whereas in dung, the ammonia arises from a slower decay, and the principle which here affords ammonia, may, and without doubt does, form other products. Hence, we have a quick action with the liquid, a slower one with the solid. A second cause of the better effects of the liquid is, that it contains, besides its ammonia, a far greater amount of salts, and these give a more permanent effect.

The amount of salts in human, cow, and horse dung, is about one pound in every hundred. While the urine of the same animals contains nearly six pounds in every hundred. A third cause of the greater fertilizing action, is found in the peculiar character of some of these salts, which are composed of soda, potash, lime, &c., united to an acid formed from urea, in the animal body. This acid is like the acid of saltpetre; it is a nourisher of plants, as much so as is carbonic acid.

SECTION NINTH.

Of the Causes which make Urine Better or Worse, More or Less, and the Modes of Preserving it.

There can be no doubt that the same causes which we have pointed out as affecting the value of dung, affect also the urine.

We have already alluded (in section viii.) to the four chief circumstances to be regarded in urine. And first, of its composition. It will be affected by the age, sex, food, and difference of animal. The process of forming urine is the same in man and animals. Now if we reason here, as we surely may, from analogy, then the effect of age and sex upon the quantity of the essence of urine or urea, will appear from the result of one hundred and twenty analyses of urine, as follows:

	Grs. of Urea.
In 24 hours there are discharged by men,	432
By women,	293
By old men, from 76 to 80 years of age,	123
By children 8 years of age,	208
By children 4 years of age,	70

It will be recollected that each grain of urea is equal to a grain of carbonate of ammonia of the shops; so that a healthy man discharges daily about an ounce of this salt. If, then, other animals are affected by age and sex, as is the human species, then we may say that bulls and oxen give a better urine than cows, steers better than calves, and a venerable old cow gives nearly as much of the essence of urine as two calves.

Food affects the quantity of water, and that acting merely to dilute the urine, renders it weaker in salts for a given amount, though perhaps not the daily amount of salts. Supposing the animal well fed, so as to keep up the wear and tear of his flesh and blood, then as the urine derives it chief value from the worn-out materials of the body, the actual amount of urea daily discharged may be the same, though the amount of the urine may vary considerably. We may increase the amount of salts and acids by particular food, but this can never be continued long enough to change materially the character of urine as a manure. Difference of animal has also a great effect on the quality of urine. The more active, the greater the wear and tear of the flesh, the better the urine in working animals. Where the animal is stall-fed, there, no doubt, the urine is still richer, and the urine of fattening animals is still more valuable. Hence of all animals, commend me to swine, as manufacturers of ammonia. Cast your eye on the table (in section 8) of the amount of urea or ammonia furnished by various animals. No one exceeds the hog. He seems specially formed by nature for this office. He eats every thing. His habits require very little of that class of food which forms flesh and blood. He is a fat-former, a magazine of lard, a real oil-butt, and demands, therefore, the food essential to form fat and keep up his heat. He returns, of course, having little lean meat to form, (nobody would praise him for *that*,) having little flesh to form to increase his size, he returns quickly the waste his body suffers, as urea, which becomes ammonia. But it is only the still, and quiet, and penned animal, which gives this valuable product. If we would cause him simply to produce the greatest amount of his manufactory, without taking into account his labor in shovelling over the compost heap, perhaps no better rule can be given, than the Shaker practice of feeding with lettuce leaves. Having little brains to replenish or build up, and not quick in his nerves, (for be it known to you, reader, the opium of lettuce-leaves is supposed to contribute mainly to the formation of brain and nerves,) the opium-eating hog will return a vast amount of the nitrogen of his lettuce in the shape of ammonia. If now you add to the facts, common to the nourishment of swine, the action of ammonia on mould, as it has been explained, you will see, that he who neglects to fill his yards with mould, and swine to convert it, overlooks one of the cheapest, most effectual, and certain modes of forming manure, which practice and theory unite in pronouncing the surest element of the farmer's success. Not only is the quality of urine affected by age, sex, food, difference of animal, but the season also exerts an influence upon this liquid. The urine of cattle often contains ammonia ready formed in summer, but never in winter. In cold weather, the amount of ammonia, or rather the principle affording it, is less: often it is not one-half in winter what it is in summer. This certainly is a misfortune to the farmer, who generally keeps his cattle up only in winter; but then it is an argument also for the practice of summer soiling.

Secondly, with respect to the circumstances necessary to change urea to ammonia; or, in short words, to fully ripen urine, or to make it a fit manure. These also depend upon the season, in part. It is to be remembered, reader, that this rotting of urine is only fermentation. It takes place because there is a principle in urine which brings on fermentation, just as it does in new cider. Now if it is by fermentation that urine rots, it will take place, as all fermentation does, best at a moderate temperature. The cold of winter will prevent it. Hence your winter manure must be allowed time, as the heat of spring comes on, to ferment, that the urine may be changed to ammonia; and every means must be taken to prevent the heat rising beyond, in the manure heap, or falling below a moderately temperate warmth. These are the circumstances which chiefly promote the change from urea to ammonia.

Thirdly—in regard to the time in which this change will take place, it will require at least one month; and six weeks are better. If urine

be allowed to rot for a month, it fully doubles its quantity of ammonia. In fact, it would have contained more than double the ammonia of fresh urine, had not a portion escaped. This brings us to our fourth point, the best mode of preventing the flying off of the ammonia when this change has taken place.

Much has been said about tanks, and vats, and urine-pits and many plans devised for preventing the escape of volatile ammonia. But when once the action of ammonia upon mould is understood, as we have already pointed it out, I am persuaded, reader, that these tanks, and vats, and urine-carts will appear to you not only expensive and cumbersome, but useless. Your first point is, to save your ammonia, your second is, never to use urine in its caustic or burning state. If you do, you will assuredly burn your crop, as the puddle formed by a cow burns the grass upon which she empties her watering pot. Here the urine forming caustic ammonia acts as would caustic potash, or a lump of stone lime, left to slake upon the grass. You want to change this burning or caustic ammonia into mild ammonia, or to combine it with some substance which has not only that effect, but also keeps it from flying away. Unless you understand, then, the principles of these actions, and apply them too, your labor is all vanity, when you attempt to save your own or cattle's urine.

These principles are, in number, two. First, the principle which changes caustic to mild ammonia, is carbonic acid derived from air, or decomposing mould. Second, the principles which render ammonia less volatile, or wholly fixed, are certain acids formed in mould, as sour mould, or certain salts which give up their acid to the ammonia. Plaster of Paris does this, by changing its lime for ammonia. Now let us go into the reason of this a little, and see if we can understand it. Very slowly and supposing moisture present, the oil of vitriol of the plaster quits its lime and unites to the ammonia, and so changes a volatile into a fixed salt. Now this is a change which has been of late much insisted on, and the practice recommended of strewing the stable and barn-cellars, and even the privies, to save ammonia which escapes in these places. But it is doubtful whether the saving is as great as is usually supposed, for the ammonia arising from the urine is caustic, it flies off as caustic ammonia, that has no effect upon plaster. To produce this mutual effect of ammonia and plaster, the caustic ammonia must previously have been made mild. However, this plan is applicable only on a small scale. Copperas, alum, common salt, potashes, and woodashes, all act to fix the volatile ammonia, and have all been recommended for this purpose. But it is easily seen, that, in employing some of these substances, is to buy ammonia almost at apothecary's price. These practices will be followed, therefore, only by those who place the crop and its value upon ammonia. This is a limited and narrow view. The true and farmer-like, as well as the most scientific and natural mode of preserving the ammonia of urine, is to fill your yards and barn-cellars with plenty of mould; by which I mean truly decayed and decaying vegetable matter, as well as loam. There is no mode more effectual, no mode more economical. Consider now for a moment how mould formed and forming, and ammonia act. Have I not said again and again, that ammonia hastens decay? makes mould more easily dissolved? and cooks the food of plants? That action having occurred during its progress, acids were formed. The ammonia unites with them, loses its burning properties, and becomes fixed. The acids having been satisfied, the ammonia is actually imbibed and retained by mould.

It does not drink it in, like a sponge, but the mould forms a peculiar chemical compound with ammonia. This peculiar compound, while it does not render the mould an easily dissolved matter, yet holds ammonia by so feeble a force, that it easily yields to the power of growing plants. It gives up the stored ammonia at the place where, and the time when, it is most wanted. If you remember these actions of mould and ammonia, it will be as plain as day, that what we have said of the inexpediency and expense of vats and tanks, and urine-carts, must not only be true, but is confirmed by the experience of a host of hard-working, thinking, practical men. In connection with urine, the dung of birds, for instance, domestic fowls of all kinds, and pigeons, may be here mentioned. These animals discharge their solids and what we may term their liquids together. Their urea comes out combined with or forming part of their dung. Now reflecting a moment on the nature of their food, strongly nitrogenous, being seeds, grains, &c., or animals, bugs, grasshoppers, &c., we can understand why their droppings are peculiarly rich in ammonia and salts. The strongest of all manures is found in the droppings of the poultry-yard.

But since these form but a small portion of the farmer's stock, and are never regarded as a principal source of manure, their further consideration may be omitted. It may perhaps be here added, that as from their nature bird-droppings run quickly into fermentation, with warmth and moisture, so they act quickly and are quickly done. They are more allied to sheep dung than to other manures. Their mould not being great, droppings of poultry require to be mixed with decayed vegetable matter, or loam. To this class belongs the manure brought from the Pacific Ocean, under the name of Guano, a Spanish word for excrement. New England farmers can find cheaper sources of salts, to which the main value of guano is owing, and therefore, reader, we shall detain you no longer on this point.

Section Tenth.

Mineral Salts or Manures.

Having thus considered the salts derived from the animal, let us now proceed to those derived from the mineral kingdom. Among these we shall find some whose action is similar to that of the animal salts. That is, they are the true nourishers of plants.

They afford, by the action of the growing plant, the same elements as the animal salts. Of this nature is saltpetre. Now, reader, I want you to understand by saltpetre, not only that well known substance, but also that which has lately been much used in farming, South American saltpetre. This differs from common saltpetre by changing its potash for soda. One step more: I want you to understand by saltpetre, not one salt, but, in farming, a class of salts; that is, a number, having the same acid, which may be combined with several different bases which all act one way. Saltpetre being a salt, of course must be composed of an acid and base. The acid is always aquafortis or nitric acid. The base may be potash, or soda, or lime, or ammonia. These all may be called saltpetre. In forming saltpetre, it is generally that variety which contains lime and aquafortis, which is procured. So far as we understand the action of salts, and this has been fully explained, the action of the varieties of saltpetre is the same; and were it not for the peculiar nature of the aquafortis or acid of saltpetre, the explanation of the action of this salt might be referred to the general laws above set forth. But the acid of saltpetre is composed of volatile ingredients. It is nothing more nor less than a compound of the common air we breathe. Surprising as it may seem, reader, yet it is not the less true, the common air is a mixture of oxygen and nitrogen. What a bland and harmless, yea, what a healthful blessing is air, not only to us but to plants! It is a mere mixture, not a chemical compound, a mere mixture. In every hundred parts, eighty of nitrogen, twenty of oxygen. Yet if you compel, as natural operations are continually compelling the air to unite chemically, so that fourteen parts of nitrogen shall unite to forty parts of oxygen, you will form aquafortis. Now I do not mean to trouble your head further with the chemistry of saltpetre, than merely to say, that having thus shown you the composition and origin of the acid of all kinds of saltpetre, you will readily see, that a substance which affords such an abundance of nitrogen, cannot but be beneficial to plants. This nitrogen may and probably does form some portion of ammonia in the soil. It may enter as nitrogen into the plants dissolved in water as a very weak aquafortis.

We have said so much upon the action of ammonia and nitrogen, that you will perceive how important a part nitre is likely to play in manure. Not only does the nitrogen act here, but the oxygen, the other component of the acid, also acts. It acts upon the mould as air itself would. Besides, the mould of soil and manure imbibes and condenses this oxygen in its pores, and consequently heats a little; so that saltpetre, whether added as such to soil, or formed in manure, as it is always, helps to warm a little the soil, like fermenting manure. So far as these effects are desirable, they may be expected from the use of saltpetre. But this, reader, if you buy your saltpetre, is procuring a small effect at a great price. The action of the alkali of saltpetre is not different from alkali in other shapes; and therefore if you have money to lay out for salts, let me advise you, reader, to spend it rather for ashes than for saltpetre.

(To be Continued.)

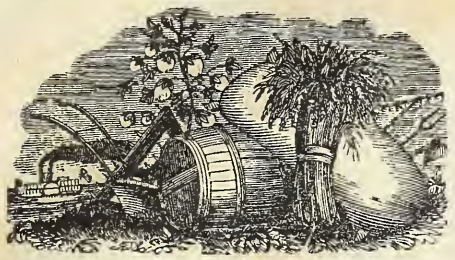
From the American Farmer.

CLAY AS AN AMENDER OF SANDY SOIL.

It is many years now, since we first advanced the opinion that clay, if added to sandy soils, would tend greatly to amend their texture. Since then, we have often repeated that opinion, and we will now add, that a compost made of 10 loads of virgin or unexhausted clay, and the same number of loads of stable manure, if well incorporated together, spread broadcast, plowed in, and thoroughly mixed with the soil turned up, will go farther, last longer, and produce a larger yield throughout a rotation, than would 20 loads of the same quality of manure if applied alone. To us the philosophy of this opinion is obvious, and its reasonableness will strike any one who will take the time to make the necessary inquiries and weigh the operating causes in his mind. Most virgin clays contain very sensible portions of potash, a substance indispensible to the healthful growth of most plants; therefore, in adding clay to sand, we supply a salt absolutely essential to successful culture, and which does not naturally abound, except in very minute traces, indeed, in soils where silex very largely predominates. But this is not the only advantage to be derived from the admixture. Sandy soils, from their porousness—from the absence of the principle of cohesion—lose much of the riches of the manure which may be applied to them, by their natural tendency to yield to the influence of the sun through the process of evaporation.

Another evil of sandy soils arises from the natural disposition inherent in them to infiltration, or in other words, to the sinking of the manure caused by each succeeding rain. Nor is this all; such soils, except when well filled with vegetable and animal manures, possess in a very slight degree the capacity of absorbing and retaining food from the atmosphere. This defect, however, may be cured by the addition of clay. However well porous lands may be manured, unless the season should be a moist one, their products will be comparatively small, because of the escape, by evaporation, of the enriching gases, and from their natural tendency to give up that moisture without which plants cannot prosper.

Plowing-in Green Crops.—Living plants contain in their substance not only all they have drawn from the soil, but also a great part of what they have drawn from the air. Plow in these living plants, and you necessarily add to the soil more than was taken from it—in other words, you make it richer in 'organic' matter. Repeat the process with a second crop, and it becomes richer still; and it would be difficult to define the limit beyond which the process should not further be carried.



WEDNESDAY, JUNE 26, 1844.

Our Bound Volume.—Those of our friends who have ordered the first volume of the Cultivator bound, are informed that they are now ready, and will be delivered to their order. We should have forwarded them by mail, but the postage, which is the same as letter postage, has deterred us. To all such as cannot conveniently send for them, we will send the volume unbound.

The Crops.—Time and space are but allowed us briefly to state, that from all quarters our accounts of the *Cotton Crop* are of the most favorable character. In most districts, the plant appears to be in a much more forward condition than last year—while in others, where later planting has prevailed, a good stand is promised. All that appears to be needed now, is the continued prevalence of the present favorable weather.

Our accounts of the *Grain Crops* are also equally favorable. In some parts of North Carolina, Virginia and Maryland—and some sections of the great grain-growing States of Ohio, Illinois, &c.—the ravages of the fly are spoken of as likely to affect the *wheat* crop materially; but generally, an unusually abundant yield seems to be anticipated. *Oats* are represented as being rather light in most quarters; while the *Corn* appears to be in quite a favorable condition.

Taking into view all sections of the country from which we have advices, our present impression is, that the grain crop, as a whole, will rather exceed, than fall short of, an average one.

The Committee on Agriculture, of the New York Legislature, in their report, remark that "they believe full one-third of all agricultural labor is literally thrown away, by its misapplication."

Corn Oil.—The St. Louis Republican says that a gentleman residing near that city, has recently commenced the manufacture of oil, of fine quality, from corn. It is said to burn with a clear, steady light, in every respect equal to sperm or lard oil, without the smoke which usually attends vegetable oils, and will not congeal in the coldest weather.

Cure for Burns.—The Medical Times says: "After opening the vesicles, if they are formed, the part is dipped in cold water, and then plunged, still wet, into flour, keeping it there for a minute or two; by this means a certain quantity adheres to the part, and prevents the access of the air. It is remarkable that the flour falls in the scales from the surrounding parts the next day, whilst on the burn it remains adherent.

A Memoir on the Origin, Cultivation and Uses of Cotton, from the earliest ages to the present time, with especial reference to the Sea-Island Cotton Plant, including the improvements in its cultivation, and the preparation of the Wool, &c. in Georgia and South Carolina; read before the Agricultural Society of St. John's Colleton, November 13th, 1843, and the State Agricultural Society of South Carolina, December 6th, 1843, and by both Societies ordered to be published. By Whitemarsh B. Seabrook, President of the State Agricultural Society of South Carolina. Charleston: Miller & Browne.

The foregoing is the title of a handsomely printed pamphlet, of 62 pages, for a copy of which we are indebted to Mr. A. E. Miller, Publisher of the "Southern Agriculturist," and which we take great pleasure in recommending to the careful perusal of all our agricultural friends, as a work eminently entitled to their consideration. It is spoken of by all who have examined it, as a production of the highest merit, from the elaborate research which it evinces in the author, and the skill and ability with which he has handled his subject, and applied his knowledge to the elucidation of the science of Agriculture, in the particular branch to which this essay is devoted. We feel assured, therefore, that we cannot do our readers a better service, than in urging them to examine the work in question.

The book is for sale by Messrs. C. E. Grenville & Co. and Mr. T. Richards, in this city. Price 25 cents.

"The Indigator," is the name of a new monthly agricultural paper, published in Hamburg, S. C., by J. W. Yarborough; the first two numbers of which have been received The work is got up in very good taste, and may become a valuable auxiliary in the cause of agriculture. The increased interest which is being excited throughout the South on the subject of agriculture and agricultural papers, is among the most favorable omens of the spirit of improvement abroad in the land.

Fence Posts.—A practical farmer informs the Hartford Times, that in taking up a fence that had been set fourteen years, he noticed that some of the posts remained nearly sound, while others were rotted off at the bottom. On looking for the cause he found that those posts that were set limb part down, or inverted from the way they grew, were sound. Those that were set as they grew were rotted off. This fact is worthy the attention of farmers.

If the foregoing is a fact—of which we should like to have further evidence founded on experiment—it must be in consequence of the absorbent vessels of the tree being reversed, which prevents the dampness of the earth being carried upward with that rapidity which would otherwise be the case.

☞A man in Ohio, well mounted, was urging on a drove of fat hogs towards Detroit, met a charming lot of little girls, as they were returning from school, when one of them, as she passed the "swinish multitude," made a very pretty courtesy.

'Why, my little gal,' said the man, 'do you courtesy to a whole drove of hogs?'

'No, sir,' said she, with a most provoking smile, 'only to the one on horseback.'

Croup.—Two or three spoonsful of strong ley, made of oak ashes, and mixed with molasses, are recommended as a positive cure for croup.

Sprains in Sheep.—The best mode of treating sprains is to immerse the limb in a pail of hot water for half an hour at a time, several times a day. Apply the hot water as soon after the accident as possible.

☞Do not despise the poor. Remember that while honest virtue is often clothed in rags, vice flaunts gaily in satin, and dazzles the eyes with costly jewels.

☞The blood of a white hen, (says the N. E. Farmer,) smeared on a freckled face, and suffered to dry thereon, and afterwards wiped away, clearly takes away all spots from the same.

To take Film from a Horse's Eye.—Blow loaf sugar and a little salt into the inflamed eye, and in most cases it will be relieved. Sassafras buds pounded, and put in water, to stand till it becomes nearly as thick as cream, applied to the eye, is an excellent remedy for inflammation.

☞For sting of the adder, or slow-worm, apply immediately strong spirits of hartshorn.—For sting of bees, apply chalk or whitening mixed with vinegar.

☞Poisons swallowed by oxen are commonly the yew, the water dropwort, and the common and the water hemlock. One and a half pints of linseed oil is the best remedy.

From the Gardener's Chronicle.

ANALYSIS OF SOILS.

The following is a method of analysing soils for ordinary agricultural purposes:—Weigh a convenient quantity of the earth to be analysed, say 1000 grains, dried in the open air; dry the same before a fire on paper, so as not to scorch the paper; re-weigh, and the difference will be the organic matter. Pour a convenient quantity of muriatic acid on the remainder; stir, and when settled, pour it off, and add oxalate of ammonia: the precipitate will be the lime. Mix the remainder with water, and stir it well; when a little settled, pour off the turbid mixture, and the suspended contents are argillaceous, and the deposit siliceous.

SADDLE GALLS.

Saddle Galls are generally occasioned by an unequal pressure on the saddle, or by a saddle being badly fitted to a horse's back, and if neglected they grow into very ugly and troublesome sores. When these inflamed tumors are first discovered, cold water alone is frequently sufficient to disperse and drive them away, if applied as soon as the saddle is pulled off; but when that will not have the desired effect, by washing them twice a day in the mixture I shall here recommend, the cure will be readily performed.—Take of sharp vinegar one gill; spirits of any kind, one gill; sweet oil or fresh butter, one table spoonful: to be well mixed before used.

From the Gardener's Chronicle.

LIME AND SALT.

I tried this mixture on two acres of old grass land, having mixed them in the proportions recommended by Mr. Cuthbert Johnson. A heap was made, and the lime and salt were laid in alternate beds, then mixed up together, and well covered over with soil and sods. After three months, this was applied to the meadow in question; it was in a state resembling mortar, and was with difficulty spread; after it became dry, it was beat to pieces, and spread and bush-harrowed. In many parts of the field, the grass appeared as if it was scorched. It did not grow luxuriantly, and the crop was the worst I ever had—in some parts not worth cutting.

From the Farmer's Monthly Visiter.

HOME AFFECTIONS.

The heart has memories that cannot die. The rough rules of the world cannot obliterate them. They are memories of home, early home. There is magic in the very sound. There is the old tree under which the light-hearted boy swung in many a summer day; there is the house where he knew a parent's love, and found a parent's protection—now there is the room in which he romped with his brother or sister, long since, alas! laid in the churchyard in which he must soon be gathered, overshadowed by yon old church, whither, with a joyous troop like himself, he has often followed his parents to worship with, and to hear the good old man who gave him to God in baptism. Why even the very school-house associated in youthful days with thoughts of ferule and tasks, now comes back to pleasant remembrances of many an attachment there formed, many occasions that called forth some generous exhibition of the traits of human nature. There he learned to tell some of his best emotions. There, perchance, he first met the being who, by her love and tenderness in after life, has made a home for himself happier even than that which childhood knew.—There are certain feelings of humanity, and those too among the best, that can find an appropriate place for their exercise only by one's own fireside. There is a sacredness in the privacy of that spot which it were a species of desecration to violate! He who seeks wantonly to invade it, is neither more nor less than a villain; and hence there is no surer test of the debasement of morals in a community, than the disposition to tolerate in any mode the man who disregards the sanctities of private life. In the turmoil of the world, let there be at least one spot where the poor man may find affection that is disinterested, where he may indulge a confidence that is not likely to be abused.

From the Boston Cultivator.

WARMING LANDS.

Mr. Josiah Lovett, of Beverly, who has been remarkably successful in raising various kinds of vegetables, as has appeared by his superior exhibitions at the Horticultural Rooms, in a late No. of the New England Farmer, gives his mode of warming land, by which he gets vegetables almost as early as they are produced in the vicinity of Boston, though the season in Beverly is at least a week later, and Mr. Lovett's land is moist and low.

His method is, to plow or spade, or in working the land in any way, to do it *while the sun shines clear*, and, if possible, from 11 to 4 o'clock. By this means, the warm surface earth is turned under, the cold earth brought up and warmed, and buried in turn. This is repeated two or three times, on warm sunny days. Seeds planted on land thus warmed, a week or ten days later than on land plowed or spaded but once, will mature their fruit earlier and of a superior size, with the same manuring and attention.

This system is founded on the true principles of philosophy, as will appear evident to every person of reflection, and we doubt not may be turned to a good practical account. The superior crop, from a more thorough pulverization of the soil, and mixing it well with manure, will amply compensate for the extra plowing.

From the Farmer's Monthly Visiter.

ASHES IN THE HILL.

We advise young farmers not to put ashes in the hill with the corn; the ley they make is often destructive to the young roots when they first protrude from the kernel. The ashes may be dropped on the hill as soon as you have planted your field, and this is better than to wait till the corn is up; it is less labor, and it tends better to keep off the worms. Bury neither corn nor potatoes deep; both should lie on an easy bed, for the first shoots tend downward when the soil will permit them. When the earth is moist enough, half an inch of covering, pressed down with the hoe, is better than more.

From the Western Farmer and Gardener.

TO PROTECT VINES FROM BUGS.

A subscriber communicated to us, a few days ago, a fact relative to the destruction of such bugs and winged insects as are injurious to cucumber and melon vines, &c. He has practiced it for several years, and found it very effectual in protecting the plants from the destructive ravages of these insects. The method is as follows: Just at evening, he kindles a small fire, (or if the patch be large, several may be necessary,) that will blaze freely, in some convenient place, where it will not injure the plants. He then, by brushing the plants, alarms the bugs, so as to cause them to take wing, when they fly directly into the fire, and are destroyed.

Scare-Crows.—The best protection for our corn, from the depredations of the crows, is white twine stretched across the field, supported by stakes or poles, in several directions; the appearance of which seem to give these *darkies* an idea of a net or snare, of which they are very shy. For fear, however, they may become accustomed to it, take the additional precaution of tarring, and rolling the seed in plaster.

The Bite of a Rattlesnake.—The most simple and convenient remedy, says a correspondent of the Macon Messenger, I ever heard of, was alum. A piece the size of a hickory nut, dissolved in water and drank, or chewed and swallowed, is sufficient. I have a good authority for saying it has been tried many times on men and dogs, and that they have invariably recovered. I know of some planters whose hands are exposed to be bitten by rattlesnakes, who always have them provided with it, in their pockets, and they have several times found use for it.

Bad Air in Wells.—Never go down into a well which has been at any time out of use; or it it be deep, without trying the air in it. This may be done by lowering a lighted candle—if it burns, there is no danger; but if it goes out, the air is bad, and death would be the consequence of venturing into it. It is said that the air may be speedily corrected by putting into the well, say from half a bushel to a bushel of quick lime, which will absorb the carbonic acid gas—the agent alike deleterious to comfort and respiration.

Farming at Cape Cod.—The farming interests on Cape Cod, appears to be on a rather more precarious footing than any where else, where agriculture is pursued to any extent. A couple of acres of land planted with corn by Mr. Harvey Hawes, at Dennis, was blown away by the wind, a few days since, to such a depth that it was impossible to tell which part remained planted, and which did not. We have heard strange stories of Cape Cod farming before—how they foldered their cows upon codfish, and weaned the calves upon pickled herring, and all that; but this business of having their freehold taken off bodily by a nor'-wester, is a calamity that is quite new to us. Why don't the Cape Codmen *kellock* their corn fields as they do their mackerel boats, or tie up their potatoe patches to a tree, when they see a squall coming?—*Boston Mail.*

To make Water Cold in the Summer.—The following is a simple mode of rendering water almost as cold as ice:—Let the jar, pitcher or vessel used for water be surrounded with one or more folds of coarse cotton kept constantly wet. The evaporation of the water will carry off the heat from the inside and reduce it to a freezing point. In India and other tropical regions where ice cannot be procured, this is common. Let every mechanic or laborer have at his place of employment two pitchers thus provided, with lids and covers; the one to contain water for drinking, the other for evaporation, and he can always have a supply of cold water in warm weather. Any person can test this by dipping a finger in water, and holding it in the air of a warm day; after doing this three or four times, he will find his finger uncomfortably cold.

Face Ache.—The common affection, so often supposed to be excited by a diseased tooth, although the latter fails to be detected—a rheumatic, chronic kind of pain, wholly different from that of tic-douloureux,—is often speedily curable by muriate of ammonia. This salt should be given in doses of half a drachm, dissolved in water, three or four times daily. About four times will be sufficient to test the potency of the remedy. At other times the iodine of potassium, in five or six grain doses, is quickly effective towards a cure. The efficiency of the latter remedy renders it probable that that affectation is of the nature of periosteal inflammation. —*Dr. Watson's Lectures.*

☞Louisiana raised in 1843, 37,173,590 lbs. of Sugar, while Georgia raised 185,758,138 lbs. of Cotton.

☞"Necessity is the mother of invention," as the cook said when she took her night-cap for a pudding-bag.

GARDEN AND FIELD SEED.

A GENERAL assortment of fresh and genuine GARDEN and FIELD SEED, among which are the following:

Red and White Clover,
Blue and Green Grass,
Rye and Orchard do.,
Timothy and Herds do.,
Millet and Lucerne do.,
Seed Corn of every valuable variety,
Seed Wheat,
Buckwheat and Potato Oats,

Kept constantly on hand by the subscriber, all of which are offered for sale at very moderate prices. All orders, by mail or otherwise, executed with neatness and despatch.

VOL. II. AUGUSTA, GA., JULY 10, 1844. No. 14.

DANA'S PRIZE ESSAY ON MANURES.

(Concluded from page 102.)

SECTION ELEVENTH.—*Of Artificial Nitre Beds.*

But there is a fashion in manures as well as in other things, and saltpetre is now so fashionable, that you may be inclined to use it. Be it so. I will show you, reader, how to make it for yourself, and at the same time form a large pile of capital mould. But as you have began to inquire a little into the reason of things, let us go a little into the reasons why the earth under all barns where cattle are kept, why the plaster of old houses and cellar walls, always afford saltpetre. You well know that this is the case, and why? We have already told you that the acid of saltpetre, that is, the aquafortis, is formed of the air we breathe. Now alkalies and porous bodies compel the constituents of air, under certain circumstances, to unite and form aquafortis, and this immediately unites to the alkali and forms saltpetre. The best alkali to compel this union is ammonia. Hence, where plenty of animal matter is fermenting, or rotting, or where plenty of urine is, there, porous bodies being present, saltpetre will be formed. Now this is enough for you to understand the principle upon which I propose to you to form an artificial nitre-bed for your own use. It has been found that the manure of twenty-five cows, asses and mules, in layers of about four inches thick, with layers of the same thickness of chalky soil, first one and then the other, and now and then damped with the urine of the stable, produces from 1000 to 1200 pounds of saltpetre in four years.

The heap is formed under cover, and occasionally shovelled over. At the end of two years, it is a mass of rich mould. It is left two years longer, with an occasional turning over, but it is not wet with urine for the last few months. The dung the farmer has always; he wants the porous chalky body. This may be furnished by spent ashes, mixed up with its bulk of loam. Hence the following rule may be given: One cord of clear cow-dung, one cord of spent ashes, one cord of loam, or swamp muck. Mix the ashes and the swamp muck well, and having hard-rammed the barn cellar floor, or that under a shed, lay a bed upon it four inches thick of these mixed materials; then a layer of dung, three or four inches thick, and so on, till the pile is two or three feet high, topping off with loam. Wet it occasionally with urine, keeping it always about as moist as garden mould. Shovel over once a fortnight for two years. The pile now contains about fifty pounds of several varieties of saltpetre, and mixed throughout with nearly three cords of excellent manure. It may, therefore, be now used according to the farmer's judgment.

By thoughtful management, he may, after the first two years, annually collect as many fifty pounds as he employs cords of cow dung. But, however prepared, nitre affords, by its elements, nourishment to plants. All its parts act. Its alkali acts, and its acid acts.

SECTION TWELFTH.

Ashes.

It is easy to see that salts, whatever be their name or nature, which are likely to be of any service to the farmer, are those only which either enter into and form part of the plants, or which, by the action of their acid or base, act on the earthy parts of soil, or upon the mould. Salts either poison or nourish plants. The first, like the medicines we take, are good in small doses; the second can hardly injure, even by their excess. If we recur to the principle with which we set out early in this essay, that the ashes of plants contain all their salts, then rightly to know what salts are likely to produce good effects as manure, we should first study the composition of ashes. We have in ashes a great variety of substances. They come from the soil. They form a part of plants. The dead plant returns them again to their mother earth, or we, losing the volatile parts of a plant, its mould and ammonia, by burning, collect its salts as ashes. Let us see what these salts are made of. In the first place, you know, all salts are composed of an acid and a base.

The bases are,	*The acids are,*
Potash and soda,	Carbonic, or carbon united to oxygen,
Lime,	Phosphoric or phosphorus
Magnesia,	do. do.
Clay,	Sulphuric, or Sulphur do.
Iron,	Muriatic, essentially com-
Manganese,	posed of chlorine.
Silex, or earth of flints.	

Now if we throw out the carbonic acid, which has been formed in burning, we have left in ashes three acids, which are united with the bases, and may form the following salts in plants, viz: Glauber's salt, Epsom salt, common table-salt, bone-dust, a salt of lime, and what we may term a bone-dust salt of iron, or phosphate of iron, plaster of Paris, or gypsum, copperas, alum, and some other salts, which need not be enumerated. Our list comprises the principal, and those most likely to be used in farming. Well, now, the lesson to be drawn from this composition of ashes is this, that there is scarcely any salt occurring in commerce, which may not be used in agriculture, instead of those found in ashes. In fact, almost all salts which occur in a large way, as refuse materials from manufactures or other sources, have been used, and all with greater or less success, as manures. And if you cast your eye over the acids and bases of common ashes, this seems quite reasonable. It is not expected that a plain farmer, possessing little or no chemical knowledge, should be able to tell beforehand, what the effect of a salt would be, applied to his land; but if he understands what the composition of ashes is, he may be sure that in any quantity in which the salt is likely to occur, it cannot be injurious, provided it is mixed up with plenty of mould, and a little ashes, or alkali, which will kill or neutralize any excess of the poisonous acid.

In ashes, we have one part which may be leached out, and a part which remains after leaching, called spent ashes. Let us see, then, in leaching, what parts we take away. First, we take away all the acids, except the phosphoric. Secondly, we take away nearly all the potash and soda. What is left? The phosphoric acid, and all the bases. It is evident, therefore, that the strength of ashes can never be wholly leached out, if that depends upon the salts. In spent ashes we have nearly all the bone-dust left; and besides this, a portion of what is usually considered the real strength, that is, the potash. This is chemically united to certain of the other constituents of ashes. You cannot leach it out. Upset your leach-tubs, shovel over your spent ashes, mix it up with fermenting manure, where a plenty of fixed air is given off. Here is the secret of the value of spent ashes, so far as the potash or ley strength is concerned. This exposure to air, to carbonic acid, lets loose the potash, which was chemically combined with the other matters. Water would never have done this. Mark, now, a practical lesson taught here by chemistry, and confirmed by experience. *Leached ashes must never be used on wet soil,* if we want its alkali to act. The close wet soil, perhaps even half covered at times with water, excludes the air. The carbonic acid of air, that which alone extracts the alkali from spent ashes, cannot here act. There is this other lesson to be learned from these facts, that it is chiefly the *alkaline* action which is wanted from spent ashes. Hence, no one who thus understands the source, and the true value of ashes, will allow the alkaline portion to be first leached out, unless he can find a more economical use for it than its application as a fertilizer. Perhaps no fact speaks louder, that the great action of spent ashes is that of its potash, than this, that where we prevent that from being extracted, the spent ashes are of little value. If, then, spent ashes derive their great value from the potash, much more will *unleached* ashes derive *their* value from their potash.

Now, reader, the point to which I have led you in these remarks, is this: that the more alkaline any salt is, the better is it for manure. Hence, as a general rule about the use of salts, it may be laid down that the alkaline salts, that is, potash, pearlash, common ashes, barilla ashes, white, or soda ash, are the best. And as these, in all their various shapes, are the cheapest and most common articles, so you need not run after a long list of other salts. Next in value to the real alkalies, are spent ashes, used in a light, porous, open, sandy soil, if you would derive the greatest benefit from them. Next to these comes peat ashes. You well know these are of no value to the soap-maker. But not so to you. They show only traces of alkaline power. But treat them as you did spent ashes. Their power, independent of their bone-dust, which is by no means small, and their plaster, which is still greater, and their lime, which is perhaps the greatest, lies in the *alkali* which is locked up, as it is in spent ashes. Treat them, therefore, as you did spent ashes, and then peat ashes will, and do, afford alkali. So too coal ashes, even your hard anthracite ashes, yield all the substances which spent ashes do. It is easily seen, therefore, when, how and where, spent ashes, peat ashes, coal ashes, are most likely to do good. Perhaps we may not have a better place to state the fact, that a cord of soap-boiler's spent ashes contain about 50 pounds of potash. When we add to this, 117 pounds of bone-dust, and about a ton and a half of chalk, or carbonate of lime, which acts chiefly on the soil, and so comes not now under consideration, it is seen that there is no cheaper source of alkali and salts, to one within reasonable carting distance of a soap-boiler, than spent ashes. They are marl, bone-dust, plaster, and alkali combined.

SECTION THIRTEENTH.

Manures composed chiefly of Mould.

These are of vegetable or animal origin. And first, of animal mould. Here we shall find

that we come, perhaps, better prepared to understand this part of our subject than either of the preceding classes. We have explained the principles which enable us to understand why it is that animal and vegetable substances produce, by decay, identical matters. The only difference consists in the quantity of these matters. Let me here, reader, call to your remembrance the facts we stated respecting the two classes of food, and the two classes of substances formed from that food by animals. A certain portion of that food contains none of that principle which forms ammonia. This portion of food makes fat. Another portion of food contains the substance which forms ammonia. This part of the food forms flesh and blood, and the other parts of the body, skin, hair, feathers, bristles, wool, horns, hoofs, nails and claws, thews and sinews. Now, when a body dies and decays, the mould which it forms will be rich manure, or poor manure, just in proportion as it contains more or less of the substances formed out of that portion of food which furnishes flesh and blood. The fat, therefore, in animal mould, plays a very inferior part to that acted by the flesh and blood. In a word, as I wish to dismiss the fatty matters from our present consideration, I may do this, reader, by stating to you all that you need know, that in decay, fat forms chiefly carbonic acid. If, therefore, you call to mind what we have said about the action of that, you will see how fat acts in manure. But the flesh and blood, and the substances formed from it, give precisely the same things as vegetables do when they decay, that is, water, mould and salts. The great difference between the decay of animal and vegetable matters, is this: that as the animal bodies are far richer in the substance which forms ammonia, so they afford a richer source of manure. The animal body contains that element, in quantity enough, not only to fill the pores of its own mould, but also enough to impregnate a large quantity of mould from other sources. The vegetable body, on the contrary, contains scarcely enough ammonia to fill its own mould. Vegetables differ in the quantities of the elements of food which can furnish flesh and blood, and hence those vegetables are best for manure which furnish most ammonia. We have already remarked on the difference, in this respect, between straws, grasses, and clover. But without going further into this comparison, which can have no other practical bearing than to show you the immense difference in value, in animal and vegetable bodies, in forming manure, we may here resolve the subject into one great principle. The substance which forms flesh and blood, whether derived from plants or animals, alone forms ammonia during their decay, and the mould thence arising, is rich or poor manure, just in proportion as it contains the substance fit to form flesh and blood. Starting from this principle, we find that animal substances, as flesh, fish, fowl, the body generally, including its various forms of covering, hair, wool, feathers, nails, hoofs, horns, claws, &c., afford, in the process of decay, about ten times more ammonia than the straws and grasses usually entering into the compost heap.

The animal bodies give more volatile alkali than their mould can contain. It is given off in such quantity that decay is rapidly hastened. All the signs of putrefaction, therefore, rapidly take place. The quantity of mould being small, nothing holds the volatile parts—they escape and are lost. Now, common sense and practical foresight have stepped in here, from time immemorial, and taught mankind the necessity and the utility of preventing the waste of the volatile and most valuable parts of the decaying animal substances, by covering them in with earth, soil, &c. These imbibe the escaping virtue or strength, and become rich and fertilizing. It remains to state, that every pound of animal carcass can impregnate ten pounds of vegetable mould; or, taking our arable soils as they usually occur, one pound of flesh, fish, blood, wool, horn, &c., can fertilize three hundred pounds of common loam.

You will see, therefore, reader, how little you have now to learn of the necessity of saving every thing in the shape of animal matters, and converting them to manure, by turning them into your compost heap. It is to be remarked, that the dry forms of animal substances undergo the process of decay very slowly, when left to their own action. Wool, hair, flocks, horn-shavings, &c., or even leather chips and curriers' shavings, bear long exposure, and seem quite indestructible. They yet are rich in all the true virtue of manure. They want something to bring this out, to set them a working, to bring on fermentation. Well, on this head we may lay down two rules; the first is, that if buried among a heap of fermenting matter, that communicates a similar change to these dry, animal substances. This is slow work. The second rule is, that if these dry matters are buried in the soil among the roots of growing plants, then these act more powerfully than fermentation, and the dry substances are converted to manure with a speed which may be called quick, compared to the fermenting process.

The practical lesson to be drawn from these differences of action between the fleshy and horny parts of animals, is, that when you want a quick and short action of manure, to use the fleshy and fluid parts: where you want a more slow and permanent action, to commence and long last after the first is over, to use the dryer and harder parts.

If now we turn to the other division of mould, that from vegetables, we find it lacking in the very thing which was superabundant in animal mould. That thing is volatile alkali. The great mass of vegetable mould is always impregnated, but always slightly charged with volatile alkali. There is not enough of the flesh and blood-forming element in vegetables to hasten the decay of vegetable matter, or to convert them after decay into rich manure. Now here, again, not science, but practical common sense steps in, and did step in long ago, and as she taught mankind the necessity of adding soil or mould to the decaying animal matter, so here, to enrich vegetable mould, she teaches that animal matter, or that which is its representative, alkaline salts, must be added to vegetable mould, to make it active. It is not the mould alone which plants want. We have seen all along how nature provides a certain amount of salts in her virgin mould: we, by cropping, exhaust these faster than the mould. We have tons of that, yet our fields are barren. They want, as has been explained, salts.

And now, reader, having been brought by this course of reasoning, to what the mould wants, (i. e. salts,) consider what tons and tons of useless mould you have in your swamp muck and peat bogs, your bassocks, and your turfy meadows. All these, foot upon foot in depth as they lie, are truly vegetable mould, in a greater or less degree of decay. If you dig this up, and expose it to the air, that itself sets it to work, decay is hastened, volatile matters escape, yea, ammonia, the master-spirit among manures, is secretly forming and at work, warming and sweetening the cold and sour muck. Without further preparation, practice confirms what theory teaches, that this process alone furnishes from these beds of vegetable mould, a very good manure. It is already highly charged with all the salts which a plant wants. But experience, doubtless led by the light of the good results of mixing mould with animal matter to preserve its strength, has also reversed the practice, and taught the utility of adding to vegetable mould quickening salts; that is, either the volatile alkali, by composting the mould with stable manure, or alkali in the shape of ashes, or potash, or soda-ash, or lime, or a mixture of these. In fact, whatever substance can, by putrefaction, give off volatile alkali, will, and must, and does, convert vegetable mould, of itself dead and inactive, into a quick and fertilizing manure.

If, then, reader, you pause here a moment upon this fact, and then cast your eye backward over the principles we have endeavored to impress on your memory, you will perceive that there is not, among all the classes and kinds of manure which we have shown you, one which may not be added, or, as is the phrase, composted, with peat, meadow-mud, swamp-muck, pond-mud, or by whatever other name these great storehouses of vegetable matter are called. These are the true sources of abundant manure, to all whose stock of cattle, &c., is too small to give manure enough for the farmer's use.

It is the farmer's business to make a choice, (if he has any but Hobson's,) of what substance or mixture of substances he will use. We have shown him how small a portion of animal matter, one to ten of pure mould, will impregnate that substance. Taking, then, a cord of this swamp muck, we shall find it contains in round numbers, about one thousand pounds of real dry vegetable mould. So that the carcass of an animal, weighing one hundred pounds, evenly and well mixed up with a cord of fresh dug muck, will make a cord of manure, containing all the elements, and their amount too, of a cord of dung.

But it is not from the carcasses of animals that the farmer expects to derive the quickening salts for his muck. This can be the source of that power only to the butchers, (what fat lands they all have!) or to the dwellers near the sea, where fish are plenty. A barrel of alewives, it is said, fertilizes a wagon-load of loam. The carcass of a horse converts and fertilizes five or six cords of swamp muck. A cord of clear stable dung changes two cords of this same muck into a manure as rich and durable as stable manure itself. These are all the results, reader, of actual practice. The explanation of the principle has only come in since the practice, and showed the how and the why of this action.

But the merit of explaining this action, would be, is nothing, if it had not conducted one step further. The explanation of the principle of the action of animal matters, animal manures of all kinds, whether solid or liquid, on muck or peat, has led chemistry to propose, where these cheap and common forms of quickening power are not to be had, to mix ashes, or potash, or soda-ash with swamp muck. Now, reader, this is not an idle, visionary, book-farming scheme. It is perhaps one of the few successful direct applications of chemistry to farming, which speaks out in defence of such book-farming, in tones and terms which bespeak your favorable consideration for the attempt which science is making to lend you, reader, a helping hand. This proposal, the offspring of science, has been carried out successfully by practical men in our own country, and has made its way abroad. Though this is not the place to give you the details of their results, you may rely upon the fact, that alkali and swamp muck do form a manure, cord for cord, in all soils, equal to stable dung.

Well now, after your patience in going over these pages, I hope you will find your reward in this statement. To be sure, it might have been said at once, and so have done with it; but I hoped, reader, and I am sure I have not been disappointed, that you liked to dive a little into the reason of things, and felt that you had farmed too long by the rule of thumb, to be satisfied that it was the road either to improvement or profit. And so among your first attempts at improving your worn-out lands, always supposing you have not a barn-cellar, hogs, and swamp-muck, so aptly called by one of your own self-made practical men, the "farmer's locomotive," I presume you may like to know the proportions in which you may mix swamp-muck and alkali. You can hardly go wrong here by using too much; the greater danger is, you will use too little alkali. But calculating on the proportion of mould in fresh-dug swamp-muck, or peat, it may be stated as a rule, grounded on the quantity of quickening power in a cord of stable manure, that every cord of swamp-muck requires eight bushels of common ashes, or thirty pounds of common potash, or twenty pounds of white or soda-ash, to convert it into manure equal, cord for cord, to that from your stable. Dig up your peat in the fall, let it lay over winter to fall to powder, calculate your quantity when

fresh dug, and allow nothing for shrinking in the spring; when your alkali is to be well mixed in with the mould, and, after shoveling over for a few weeks, use it as you would stable manure.

These quantities of ashes and alkali are the lowest which may be advised. Three or four times this amount may be used with advantage, but both the quantity of alkali and the number of loads per acre, must and will be determined by each for himself. It is a question of ways and means, rather than of practice. But supposing the smallest quantity of ashes or of alkali to be used, which we have advised, then at least five cords of the compost should be used per acre. This may be applied to any soil, light or heavy. But there is another form of this same swamp-muck and alkali, which should be used only on light, loamy, sandy soils, to produce its greatest benefit, though even on heavy soils, if not very wet, it may be used with great advantage. This is a compost of one cord of spent ashes to three cords of swamp-muck. This is decidedly the best mixture which has yet been tried. We have in this all that mixture of various salts and mould which plants want, and both by the action of the mould and by that of the air, the alkali of the spent ashes, which no leaching would extract, is soon let loose, and produces all the effects of so much clear potash or soda.

I have thus, reader, given you a few of the ways by which you may convert your peat-bogs and swamps into manure, when you have neither cattle nor hogs. I have not thought it worth while to go into this subject further, and give you directions for lime and salt, or other matters which might be used. I have given you the most common, and those well known and at hand. All you want, then, to apply these principles of forming composts, is to give them that little attention which will enable you to understand them. And the rest must be left to your practical common sense, without some share of which, farming, like everything else, would be vanity and vexation of spirit.

I would here, reader, take my leave of you, and in the hope that we may again meet to have another talk. There are a great many other points relating to manure, which can be understood only after we have made ourselves somewhat acquainted with the chemistry of soil. Then, having explained that, before the full action of manure can be understood, we must proceed a step further, and consider what changes take place in growing crops, and the effects of these growing crops upon soil and manure. The quantity and kind of salts they extract, and how soil is exhausted. This would lead to the consideration of the quantity and kind of manure to be applied to different soils, and the value of different manures. But there is one other important thing belonging to our subject. Crops exhaust land, but fatten animals. Now this last properly belongs to that part of our subject relating to the changes occurring in vegetables, and their power of exhausting the soil. It will be seen, therefore, that the whole covers the ground called Agricultural Chemistry.

This Essay is only its first part. If it meets your acceptance, I trust it may encourage its author to draw up its second part on soils, and its third part on the effect of crops on soil, and their value as food for animals.

From the New Farmers' Journal.

UTILITY OF GEESE TO THE FARMER.

It has been long remarked that cattle of all kinds are never unhealthy where geese are kept in any quantity; and the reason assigned is simply this, that geese consume with complete impunity, certain noxious weeds and grasses which taint, more or less, according to their abundance, the finest paddocks depastured by horses, bullocks, and sheep. Most farmers are aware of this, and in many places where the beeves appear sickly, geese are let into the pastures, and the soil where they tread is converted for the time being into a sort of infirmary.

From the [Columbia] South-Carolinian of June 6th.

OVERSEERS.

We seldom see communications in agricultural journals in reference to overseers. Yet overseers are most important characters in all planting operations, and it would be as much to the interest of planters to improve them, as to improve their lands, stock, or manner of planting. In fact more, for without improving them it is very difficult to effect any other improvement. Even with the best managers, most of the pleasure, if not profit of planting, depends on the character of the overseer. Planters may be divided into two great classes, viz: those who attend to their business, and those who do not. And this creates corresponding classes of overseers. The planter who does not manage his own business, must, of course, surrender every thing into the hands of his overseer. Such a planter usually rates the merits of the overseer exactly in proportion to the number of bags of cotton he makes, and of course the overseer cares for nothing but to make a large crop. To him it is of no consequence that the old hands are worked down, or the young ones overstrained; that the breeding women miscarry, and the sucklers lose their children; that the mules are broken down, the plantation tools destroyed, the stock neglected, and the lands ruined. So that he has the requisite number of cotton bags, all is overlooked; he is re-employed at an advanced salary, and his reputation increased. Every body knows that by such a course a crop may be increased by the most inferior overseer, in any given year, unless his predecessors have so entirely exhausted the resources of the plantation, that there is no part of the capital left which can be wrought up into current income. And this seldom happens, for such planters usually allow their overseers or other agents to purchase freely what is wanted, so that most losses are repaired—at their cost, to be sure; but they keep no accounts, and never think of expenses. The amount of their reasoning on the subject, is, *that a good crop has been made, and therefore they must be prospering.* And so they go on to their ruin. But they have previously ruined many who might have been fine overseers. Having once had the sole management of a plantation, and imbibed the idea that the only test of good planting is to make a large crop of cotton, an overseer becomes worthless. He will no longer obey orders; he will not stoop to details; he scorns all improvements, and will not adopt any other plan of planting, than simply to work lands, negroes and mules to the top of their bent, which necessarily proves fatal to every employer who will allow it.

It seems scarcely credible, that any man owning a plantation, will so abandon it and his people on it, entirely to a hireling, no matter what his confidence in him is. Yet there are numbers who do it habitually; and I have even known overseers to stipulate that their employers should not give any order, nor interfere in any way with their management of the plantation. There are also some proprietors of considerable property and pretension to being planters, who give their overseer a proportion of the crop for his wages; thus bribing him by the strongest inducements of self-interest, to overstrain and work down every thing committed to his charge. The number, however, of those planters who resign themselves and other property to the tender mercies of their overseers, is rapidly diminishing, partly by their being compelled to sell out, and partly by the impulse which the times have given to agricultural improvement. It is beginning to be distinctly understood, that planting is a profession by which no one can thrive, who does not understand and diligently pursue it; that, in fact, it is a *science*, intimately connected with, and requiring for its full investigation and application, a knowledge of almost all other sciences. And I am happy to add, that no science has advanced more rapidly, within the last ten years, or seems more likely to advance hereafter. Long as agriculture has been practised, it is yet in its infancy, as regards its perfection; and no field opens a wider sphere for genius, or affords a higher promise of fame, than the study and practice of it on scientific principles.

But here, again, we encounter the difficulty of overseers. Few of that large and increasing class of planters who manage their own business, can dispense with agents and sub-agents. It is impossible, on a plantation of any size, for the proprietor to attend to all the details, many of which are irksome and laborious, and he requires more intelligence to assist him, than slaves usually possess. To him, therefore, a good overseer is a blessing. But an overseer who would answer the views of such a planter is most difficult to find. The men engaged in that occupation who combine the most intelligence, industry and character, are allured into the service of those who place all power in their hands, and are ultimately spoiled. He is (or rather was, for there is a manifest change going on) esteemed but a second-rate man among his fellows, who will condescend to take orders from his employer, and manage according to the system of another person. And until this idea is *wholly eradicated*, and the real intelligence of the country, and the true owners of its wealth, can control its agriculture in the minutest details, the advance of improvement must be seriously clogged. What could be done in war, if the orders of the General in Chief were not scrupulously obeyed, from the second in command, through every grade, to the soldier in the ranks? So it is in planting. The planter must understand his business, and he must have agents to carry out his views, from the pitching of his crop to the weaning of a pig. I therefore set it down as the first requisite of a *good overseer*, to OBEY ORDERS: not resistingly, sullenly, and with a protest; but cheerfully, promptly, and with a full comprehension of their spirit, and desire for their success. An overseer who does this much, is worth having, though he may possess more than an average share of the faults of his class. Let him, if he wishes, give his opinion freely, and his reasons for it; but the matter once decided, let him abide firmly, and in good faith, by the old adage, "obey orders, if you break owners."

The next requisite of an overseer, is capacity to understand and execute orders in the proper manner. Without this, of course, his best intentions will not avail you.

The duties of an overseer acting under the orders of his employer, are, first, to attend to the proper management of the negroes; to see that the tasks allotted them, are such as they can perform with reasonable industry; and to take care that they do perform them, and do it properly. The employer should regulate the tasks himself, in the main, and examine the work; but there are a great many details to which he cannot look, and in which the overseer himself will require assistants among the laborers. The overseer should attend punctually to the sick, giving medicine in strict conformity to directions; and, in the absence of the employer and physician, should be capable of using judiciously simple remedies himself. He should cheer and encourage the sick. He should especially take care of the old, the young, and the complaining, for the treatment of whom his employer has, of course, a system suited to his general plantation operations. And lastly, in reference to the management of negroes, it is the duty of the overseer to enforce discipline and subordination, and with as little and as mild punishment as possible. The overseer whose constant and only resort is to the lash, and who expects to remedy by that all the malpractices which he should by his foresight and attention have prevented, is a brute, and deserves the penitentiary.

The second leading duty of an overseer, is to carry the keys of the plantation, and to feel himself wholly responsible for everything upon it. Few negroes, however well disposed, have firmness to resist temptation. It should be placed as little as possible in their way; and they should not be allowed, if it can be avoided, to turn a key. If they are honest, keep them so.

If the overseer cannot see *every* mule fed—as he should do, if possible—he should at least give out all the feed himself, and take measures to be assured that it is applied as directed. This is his especial duty, and one that few employers can ever assist him in; and an overseer who will rigidly perform it, may always save his wages for his employer. Numbers waste many times the amount of them, by sheer neglect in this particular.

The third essential duty of an overseer, is to take care of the stock and tools of the plantation. And here the employer has to rely mainly on him. Whether the work-animals and tools in use are in good condition, the employer can readily perceive; but when they get out of order, he can only give general directions for the most part, which it is the business of the overseer to carry out in detail. So with the cattle and hogs; the overseer is charged with having them fed, and counting them, and accounting for the missing.

If the negroes are well managed, the keys safely handled, and the stock and tools properly taken care of by an overseer, all in accordance with the views and orders of his employer, I pronounce him a good overseer, and should like to employ him, *though his crop should fail utterly* —that is, if he obeyed orders, in managing it. Crops will fail, from bad seasons, bad management, and poor land. For none of these things is an overseer, acting in his proper sphere, at all responsible. God gives the seasons; the employer pitches his crop, plants it, and directs the manner of working it; furnishes the hands, mules and utensils; and has bought poor land, or wilfully allows it to remain so. The overseer is not to blame, *if he has obeyed orders.* The planter who does not himself select the land for planting, and regulate the extent of it properly, according to his force; and who does not adapt his plows and hoes, and systematize his working, according to his soil, is not fit for his business, and should give it up. I had almost said, the planter who does not rest or manure his land, so as to improve it, and carry on a scheme of experiments in planting, should do the same. But it has not come to that yet, though it soon will.

In doing this part, however, let the employer consult his overseer, and treat his opinions respectfully, if he does not adopt them. He will learn much from him; and much also will be learned, sometimes, by consulting his most intelligent negroes. They are often good planters; but he must decide, and do it fully, taking clearly on himself the responsibility, and exacting thorough obedience.

In general, overseers are violently opposed to everything that is new to them in agriculture. The reason is, they are for the most part wholly uninformed in the science of agriculture, and deficient of correct reasoning on the principles of vegetation, the character of soils and manures, and the influence of air, heat and moisture. Their hints are often valuable; their arguments rarely; for where the conclusions of an ignorant planter are just, in three cases out of four his reasoning has been false. And how can it be otherwise, when to understand the simplest process in vegetation, requires a tolerable knowledge of Chemistry, Geology, and Botany? A good overseer will readily engage in every experiment which his employer proposes. If it fails through his neglect, he deserves a discharge at least.

It will be seen that I do not mention being a good planter as one of the requisites of a good overseer. If he could have all the requisites I have enumerated, and did not know cotton from corn, I should not object to him. Save me from an overseer who is what is called "a good planter," with his obstinacy and self-conceit. You have first to unlearn him all he knows, before you can teach him anything. Some knowledge of the art may be valuable, in the employer's absence; but an employer should never be absent longer than he can give orders for the management of the crop, from planting to laying by. As to the idea of planting successfully, and being at any considerable distance from one's plantation; or leaving it for any considerable time, that is an absurdity of which all who have tried it are, I imagine, thoroughly convinced.

In conclusion, let me recommend the only two measures I think practicable, in conducing to the improvement of overseers. Let all those *pseudo* planters who neither understand nor attend to their business, abandon it, and allow the *real* planters the opportunity of selecting from the overseers of the country. It will be to the advantage of all concerned. Then let the *real* planters exact implicit obedience to orders; take their own responsibilities on their own shoulders; and require of their overseers the performance of their proper duties—those duties only, but those thoroughly.

I fear I have exhausted the patience of your readers with this long, rambling article. But I have not exhausted the subject. It is one of deep interest, and demands the attention of all engaged in agriculture. With your leave I may recur to it again. FRANKLIN.

REPORT ON INDIAN CORN.

To the Editor of the Southern Agriculturist:

DEAR SIR—At a meeting of the Agricultural Society of South Carolina, on Tuesday, the 18th inst., the accompanying report was read and accepted, and by resolution directed to be handed to the Editor of the Southern Agriculturist for publication.

Very respectfully yours,
JOS. F. O'HEAR, *Recording Sec'y.*
Charleston, June 19th, 1844.

—

Your Committee on Indian Corn, beg leave to report;—We consider the corn crop as second to no other crop made in the United States; and in this State, the advantage of raising our own supplies would be of great importance, and would save to the State a large sum of money spent annually for corn. Under these circumstances, any improvements in planting, or cultivating this valuable grain, must be interesting. By a judicious use of the plow, and other good management, the crop may be much increased, and in a few years, a full supply for the State might be expected.

In the years 1838 and '39, about 500,000 bushels of corn was imported. From October, 1841, to October, 1842, 360,000; and from October, 1842, to October, 1842, 260,000; showing an increase of the crop of the State, of 100,000 bushels in one year. This increase may be attributed to the efforts made by Mr. Ruffin and others, in recommending marl and other manures, and the proper use of plows.

All plants derive their nourishment from air, water and soil, and the corn plant must have a supply of air and moisture to effect a full development of its growth; and the soil, to do its part, must be well manured and cultivated.

Where the land has been long planted, there is frequently a hard subsoil crust, which must be well broken up by the subsoil plow, to enable the perpendicular roots to penetrate deep into the earth, to obtain moisture for the plant.

In preparing land for a corn crop, we would recommend that in the early part of the winter, a furrow of six or eight inches deep should be made with the common plow; that the subsoil plow should be run in this furrow to the additional depth of ten or twelve inches, and that cornstalks and other manure should be put in this trench, and listed in, when thoroughly wet, with a small plow or hoe, as may be convenient; the land to remain in this state to the period of planting.

We cannot too highly recommend the use of the subsoil plow. By its use the soil will be less wet after great rains, and more moist in great drouth. Mr. Delaplain informs us, that in 1823 he planted a field of 25 acres of corn; that in a part of this field he used the subsoil plow, and in the other part the common tillage. A furrow was made with the common bar share-plow, five or six inches deep, and with the subsoil plow seven inches deeper; that in all other respects, the soil, planting and tillage was the same. In that part of the field where the subsoiler was used, the corn kept its color throughout the season, and produced 50 per centum more than the other. And where the common tillage was used, it suffered much from drouth, and fired considerably.

Mr. C. M. Bement also states that he subsoiled a part of a piece of ground which he planted in Indian corn. The piece of ground was on a light loamy, or sandy knoll. That he subsoiled it in strips, leaving alternate strips not subsoiled, all being manured alike: he ran the subsoiler from eight to ten inches deep. The season proved to be very dry, and where the subsoil plow was not used, the corn was so burnt up that it produced nothing; but where it was used, the corn remained green and flourishing through all the drouth, and produced a good crop.

By the use of the subsoil plow in England, the crop of corn has been increased to an incredible degree, frequently doubled, and in many instances trebled.

The best time for planting corn is about the middle of March. The soil must be moist at the time of planting, or a good stand cannot be expected. The seed corn ought to have been selected with care in the field from those stalks bearing the greatest number of ears. And here we would recommend in the highest terms the use of the coal-tar, to preserve the seed from birds, &c. When the seed is well prepared by the use of coal-tar and soot, and the soil well moistened by a good rain, to be planted at the distance of three feet, the rows being from five to six feet apart; and either one, or two stalks should be left, according to the fertility of the soil. Where the soil is very rich, or highly manured, we think it best to plant at two feet apart, and to leave two stalks.

As soon as the corn is up, the plow ought to be used in breaking up and pulverizing the earth between the rows, and when five or six inches high, the best plowman ought to run a furrow as near as possible to the plant, the bar side of the plow being next to it, and the other plowmen may break up the intermediate space between the rows. At this period the plowing ought to be deep and close, breaking up, and pulverizing well the soil. By porosity of soil, the air is admitted, and a larger quantity of organic and inorganic food for the plant, is afforded.

In dry weather the oftener the plow is used the better, until the corn is about one third grown, after which, the plow ought to be laid aside, and the cultivator or hoe-harrow used in its place. In wet weather the plow ought never to be used. Corn is benefitted at all periods of its growth, by the application of manure on the surface, over the roots. If the drouth is great, and the corn far advanced towards maturity, the surface crust must be broken, and the earth frequently stirred lightly to admit air and moisture to the roots, but care must be had not to disturb or cut the lateral, or surface roots.

About the time corn is maturing, brace roots shoot out from the joints near the surface of the earth. These roots frequently strike deep into the earth, affording both nourishment and support to the plant. If a high hill has been made, these roots shoot out higher upon the stalk where it is brittle, and likely to be snapped off the first high wind. If there be little or no hilling, the corn would bend and yield to the storm, and rise again, having sustained little, or no injury. This would be particularly the case, where the soil is very fertile, and highly cultivated.

Well grown corn has from forty to sixty large roots extending from the joints under the ground, which, with the tap-root, penetrate deep into the soil, if not obstructed by a hard subsoil. From these large roots innumerable small fibrous roots shoot out in all directions towards the surface, extending across the rows five or six feet, in search of nourishment for the plant. The large perpendicular roots afford moisture, and the small fibrous roots, food to the plant. The deeper the perpendicular roots penetrate the soil, the less injury the plant will sustain from

drouth. And the more the surface has been broken up and pulverized, the further the surface roots will extend in search of nourishment, to mature fine and large ears. We would here recommend, that the corn should not be turned down too soon, by which error, the quality of the corn is frequently much injured.

JOHN H. TUCKER, Chairman.

June 18th, 1841.

From the Farmer's Cabinet.

TREATMENT OF SICK ANIMALS.

There are many erroneous notions prevalent in the community, respecting injured or diseased domestic animals, and such unnatural or injurious practices as a consequence of these incorrect views, that no apology is necessary for an attempt to subserve the cause and interest of these useful creatures which, if they had tongues to speak, would tell sad tales of the wrongs to which they have been, and still are, too often subject.

We do not propose to give an essay on the particular cases that require attention—our object is rather very briefly to ask the owners of domestic animals to be guided by a few correct principles, which are applicable to nearly all cases, and which will at least prevent us from doing harm, and be the means, probably, of doing much good.

In the first place, then, we would insist that when an animal is well he never requires any medicine; and when he is sick, we would protest against his being dosed with articles that are said to be 'good' for a particular disease, without any reference to its violence or the symptoms, as common sense would dictate, that remedies the most opposite in their character and effects, may be equally advantageous in different periods of the case.

Always distrust a man and the remedy, when your friend declares that an article is *always good*, or *a certain cure* for a disease, without reference to its symptoms—prescribing for the name of the disease itself—this is the very essence of quackery, in man or beast.

A large portion of the diseases of animals closely resemble those of the human family, and require a treatment conducted upon the same general principles—with some variations and some peculiarities, it is true; but none of those outrageous departures from common sense, which are too frequently witnessed.

A horse with pleurisy, or inflammation in the lungs, or apoplexy, requires a widely different treatment from one with cholic or worms There is no more mystery about the disease of a horse or an ox than about those of a man, and a violation of natural laws is as productive of pain and injury in one as in the other.

There is too great a propensity, everywhere, to resort to active treatment in all cases—a feeling that is encouraged by the ignorant or designing for selfish purposes. An adviser in sickness is often most useful, and shows most skill, where he only tells us what is to be avoided and waits for indications for more active measures—doing little more than preventing ignorant but well-meaning persons from interfering with the salutary and useful changes that may be going on.

Remember that there is a restorative power in nature, to which it is always better to trust, than to direct active remedies without knowing for what particular purpose they are given.

There is never occasion for the administration of the disgusting combinations which the poor animal is made to swallow, from the mere whim of an ignorant horse or cow-doctor. Many a fine beast has been lost by his owner trusting to such prescriptions.

When your animal has fever, nature would dictate that all stimulating articles of diet or medicine should be avoided. Bleeding may be necessary to reduce the force of the circulation—purging, to remove irritating substances from the bowels—moist, light, and easily digested food, that his weakened digestion may not be oppressed—cool drinks, to allay his thirst, and to some extent, compensate for diminished secretions—rest and quiet, to prevent undue excitement in his system, and so on through the whole catalogue of diseases—but nothing to be done without a reason. Carry out this principle, and you will probably do much good—hardly great harm; go on any other, and your measures are more likely to be productive of injury than benefit. But as we have before said, our object now is not to speak of diseases in detail; it is rather to encourage our agricultural friends to *think* before they *act*; to have a reason that will bear examination for every step in the management of a sick or injured animal: to remember they have a powerful assistant in *nature*, (being fairly used,) and that specifics, as they are called, are much fewer and less to be trusted, than their proprietors would have us believe.

We might, indeed, almost sum up what we would desire, in one general direction of five words:—TREAT YOUR BRUTES LIKE MEN.

From the Western Cultivator.

COUNTRY LIFE.

"God made the country, and man made the town."—*Cowper.*

At this season of the year, when Nature has resumed her beautiful attire, and decked her awful aspect with the radiant smiles of gracefulness and love, how much ought he to felicitate himself, who has early cultivated her acquaintance, and is now her well-tried and chosen companion. His solitary walks, amid her old familiar scenes, are fraught with light to his soul. With the prospect of woods, and meadows, and flowers, and "every green thing," with the voices of winds and waters, old pleasant memories throng into his heart, and noble aspirations start to life, adding a glory to his future hopes.

What farmer's boy has not dwelt with rapturous delight on the hallowed associations of his childhood; or his labors in the field, and his rambles in the woods, or his every day sports, and his holyday glory; his mimic mill-dams, and stupendous domes, scarcely inferior to the Emperor of Li'lipot's palace; his excursions after wild plums and black haws, not to mention walnuts and hickory nuts; the incomparable exploits of the sugar-making season; his school-boy days, and all those things which he knows so well, yet cannot find words to describe, even to himself. It is really a melancholy thought, that the happiest period of our lives, (as we afterwards clearly discern,) flies away ere we are sensible of its priceless enjoyments.

I do not make pretensions to any uncommon enthusiasm in regard to these matters, nor am I at all indisposed towards looking with sanguine hopes into the future; yet I certainly would not resign the pleasing memory of the past, for all my future hopes of this world. As the days of my boyhood are verging to their close, I hope I shall find indulgence in regretting the everlasting departure of that delightful season. I intend, as the last act of my boyish life, to write a tribute to those golden hours of thoughtless content and unmingled happiness.

It is in this spirit that I delight in the associations which the season calls forth. Even the wilderness of uncultivated and unadorned nature awakens pleasing emotions. The tall poke-weed by the highway side, the white blossomed elder, the wild rose, and plum, and apple tree, the willow overhanging the stream,—all these have an inexpressible charm. They lead back our thoughts to the time when "the unpruned forest" waved over this fair country, and caused us to reverence the memory of those iron men who made the wilderness blossom as the rose, as the heritage of their posterity.

While thinking of this subject, I will make a suggestion which has often occurred to me concerning the planting of trees. Every spot of ground unfit for cultivation, should be planted with a useful or ornamental tree or shrub. There is no occupation more pleasing, healthful and innocent. And setting aside all other advantages, it would greatly add to the beauty and moral appearance of the country.

But to return. It has often struck me, at first thought, in viewing a populous town, as something bordering on the ridiculous, that men should huddle together amidst noise and filth and confusion, carefully economising the paltry space, while Nature's boundless domain, rich in all her most precious gifts, opens a *free range* around:

"Pure flows the limped stream in crystal tides,
Thro' rocks, thro' dens, and ever verdant vales,
Till to the town's unhallowed wall it glides,
Where all its purity and lustre fails."

I have no spite against towns or their inhabitants, yet I can appreciate the feelings with which a backwoodsman would survey these little things of man's contrivance—the theatre of his vanity; the feelings which caused Daniel Boone to loathe the effeminate train which followed in his footsteps, and sickened his great soul with the bitterness of human pride. I can truly say, with regard to divers little villages within my knowledge, that if the ground they occupy was devoted to cultivation, it would greatly improve the aspect of the country and the morals of the inhabitants. There is something in a city life which contracts the mind, and unfits it for the contemplation of the beautiful and grand in creation. The greatest men of our country and of the world were NOT born and bred in cities. Very seldom have they furnished the world with a George Washington, or a Robert Bruce; such *plants* requires a better *soil*. Like the oak "monarch of the hills," they rise proudly from the soil, until their boughs spread broad and high in the face of Heaven, and the tempest assails them in vain.

Let us rejoice, my honest, sturdy, independent brethren of the plow, that our lot has been cast in circumstances so highly favorable to health, virtue, and prosperity; and we will bless the memory of our fathers for bequeathing to us this legacy of freedom and happiness. There is no human dignity superior to yours, and no other country on earth in which talents and virtuous independence find so congenial an atmosphere. If you have learned to view things in this their true light, you will never give way to a repining spirit, nor look with longing eyes on the charms of wealth and state; and, least of all, upon those callings brought forth and nourished by ignorance, for the support of idleness and knavery. The proudest votaries of ambition have in every age paid a silent but expressive tribute to the surpassing dignity of rural life, in finally courting retirement, the spontaneous and innocent pleasures which it affords. Wisely did they act, when wearied with the unsubstantial vagaries of the world, and the vanity of popular applause, in repairing to that living fountain of bliss vouchsafed by Providence to the restless children of men; but wiser had been their course, had their footsteps never strayed from the flowery banks of its refreshing waters:

"For the calm comforts of an easy mind,
In yonder lonely cot delight to dwell,
And leave the statesman for the lab'ring hind,
The regal palace for the lowly cell."

Wayne County, Indiana. ISAAC JULIAN.

ECONOMY.

M. SAY, the celebrated French writer on political economy, has the following story:

"Being in the country, I had an example of one of those small losses which a family is exposed to through negligence. From the want of a latch of small value, the wicket of a barn-yard, (looking to the fields,) was left open; every one who went through drew the door to, but having no means to fasten it, it re-opened. One day a fine pig got out and ran into the wood, and immediately all the world was after it; the gardener, the cook, dairy maid, all ran to recover the swine. The gardener got sight of him first, and jumping over a ditch to stop him, he sprained his ancle, and was confined a fortnight to the house. The cook, on her return, found all the linen she had left to dry by the fire burned; and the dairy maid having ran off before she tied the cows, one of them broke the leg of a colt in the stable. The gardener's lost time was worth

twenty crowns, valuing his pain at nothing; the linen burned, and the colt spoiled, were worth as much more. Here is a loss of forty crowns and much pain, and trouble, vexation and inconvenience, for the want of a latch which would only cost three pence; and this loss, through careless neglect, falls on a family little able to support it.

BARBOUR COUNTY AGRICULTURAL SOCIETY.

A regular meeting of the Barbour county Agricultural Society, attended by a numerous audience, both of ladies and gentlemen, was held at Glennville on the 29th ult.—the President, Col. John L. Hunter, in the Chair—the Secretary being absent, D. M. Seals was requested to act as Secretary *pro tem.*

The President, in accordance with the provisions of the laws of the Society, delivered a regular address; in which, among other topics of interest to the farmers, he brought to the notice of the Society, the new and improved system of producing manure: for the process, fertilizing qualities, &c., of the same, he referred to and read extracts from the Southern Cultivator. He also directed the attention of the farmers to the improved mode of raising the sweet potato and Indian Pea plant.

At the close of his remarks, Col. McDonald, Ex-President of the Society, was called for, and responded in his usual felicitons and eloquent style,—making a stirring appeal to his brethren of the Agricultural fraternity, in behalf of a scientific system of agriculture, as the only means of rescuing the new lands from waste, and of restoring their old lands to their former vigor and productiveness. He alluded to the ladies, in complimentary notice of the benefits which would accrue to the cause from their zealous co-operation. He concluded his remarks by a happy reference to Horticulture, as being in close connection with Agriculture, and warmly recommended to the fair ladies of Glennville, the formation of a Horticultural Society.

Mr. Bobo, from South Carolina, being present, was requested to address the Society, to which he replied in some *very interesting and practical remarks.*

In compliance with the wishes of the Society, the Rev. Sereno Taylor delivered a short and interesting lecture upon the subject of Meteorology, and read from a diary of the past season, kept by himself.

Col. Alexander McDonald offered the following resolution, which was adopted:

Whereas, a State Agricultural Society has been regularly organized, and a statue passed by the Legislature of Alabama; and whereas, we believe much good to the farming interest of our State would result from a lively regard being had by the farmers generally, in the State Agricultural, as well as in the county societies. Be it, therefore,

Resolved, That we, as members of the Barbour County Agricultural Society, feeling a strong desire for the prosperity of the State Society, will do all in our power to keep alive so important and valuable an institution, by preparing and forwarding from time to time, reports of the state of the crops, within the bounds of our society; and will exert all other possible means for the advancement of the cause of the State society, and that we now call on our brother farmers throughout the State, to join in so laudable an object. And we suggest to the officers of the State Society to make arrangements for holding an Agricultural Fair, at least once a year; and that we respectfully request the Southern Shield, and all other papers in the State friendly to Agriculture, to publish the above resolution.

Col. McDonald then offered the following, which was also adopted:

Whereas, much good would accrue to the cause of Agriculture in the county of Barbour, by frequent meetings of the farmers, so as to enable them to discuss many important subjects relating to Agriculture, and as there is not time for such purposes at the quarterly meeting of the Society, be it, therefore,

Resolved, That a Farmers' Club be established at Glennville and one at Eufaula, which shall hold monthly sessions for the purpose of discussing such subjects as refer alone to Agriculture, Horticulture and Mechanic arts.

A resolution was then passed, requiring the President to appoint committees from the various sections of the county embraced by the society, whose duty it shall be to examine and report to the society the state of the crops in their respective portions of the county. The names composing the above committee to be published hereafter.

The meeting then adjourned.

JOHN L. HUNTER, Pres't.

D. M. SEALS, *Sec. pro tem.*

From the Western Cultivator.

THE YOUNG FARMER'S CATECHISM.

It is my wish, in the following series of questions and answers, to be intelligible. I shall, therefore, endeavor to write with as much plainness as the subject will admit; and if there are any who may consider these essays to please and instruct, worthy their attention, who require further elucidation of any parts of the catechism, I will, upon notice given in the Cultivator, endeavor to supply their wants. Writing, as I do, under many embarrassments, and in haste, I may not always treat the subjects as pertinently as they deserve, nor as lucidly; it is for this reason I make the foregoing offer,—of which I hope the young, interested farmer, will avail himself, if he should find it necessary. Don't be alarmed at a few terms which may be new to you, and call them hard words; the simplest words were once hard to the infant; the hardest words may become plain to you. Endeavor to understand them. There is no business which is not prosecuted with more alacrity, when the principles by which it is conducted are understood.

COMPOSITION OF PLANTS.

1. What are plants composed of? All plants consist of one or more of the following elements: carbon, oxygen, hydrogen, nitrogen, chlorine, iron, iodine, lime, magnesia, manganese potash, phosphorus, silex, soda and sulphur.

2. I know that carbon or charcoal exists in plants; for it is the result of the partial combustion of wood, which leaves the coals or carbon on our hearths: I know that the four next named constituents are gases or air; and I know that potash exists in plants, for we obtain it from the ashes. But what evidence is there that the other substances enter into the composition of vegetables? Chemists have analyzed the ashes of numerous plants; and have proved conclusively that the elements referred to, exist in them. Iodine is procured from sea-weed, and is a valuable medicine. Soda is likewise manufactured from the ashes of marine plants. Silex or pure flint may be seen on the outside of scouring rushes, cornstalks, ratan, and other hard-surfaced plants. It is so abundant in some, that fire has been elicited by striking two pieces together. While traveling on the Grand Prairie some years ago, I obtained a considerable mass of sulphur, resulting from the combustion of a haystack set on fire by lightning.

3. Admitting that all these substances exist in plants; how can we account for the presence of gum, and India rubber, the various fixed and volatile oils, rosin, starch, sugar, wax and numerous acids?—These are all compounds, consisting wholly of carbon, oxygen, hydrogen and nitrogen; principally of the first three, very numerous as the substances are, which are found in vegetables; they are all formed, wood, gum, sugar, acids, and every thing else, out of the few elementary principles named in the first answer.

4. What! all this variety of substance, the bitter and the sweet, the sour, the tasteless, the acrid, the nutritious, the poisonous,—all these properties, the result of the combination of the same elements! How is it possible for these contradictory virtues to arise out of the union of the same principle? The difference in these substances depends solely upon the principles being united in different *proportions.* A very interesting instance of the wonderful effects of changing the proportions of the constituents of a chemical body exists in the combination of oxygen and nitrogen: these gases mixed together in a certain proportion form the atmosphere, or air which sustains the whole living creation; combine with the nitrogen a larger proportion of oxygen, and we produce the exhilerating gas, with the ludicrous effects of which, when breathed, many are familiar. increase the proportion of oxygen, and the result will be an irrespirable gas; and still another proportion of oxygen, and a weak acid will be produced: add more, and a stronger acid will be made: add still more, and we shall have the powerful acid called aquafortis! What a contrast is seen in the two extremes! At one end of the series of combinations* stands the life sustaining atmosphere: at the other, the deadly aquafortis! So in the vegetable kingdom, we shall find a variation in the proportion of a few of the elementary principles named in the first answer, produce the most marvellous difference in the products.

5. If these few elementary substances constitute all plants and all the products of plants, it is evident that the plants must be supplied with them in some manner. Whence are these substances then obtained? From the earth and from the atmosphere.

6. But do these principles exist in all parts of the earth and atmosphere?—The atmosphere being a fluid mass, is constantly in motion: and the wind which is now passing by us, is carrying the fertilizing matters with which it may be charged, into other regions; and thus the exhalations from the earth are mixed with great uniformity, with the air. But it is not so with the earth: there are many parts of it which are wholly deficient in some of these principles; and as there is no natural, universal blending of earth from all parts of the globe, producing a uniform mixture of the soil, the deficiency must be supplied by artificial means: and this constitutes an important part of the art of husbandry.

7. Then there must be land in which some plants will not grow, for want of some essential constituent. How can the quality of the soil be determined? By analysis or by cultivation. If any given plant as wheat, hemp or grass, flourishes on the soil, we know that all the necessary constituents of the plant exist in the soil. But if any of these principles are absent, the plant can no more thrive, than an animal can live without provender. It is then necessary to ascertain what constituents are lacking, and to furnish the soil with them. As different parts of plants are sometimes differently constituted, one part may grow luxuriantly and other parts be dwarfish or defective for want of its proper food. It is important, therefore, to consider what part of a plant fails, and then knowing the composition of that part, we may conjecture the defects of the soil and proceed to improve it with a prospect of success. It is possible, and not uncommon, for the stalk and leaves of wheat to grow exuberantly, while the grain is stinted in its development: or the grains may be perfect, and the leaves and stalk comparatively small.

Richmond, Ia. J. T. P.

STRAWBERRIES.—Great efforts are making in the western country to perfect the culture of the strawberry. Mr. Culberston, of Kentucky, residing on the banks of the Licking river, keeps 60 hands constantly employed in picking strawberries, and sends 125 bushels *daily* to the Cincinnati market. So says the Boston Transcript. (A large story, that.)

AN INDEPENDENT WOMAN.—Talk, indeed, of your pantomine and gaudy shows; your processions, and installations, and coronations! give me a beautiful sight, a neat and smart woman, heating her own oven, and setting her own bread! And if the bustle does make the sign of labor glisten on her brow, what man would not kiss that off, rather than lick the plaster from the cheek of a dutchess?—*Cobbett.*

*The atmosphere is, however, a mechanical mixture of the gases, not strictly a chemical combination.

WEDNESDAY, JULY 10, 1844.

POULTRY.

It is scarcely credible how valuable is the poultry in the United States. By the census of 1840, it was returned at $12,176,170. N. York contributes $2,373,529, which is more than the value of all its swine, hali the value of its sheep, the entire value of its neat cattle, and five times more than the value of all the horses and mules in the State. These facts are derived from a publication of Harper's, called the American Poultry Book.

CHEAP GIN-BAND.

A planter residing in the parish of Tensas, (says a Louisiana paper,) informs us that during the present ginning season, he has dispensed with the use of leather for gin-bands, substituting in its stead a band made of stout Lowell cotton. The strips are cut to the proper length and doubled four times, and require splicing but at one place, and are sewed with strong thread. It is superior to leather from the fact that it runs more slack and is materially lighter, and can be used at least two seasons: the saving in cost is alone sufficient to induce any one to try the experiment. We are assured of its success by the gentleman to whom we are indebted for the information.

A NEW SUBSOIL PLOW.

We saw, a few days since, says the Boston Cultivator, a subsoil plow of novel construction, designed and made by Capt. Chandler. It is well constructed for strength, for running steady and keeping its true position with very little labor of the plowman, and for a thorough and deep pulverization of the soil, with a moderate draught. It will run fifteen inches deep below the wake of another plow. He has subsoiled several acres with this plow, running from 12 to 15 inches deep after a common plow that went 6 inches deep. The soil was clayey, full of small stones, and now and then one of a good size. A team of three horses was amply sufficient, and some over an acre was plowed in a day, leaving the soil so light that it was difficult to walk on it.

☞The Cincinnati Atlas states that their market is bountifully supplied with strawberries, at 5 cents a quart, some of which measure from 4 to 5 inches in circumference.--Oh, our mouth!

☞A writer in the Tennessee Agriculturist, states that chickens or fowls fed with corn ground coarse, as for hominy, will never have the gapes.

☞Panes of glass may easily be removed by the application of soft soap for a few hours, however hard the putty has become.

For the Southern Cultivator.

CAMAK, GA., June 27th, 1844.

MR. EDITOR—As I do not recollect to have ever seen any remedy in your valuable paper for the blind staggers, I have thought proper to send a remedy which was never known to fail when applied in time.

For Blind Staggers.—First, bleed freely; then take 4 oz. of aloes, 1 oz. gum-myrrh, dissolve them in spirits and water, or spirits weakened with water: a quart of spirits is sufficient, and the same amount of water. When well dissolved, take about one-fourth the amount, and drench the animal, and continue to give it every fifteen or twenty minutes, until the animal is relieved.

Respectfully, &c.,

WM. H. EDWARDS.

TREATING CUCUMBER BUGS TO EGGS.

A writer in the Newburg (N. Y.) Telegraph says that he has found a way to save his cucumbers from the bug, (whether striped bug or any other, he does not say,) by giving them a good dinner of shad's eggs. They like fish eggs so much better than vegetables, that they leave the latter for the sake of eating the former. He had put some of the above material around some grape vines to increase their growth, and he thought he would apply some to his cucumbers, when lo! and behold! the bugs which had resisted all attempts to drive or choke them off, immediately left the vines and attached themselves to the fish offal.

Now, if fish eggs will lure them from mischief, we presume the fish itself would; and if fish, perhaps other animal matter would. We see but one objection to this course; that is this: it is not much of an object to raise bugs by feeding them high, and letting them go *scot* free, to come out in swarms another year to eat up your gardens, if there are no fish eggs spread for them.

NUTRITIVE PROPERTIES OF FLOUR.

A correspondent of the N. Y. Central Farmer gives the following statement of the nutritive qualities of the Flour of various countries:

I have noticed lately, some experiments which have been made in France, that seem to be important; at all events, they are interesting, and I think useful. The nutritive quality of flour has been ascertained by a French chemist, from a variety of samples which he has analysed, and the following is the result:

Nuremburgh bread is equivalent to	100.00
Dresden,	115.31
Berlin,	116.04
Canada flour,	117.23
Essex,	121.33
Glasgow unfermented bread,	123 15
Sothian flour,	134.06
U. S. flour,	145 03
U. S. flour by chemical analysis,	150.00

By this it will be seen that the U. S. flour is far the most nourishing of any in the world.

TO MAKE WATER COLD.

The following is a simple mode of rendering water almost as cold as ice:

Let the jar, pitcher, or vessel used for water, be surrounded with one or more folds of coarse cotton, to be constantly wet. The evaporation of the water will carry off the heat from the inside and reduce it to a freezing point. In India and other tropical regions, where ice cannot be procured, this is common. Let every mechanic or laborer have at his place of employment two pitchers thus provided, and with lids or covers; the one to contain water for drinking, the other for evaporation, and he can always have a supply of cold water in warm weather. Any person can test this by dipping a finger in water, and holding it in the air of a warm day; after doing this three or four times, he will find his finger uncomfortably cold.

Dr. Franklin recommends a young man, in the choice of a wife, to select from a *bunch*, giving as his reason that when there are many daughters, they improve each other, and from emulation acquire more accomplishments and know more, and do more, than a single child spoiled by paternal fondness.

The following article, on Farming in Connecticut, from the Albany Cultivator, will apply with equal force to many planters in Georgia:

FARMING IN CONNECTICUT.—Our friend "*Quercus*," after stating some of the difficulties and perplexities attendant on commencing farming operations on a soil which had been worn out by bad management, says:—"So the year has gone round—all the avails not counting 3 per cent. on any respectable estimate of the value of our 300 acres! This is not a fancy sketch. I can even count dozens in no better condition, from my window, now; but nine out of ten are mortgaged. None of their managers take the Cultivator, you may be sure. But how do they live? They sell a little wood, and burn coal, and live cheap, and buy nothing for money, and shoot foxes; starve their cattle and eat the carcass! But 'my man,' some bluff westerner wolud say, 'give away your land, (for I know it can't be sold,) and get you a bit of our unexhausted soil, and begin again.' It is the easiest thing in the world to give advice to those of whose circumstances you have no knowledge. Still if there were no circumstances in the way, I should be loth to think and act upon the thought, that a proper degree of energy and skill and foresight, will not spread fertility like a mantle, all over these rocky hills and these mossy meadows. Beside, there are attractions here--there are warm hill-sides in winter, and cool, rustling breezes in summer, and glorious old oak woods, and a hundred brawling brooks, (you may laugh if you have a mind to,) if the memory of their noisy prattle runs back to boyhood, call louder on a man than the yellowest mint-drops.

"At any rate, I will try what can be done to make my farm worthy of a history. If the resources which such men as Mr. James Johnston have opened to view, be not humbug; if the system of changing crops, of multiplying manures, of more effectual tillage, of adequate protection to cattle; it careful feeding be not wholly impracticable; if the history of your most successful croppings be not fairy tales, and the *locum in quo* a fairy land, why, *something shall be done here.* The progress of my trial, I shall open in scattering continuations of this history, neither exaggerating or concealing, in the hope that it may possibly be useful."

From the Mercantile Journal.

HEN'S EGGS.

We have received from a subscriber a couple of hen's eggs of immense size—being a specimen of the productions of a breed of hens brought into this country from Guilderland a few years since, by Capt. John Deveraux, of Marblehead. They weigh 3 oz. and 3-4 a piece, and measure 7 3-4 inches in circumference one way, and 6 1-2 the other. If any one has any larger hen's eggs, bring them along!

We learn that these Dutch fowls are of a large size, some weighing 7 pounds a piece, of a coal black color, may be easily fattened, are delicate food, and first rate layers. Their eggs are usually one-third larger than those of our ordinary fowls. One of the hens which Capt. Deveraux brought home, layed 160 eggs, daily, in succession!

From the Farmers' Cabinet.

THINGS THAT DO NOT LOOK WELL.

When I saw the substance of the following paragraphs in the Prairie Farmer, I felt more than half inclined to be out of humor with its editors. Parts of them touched me so closely, that I concluded at once, some of my neighbors had been to Chicago, and told of me, and had got the piece inserted just to vex me. Let, however, "him laugh who wins." Instead of being annoyed, though touched in a sore place, I have made up my mind, not only to try to reform myself in those particulars, but also to give others an opportunity to profit by them. Q.

It does not look well to let the garden grow up to weeds, and then say that a garden is good for nothing.

It does not look well to have the gate without hinges, held up by a prop, leaving at the bottom an aperture through which some hog, with a convenient nose, can rub, and so slip around into the garden.

It does not look well for a man to thump and abuse his horses or oxen, just to try his whip; or to suffer his boys to do so.

It does not look well to keep the horse in a stable not cleaned, till his hind feet are 45 degrees higher than his fore feet, so that he is obliged to rear up to get himself on a level every time he wishes to swallow a little hay or oats.

It does not look well to have the women hang out the clothes on rough and thorny bushes, and tear them in getting them off, when a neat line would save that trouble.

It does not look well for a man to keep a dog, when he can keep no cow or pig; and for no purpose but to worry the neighbors' cattle, and annoy the neighborhood with continual barking.

It does not look well for any body's daughters to walk the streets in kid slips in December, and lace themselves so cruelly that their voices waste away, and their cheeks turn to the color of moon-light.

From the Maine Farmer.

PATENT ENDLESS BEE-HIVE.

John Milholland and Benjamin Crane, of Chandlersville, Muskingham county, Ohio, have invented a new and useful improvement in the construction and use of the Bee-hive, for which they have obtained letters patent of the U. S. Government, bearing date the 29th day of April, 1842.

The nature of the invention is in constructing the Bee-house in horizontal, rectangular sections, or boxes without tops or bottoms, placed on a base,—supported by four spreading legs,—on which base is a double inclined bottom, for the discharge of all offensive matter. The sections are placed upon the base, and upon one another, until the house is raised to a sufficient height, and the upper box is covered with a horizontal top.

From the Farmers' Cabinet.

BEE MOTH.

Mr. Editor—In the last number of your Cabinet, you say that "on examining your bee-hives in the morning, you have been annoyed by frequently finding on their platform, worms full grown, which had no doubt been hatched from the egg of the bee moth. Where did they come from? Will some of our friends tell us?"

The bee moth is a nocturnal visiter, and enters the hive after the bees have retired to rest, and deposits its egg in the comb where the insect, when hatched, meets with its proper food, until it arrives at maturity. It then descends to the bench, and incloses itself by the web which it spins, and passes into the pupa or chrysalis state, before it becomes a fly. The moth-worms, which have lived through the winter, will commence leaving the comb the last of March and beginning of April, and continue to do so till late in May; by which time those that came first have become flies—ready to enter the hives and carry on their work of destruction. These insects pass through all their different changes, from the egg to the fly, during the hot months, in the course of five or six weeks. In 1838, I put some of these worms in a glass jar, on the 9th, 12th and 14th of April; the flies came out after the 23d of May. Few worms were found under the hives after this date.

To mitigate the ravages of the bee moth, I spread salt on the bench below the bee-hive, and keep it there from March to November. If the worm should descend when the salt is damp, it will be so far prostrated as seldom to recover; but if dry, it has very little effect. Frequent attention is still necessary to meet with success in the management of bees.

An Octogenarian.

Albermarle, Va., May 31, 1844.

From the N. E. Farmer.

IMPROVE THE BORDERS OF FIELDS.

Strips of land on the borders of fields, next to the wall or fence, where the plow could not be brought to work, are very often suffered to lie idle, and produce nothing. Now, if such strips were improved by planting bush beans or peas, or winter squashes, they would yield a product of more profit, I venture to say, taking into account the expense bestowed on them, than the same amount of land planted with the main crop of the field.

"Many a mickle makes a muckle," says the Scotch proverb; and a hill of beans here, and of squashes there, in spots which would not otherwise be occupied with any thing of value, will count up at harvest, and furnish a supply of these excellent vegetables for family use, sufficient, perhaps, for the whole winter.

This may seem to some a small matter; not so do I view it; it is an object worthy the farmer's attention. He certainly renders his reputation of being a good husbandman somewhat questionable, who suffers any portion of his land to lie idle, that could be just as well improved, and with an assurance of profit.

Many such unoccupied strips of land as those alluded to, might be put to a useful purpose, I think, in being planted with the sun-flower—the seeds of which, some maintain, are no less valuable for poultry than grain. If these seeds have such value, most certainly they would well repay for the expense incurred in raising them.

D.

From the Albany Cultivator.

BEES.

To stop bees from fighting and robbing one another, break the comb of the robbers so that the honey will run down among them, and they will go to work at home. I had two hives of bees destroyed this month by being robbed, and should have had another robbed, if I had not received the above information.

Substitute for Cream in Coffee.—Beat the white of an egg to a froth, put to it a small lump of butter, and turn the coffee to it gradually, so that it may not curdle. It is difficult to distinguish the taste from fresh cream.

Toothache.—The London Medical Gazette states that the *Fepeta cataria* of Linnæus is recommended by Dr. Gaustamacchia as a sovereign remedy for toothache, whether it proceeds from catching cold or caries. The leaves of the plant are placed between the affected tooth and the opposite one; this causes a copious flow of saliva, and in two or three minutes the mos violent pains are relieved. If the patients cannot keep the leaves in contact with the diseased tooth, they must chew them, and the object is equally attained by a flow of saliva thus incited.

Croton Water.—The length of pipes laid down in the city of New York for distributing the Croton water is 150 miles. The amount of water rents realised for the year ending 1st May, 1844, was $92,626. The water is used by 4932 private dwellings, which pay from $5 to $25 per annum; the average rate per annum, for dwellings, is $12. The number of steam engines, stables, bathing houses, &c., &c., supplied with water is 1987. There are 600 free hydrants, and 1500 fire hydrants.

A Singular Case.---A Mr. Hewett died lately in Ohio with the mumps, followed by erysipelas, which affected his brain. In his delirium he injured two persons; one received a slight abrasion on the hand which was followed by an alarming swelling---another received a blow on the eye brow, which was followed by swelling and derangement. He grasped his mother's hand so tightly as to stick his nails in her flesh—the hand became inflamed, the arm swelled to the shoulder, with livid spots, and she died.

TURNEP SEED.

A SUPPLY of the following varieties of fresh TURNEP SEED just received, viz:

Yellow Sweedish or Ruta Baga, very fine for stock,

Large Globe Turnep, } Fine
" White Flat do. } for
" Hanover or White Ruta Baga do } table
" Norfolk do. } use.

For sale in quantities to suit purchasers, by
Aug. 30 18-tf WM. HAINES, Jr.

GARDEN AND FIELD SEED.

A GENERAL assortment of fresh and genuine GARDEN and FIELD SEED, among which are the following:

Red and White Clover,
Blue and Green Grass,
Rye and Orchard do.,
Timothy and Herds do.,
Millet and Lucerne do.,
Seed Corn of every valuable variety,
Seed Wheat,
Buckwheat and Potato Oats,

Kept constantly on hand by the subscriber, all of which are offered for sale at very moderate prices. All orders, by mail or otherwise, executed with neatness and despatch.

ORIGINAL COMMUNICATIONS.

For the Southern Cultivator.

OVERCROPPING.

MR. EDITOR—Since you have published my first essay, I shall try again. Your readers, no doubt, felt alarmed when the destruction of lands at the South was attributed to so many causes, for fear all the subjects would be treated at once: they were relieved when the last subject was commenced first, just as we commence plowing a field on the far side first, and finish at the gate; so that we may not have to pass over the plowed ground, but have it all smooth and even. If my subjects are not treated as your regular writers and book-makers do theirs, (for I do not profess to understand their arts,) I shall drive on steady as we do when plowing, and try to do my work well.

The next subject to improper implements of tillage, was over-cropping, or planting more than can be cultivated in a proper manner. My brother farmers often remind me of the child, to whom Dr. Franklin continued to give apples, and who, in trying to hold all that were given to him, let fall nearly all he had received. We are all children of a larger growth, in our dispositions, and often lose what we have, by reaching after more than we can hold. And, by attempting to cultivate too much land, we make less than if we had cultivated a smaller quantity in a neater and better manner. If the farmers can be convinced, that they can raise more produce on less land, and with less labor, it will be their interest to try the experiment. There is a pleasure, a beauty, and independence in farming, which no other calling or profession can claim: by over-cropping, all these are sacrificed. Everything has to be done in the roughest manner; the grain is planted when the ground is only half prepared to receive it. Over-cropping necessarily leads to over-tasking; requiring more of the working hands than they can perform well. They become careless, slight their work, and injure the growing crop. The hands become prematurely old and decrepid, the horses and mules are soon reduced to poverty, and are able to perform only half work; the lands become less productive every year, making it appear necessary to plant more, in order to produce a given quantity. Such a system, if continued, will lead to utter ruin in the end; or compel a man finally to abandon his home and his country, and remove to the "far west."

A farmer should not make his calculations for one year only, but should look forward to the end of several years to future profit. We cannot become suddenly rich; and, if we can make a support, and improve our lands, our stock, &c., and gradually increase in wealth, or even hold our own in such times as the present, we shall be doing well. Many men have failed from too great an anxiety to get rich quick, not being willing to wait and content themselves with small and regular profits. After making a plentiful supply of all kinds of provisions, and making all the clothing necessary for his family; raising his horses and mules, and raising a number of sheep equal to the whole number of his family, white and black; then every farmer should plant as much cotton every year, as he can cultivate neatly, and no more. Facts and well attested experiments alone, can convince most of the farmers, and often the experiments have to be tried by each one individually, before he is satisfied with the result. Let every farmer in the State, then, manure such a sized piece of land as his means will allow—say one acre, or five or ten acres—prepare it well, and plant it at the proper time, in corn or cotton; cultivate neatly, and measure or weigh the production, and then make a calculation for a number of such acres sufficient for his force, and he will at once see the difference between such cropping, and skinning over a farm, and wearing it out. If as much can be made from one manured acre, as from three unmanured acres, it will be less labor to cultivate one acre than three, and then the one acre is ready manured for the next year's crop. But I already hear them say, "What does one acre prove? We may manure one acre, but that proves nothing, because we can never find manure enough for one-tenth part of our whole farms." Manuring a plantation is a new and untried business to most of the Southern farmers, who generally have found barely enough manure for their gardens. All science is progressive; we cannot expect to reach perfection at the first or even second attempts—but, by perseverance, we may leave our children with more knowledge of agriculture than we commenced with. Some men are now living who recollect when cotton was thinned with hands, the open bolls pulled and carried into the house, and there picked out, and then the seed separated from the cotton with the fingers. Who would have thought, then, that a hand now would be able to make five bags of cotton in one year? Some years ago, it consumed three or four month's of time to cross the Atlantic ocean, now it is crossed in 12 or 15 days. It once took 3 or 4 weeks to go from Georgia to New York; it is now travelled in 3½ days. And so of equal improvements in many other arts and sciences. Some whole countries are highly manured, that were once as barren as the worn-out fields of Georgia. Shall we despair of improving our farms, in sight of such vast improvements? Shall we sit still, and acknowledge ourselves less energetic, less active, and less enterprising, than other people and other professions. The intellect of the South has always compared favorably with other sections of the country. Let us, then, not despair. If one acre can be made to yield as much as three acres, one hundred acres, by the same process, may be made to produce as much as three hundred acres. The sum can be worked by the rule of three; and, while they are all cyphering it out, I will tell them where and how we can get, at least, some of the manure, which will obviate the apparent necessity for over-cropping.

Yours, &c., PLOWMAN.

For the Southern Cultivator.

EXTRACT.

Imagine the greatest General, after the most glorious victory recorded in history, the dead, wounded and dying, the widow's lamentations, and the orphan's tears, and the amount of misery inflicted upon the human race, in consequence thereof.—Imagine the wily politician, urging his tortuous way to high office, covered with the mantle of private friendships broken, with hypocrisy, cunning and corruption.—Imagine the scientific agriculturist, directing, encouraging, counselling and assisting his co-laborers in the management of their farms, until the whole State shall attain the highest degree of agricultural improvement, "The fields shall blossom as the rose," and peace, happiness and abundance, shall bless the land.

Which is the greatest benefactor to mankind? which most likely to receive the approbation of Divine Providence? PHILOS.

For the Southern Cultivator.

MINERVA, GA., 4th July, 1844.

MR. EDITOR—With a few honorable exceptions, I see that most of the original communications in your very useful paper, contain no failures of crops, but a series of the most successful plans and efforts, with the greatest amount of production per acre. At a very slight glance, all this would appear unexceptionable. But I am compelled to believe, these authors of original communications have succeeded far beyond anything which comes within the reach of my experience—or else they have given us the bright side of the picture to admire, while they keep the other side in the dark. I wish, for the general good of agriculturists, that these gentlemen would deal fairly with us (your readers) upon the broad principle of their systems, and be particular in giving us, in detail, their account of failures, as well as success. Such a mode of procedure would accomplish more in setting us on the right plan, than any partial description which gives a very high coloring only to a part of their mode of agriculture, while nothing is said concerning, perhaps, nine-tenths of the general system. The moralist may lecture me a month on the evils of intemperance, and the good effects of a life of virtue, without producing much effect. But when I behold the drunkard in rags, wallowing in filth, my senses are struck with his degraded condition in the keenest manner; I am in a moment convinced of his error by contrast. Not so with these gentlemen farmers; all their deductions are specimens of perfection—they give us one side of the picture only, and we have no foundation afforded us by them, of the good and the bad plans by which to form the contrast. It is by contrasting a bad and ruinous course of husbandry with a good one, that we are enabled to see the beauties, and appreciate the advantages of the latter. And, as I have some considerable more experience in a ruinous system of planting than any other, and also as an offset to the other communications, for the purpose of a contrast, I propose to offer—

The way to make a light crop of corn.—March,

1843, in farmer's language, I ridged up fifty acres of lime, or prairie land, part of which had been in cultivation for fifteen years, the other part nine years. On the 15th of March, I planted the corn five feet one way and three feet the other; at the same time I put into the hills one handful of well-rotted cotton seed as manure. In consequence of the *raw* condition of the land, I got a bad stand. Two stalks were left in the hill. After the corn was fairly up, I plowed and hoed it over. I plowed the corn over (with what is common in Georgia, Turner plows,) four times, and each time the plow sunk very deep. But unfortunately for the crop, and myself too, the first or breaking up plowing was done at a very dry time, and consequently it turned over in large clods, which never became pulverized the whole summer. This last is a very remarkable circumstance, but no less remarkable than true. The third time it was plowed, it was up to the shoulders of a common-sized man: previous to this plowing, the corn was rather likely. But in two days after the third time the plow ran through it, close and deep, (for I thought there was nothing better than deep plowing,) *it fired.* [The last two words may appear very awkward to an editor—but, my word for it, the readers of the Cultivator will understand, by them, the exact meaning I wish to convey.] During this plowing, the weather was hot and dry, and continued so till the corn *fired* up to the tassel—and had there been any blades above the tassel, I have no doubt but they would have shared in the same fatal blast. It will be remembered that it was the third plowing which produced this bad effect. This state of things brought me to a perfect stand still. Thinks I, to myself, what shall I do—my corn is *fired all over?* Is there no remedy? Ultimately I adopted a vulgar and foolish conclusion, viz: "a piece of the same dog will cure his poison," and I gave it another, which made the fourth deep plowing! In all conscience, I soon found this was sufficient. I gathered about ten bushels of *nubbins* per acre—was not very particular about the measurement, for I have no fears that any of my brother farmers will be the least disposed to discredit my report, as they are all, to a man of them, convinced that this thing of *nicely* measuring nubbins, is by no means a profitable or pleasant job.

This is an accurate and faithful description of the whole process; one, too, which experience teaches me will be certain to *make a light crop of corn.* I had planted the same land in corn for a number of years previous; and, with a *loose system* of cultivation, common all over our country, I made, in the general, about 20 bushels per acre. I attribute the failure of the crop to the following causes:

1st. From what I have seen, four times is too often to plow corn.

2d. One, instead of two stalks, should have been left in the hill.

3d. The subsoil of the land is a stiff clay in part, and a calcareous marl on another portion of the field, which requires the breaking up to be done during the winter, for reasons sufficiently obvious to any planter.

4th. From the want of this early breaking and pulverizing, the perpendicular or straight roots were prevented extending down and seeking their due quantity of nourishment, and the horizontal or side roots were all torn, and so lacerated by the close deep plowing, the two last times, that they were utterly incapable of performing their function—that is, of assimilating and carrying nourishment to the stalks. All of us know, when the doctor salivates us, what an awful situation our mouths are placed in—and precisely so it is when the roots (mouths) of a plant are torn and lacerated by bad cultivation. It is impossible to take nourishment.

D. B.

☞ A lead mine has been discovered on the Ilinois shore of the Ohio river about 30 miles above the mouth of the Cumberland river. The ore is said to contain a larger quantity of silver than any lead ore yet mined in this country.

For the Southern Cultivator.

HUMBUGS.

The word humbug is of such frequent use, and so unreservedly bestowed upon every new enterprise of late, that a definition becomes unnecessary. Any thing new, whether it be a principle in politics, service in religion, or in the form of a new variety of seed, is apt to be seized upon with interest, and looked upon either as promising liberty in its purest form, piety without self-denial, or an abundant crop without labor. Thus, under a sort of romantic excitement, we recommend without caution, and promise without limit, until expectation is raised so high that it is impossible it should be realized when brought to the test of practical life. Those, therefore, who had been indulging in golden dreams, under the mortification of disappointment, denounce as a humbug what they once enthusiastically recommended.

This is one reason why things, which are really useful, have been denounced as humbugs. Persons making the first experiments, speak *too freely* of qualities they merely know from hearsay, and promise *too much* not to disappoint: so that, in our anxiety to become well supplied, as soon as possible, with whatever promises so great a reward, we save *every seed* from our first crop—every pig from our first Berkshire, or every calf from our fine cow, without any reference to the maturity of the first, or strength of constitution, or symmetry of form in the two last. The consequence is, that the imperfect seed produce imperfect plants, which impart their weakness to others, and the seed rapidly degenerate: so that, about the third year, when we have a sufficiency for a full crop, we find it so much deteriorated that we pronounce it a humbug, throw it aside, and not unfrequently with the rash promise that we will, in future, have nothing to do with any "new-fangled notion;" which promise, however, is broken upon the first temptation.

The same might be said of stock, with equal or greater propriety. The anxiety to get in stock as soon as possible, leads us to breed from every animal, however defective in form, until the whole perfection of the improvement is lost by impatience and avarice. This position may be illustrated by the Berkshires, which have become common, and are frequently pointed out as one of the humbugs of the day.

But, as I set out with more direct reference to seeds, and especially wheat, I will not pursue this part of the subject. The time has arrived when farmers should be selecting their seed for the next crops: and as this is, ere long, to be a more important branch of Southern agriculture, it is time that we were paying more attention to the subject, especially in middle and upper Georgia. I have no doubt that if more care were taken in the selection of seed, together with greater care in preparation for the crop, and the seed sowed early, our wheat crop, which has hitherto been looked upon as the most uncertain, and promising the least return, would not only be as certain as any other crop, but probably the most profitable.

Mr. Ellsworth, in his able and interesting report for 1843, under the head of "Selection of Proper Seed," recommends that, in saving seed wheat, a large seive be used, which will allow five out of six bushels to pass through, and the remaining bushel only to be saved. Thus, the finest and most perfect grains are used, from which we may as reasonably expect a crop of a like kind, as we would look for a fine pig from a sow of fine parts. If this course were pursued with new varieties of seed, we would not so often see the best kinds thrown aside as humbugs, but might expect a more rapid improvement in our agriculture.

WALTON.

P. S.—I noticed in a number of the Cultivator, either of December or January last, a request that you would publish a simple mode of analysing soils; and, in your last, I see a short mode described. If you will hunt among your old files of the Georgia Journal, you will find a very simple mode at greater length, published about April 21st, 1840.

We have no file of the Journal, and should feel obliged to our correspondent for a copy of the analysis referred to.—ED. S. CULT.

For the Southern Cultivator.

MR. EDITOR—With much delight I see, in the last No. of the Southern Cultivator, that the subject of overseers is now undergoing a careful investigation. I have been long since of the opinion, that no subject, connected with the planting interest in the Southern States, needs a more careful review and radical change, than the loose and careless system of overseeing everywhere so prevalent. And what is still more strange to me, planters, otherwise well informed, operating, too, with a large capital, are annually employing men for overseers, who have no more scientific skill in the business of successful husbandry, than they have in directing a ship right in a whirlwind. Nay, more; perhaps one half of these submit the whole process entirely and exclusively to the care and management of these tyros! This is the great reason why the sound of indebtedness is heard to grate so heavily upon the ears of so many planters. Some are engaged in the discharge of the arduous duties of a profession, while others, perhaps, are promenading the pleasant walks or batteries of Saratoga, Limestone Springs, etc.

Why, Mr. Editor, these gentlemen have certainly, like "Old Rip Van Winkle," slumbered long enough. Upon what reasonable foundation can they build a hope of seeing, upon their return to the plantation, green pastures, and fields laden with the riches of the earth? I am but a novice in the art myself; but I can prove my position correct when I state that it is a problem of no easy solution, to adapt the different manures in our reach to the many and various soils in the Southern States, with the best mode of preparing the land, time of planting, tools best adapted to the whole process of culture, &c.; and again, the most economical mode of feeding and raising the farm stock. I hope the ball on this subject is started, and the wise heads of our citizens will handle it with "naked hands," expose error, and set us right upon such a momentous subject.

D. B.

The Bull and Locomotive.—The daring character of an infuriated bull is well known and attested in many singular encounters. A bull near Gray's Ferry on the Schuylkill, was frequently annoyed by the noise and fiery appearance of the locomotive and train, which daily passed his grazing ground. At length he determined to take the matter in hand. So waiting the appearance of the locomotive, which came hissing along the road at full speed, the bull gathered himself up for the rencounter, made a fearful dash, full tilt, with his horns at the engine. The concussion threw the whole train off the track on Sunday, June 7, delaying the arrival several hours beyond the time. The poor bull, of course met with his *quietus* very suddenly—having been cruelly mangled and killed at the very onset.

☞ A remarkable fact is stated of the chickens hatched by the machine in New York, that they are *several ounces* heavier than the egg was at first. Is this the case with all chickens?

SELECTIONS, EXTRACTS, &c.

OBSERVATIONS

On the Action of Calcareous Manures, and their Practical Application and Effects.

Previous to the commencement of my examination of the marls of South Carolina, there had been but very few attempts to profit by their application as manure. It would be both a needless and ungrateful task to inquire into the causes of this strange and general neglect of such wide-spread and easily available resources for fertility and riches—and of disregard and ignorance of truths generally known and acted upon in other regions far less blessed in these resources, and in the capability of profiting by their use, than lower South Carolina. It is enough here to state, that such was the general neglect of calcareous manures, and general want of efficient information as to their value. Many individuals, indeed, had made very small and mostly improper applications of marl, and a few of lime, and which were as loose and inaccurate as experiments, as they were ill-directed to obtain the best results as manure. And a few individuals presented more marked and meritorious exceptions, in having within the last few years made much larger applications, and having reaped more or less appreciable and admitted profits therefrom. Among these, the oldest or the largest operators, and, as they deemed themselves, also successful marlers, besides those already mentioned, were Mr. Darby, of Orangeburgh, Dr. J. S. Palmer, and Col. S. J. Palmer, of Charleston district, Dr. Robert Gourdin, of Georgetown district, and Gen. Jas. H. Hammond, of Silver Bluff, Barnwell. Reports of the applications of the four last named gentlemen have been recently published, and their favorable results stated. But the total amount of these, added to all other applications of marl and lime made in South Carolina previously to 1843, it is believed, fell short of 500 acres. It would furnish an interesting and most useful statistical document, if the Legislature would hereafter require the extent of each planter's applications of marl and lime, for every successive year, to be ascertained and recorded by the tax collectors; and, a few years hence, also the then and thereafter estimated increased product of the improvements thereby made. Such statements, continued and published regularly year after year, would exhibit an amount of newly directed labor, and of newly created agricultural wealth, beyond any present conception of the effects; and the exhibition would stimulate the further exertion and increase more than any other possible mode of conveying instruction, or of urging the propriety and profit of using calcareous manures. Nearly all of the few applications of marl, or of lime, which have heretofore been made, have failed of early or satisfactory effect, or for so long as observed for effects, because of the improper mode of application; which was, as usual with putrescent manures, by burying the marl under the "list," and thereby avoiding, and indeed *preventing* all intermixture of the manure with the soil, which is essential to its operation.

Considering the great variations and degrees of fertility of cultivated soils, and the important bearing of such differences on the profits of the cultivators, it is strange that so little attention has been given to the causes, or of care to avoid the worst and obtain the best effects. Every proprietor knows that the profit of cultivation is much greater on rich than on poor ground. But very few have estimated *how much* greater is the profit; and nowhere, within the sphere of my observation, are the prices of lands properly graduated, in proportion to their fertility and true productive value. If properly estimated, it would be manifest that poor land, for cultivation, if to remain poor, would be dear as a gift, and its cultivation the most costly of all. Yet, the greater number of cultivators of such soils, are content to remain in that condition, without making an effort, and scarcely indulging a hope of improving their fields and their profits.

It is not the less remarkable, that the more sanguine and enterprising cultivators, who aim and hope to improve, seldom inquire into the causes and manner of the operation designed, and therefore, most naturally, seldom succeed in their design. To apply the ordinary putrescent manure, is generally the sole means attempted or thought of; and if on poor and bad soils, in the race between exhaustion and new fertilization, the latter is invariably left far behind.

It is a universally acknowledged truth, that what is needed to make soil most productive, are such ingredients as will supply, in sufficient abundance, the *food of plants*. Growing plants draw from the soil by their roots, and are nourished by the dissolved parts of nearly all putrescent matters, either vegetable or animal, or mixtures of both. The ordinary manures are precisely such substances; and sooner or later, by their gradual decomposition, are converted almost entirely to the food for plants, and if judiciously applied, are consumed by, and help to sustain, the growing crops.

But it is not enough, by a great deal, that manures serving to form food for plants, shall be given to the soil. There are other conditions necessary for their profitable and best effects; and the most important of these conditions is, that the soil shall be so constituted as to preserve the putrescent matters from waste and profitless dissipation, and to give them wholly for the support and growth of plants. This condition is furnished by nature, in well-constituted soils only, which present the most productive and durable lands under tillage. Without this constitution, all the supplies of putrescent manures which can be given to a farm, will be of little profit; and if derived from its own resources only, will be utterly insufficient to preserve, and still less to increase, the yearly measure of productiveness of the land.—*Ruffin's Agricultural Survey of South Carolina.*

From the Maine Farmer.

RUTA BAGA AS FOOD FOR CATTLE.

Mr. Holmes:—I see by your remarks in the last Farmer, that the merits of the Ruta Baga have been called in question, and that it has already fallen from the high estimation in which it was once held, and is now but little cultivated. Of the evidence upon which it has been condemned, as unprofitable, you have not given us any account. Yet there may be sufficient reason for not cultivating it very extensively, without practicing the old proverb that, "when one is found going down hill, every one must give him a push." Much of its favor has arisen from the great fondness which has been manifested for it, by cattle. They are not, however, more fond of the Ruta Baga than of most other succulent food, which is very naturally accounted for, as all the juices are retained in addition to the organic matter which it contains, and is fed to cattle at a time of year when they are confined exclusively to dry fodder. This, I think, must account for the fondness of cattle for Ruta Baga, rather than for any extraordinary nourishing qualities which it may possess, as apples, potatoes and beets, and any other succulent food, given them in the winter season, is devoured with equal avidity as turneps. It has been found, by chemists, that about nine parts in ten of turneps, are water, while most other vegetables of the grain kind average nearly reversed proportions of water and organic matters, containing about fifteen or eighteen parts of water, and eighty-five of organic matters. This, certainly, is fair evidence against turneps, that is, if Liebig knows any thing.

Another item in the indictment is, that the ground has to be made richer for their growth than for any other crop that is produced, and is left in a poorer condition for a succeeding crop than by any other vegetable. This fact I know not how to account for, but experience has proved it to be so. In some cases, but little more than half the grass is obtained from land occupied by turneps the previous year, that will grow on land that has been planted to corn or potatoes, with the same manuring.

Turneps, when fed to cattle, operate in some way to produce a powerful appetite, and this causes them to eat a larger quantity of fodder of the coarser kind, it required, and in this way they are kept in tolerable good condition upon comparatively poor fare. In this, principally, lies the philosophy of cattle thriving as well on poor hay with a few turneps, as they will when kept on good hay, without any turneps. G.

Winthrop, June, 1844.

From the American Agriculturist.

SHOW OF THE AGRICULTURAL, HORTICULTURAL, AND BOTANICAL SOCIETY OF JEFFERSON COLLEGE.

I sit down to give you a brief report of our Spring Agricultural Show, which came off yesterday. We have had a very interesting meeting, and the attendance, all things considered, was very full indeed. Several other calls of interest occurred, unavoidably, on the same day, in our neighborhood, drawing off a great many; and the roads are insufferably dusty, from the long, severe and ruinous drought we have had, and still have. Nevertheless, *we who do the work* have great cause of complaint to make, that on a subject of such vital importance to their interests, as *improvement in all things agricultural*, planters show so much apathy. On the occasion of a very interesting trial of the comparative merits of a number of agricultural implements, which occupied a committee appointed for the purpose, during two hours in the morning, there were but some fifteen or twenty planters on the ground! But, from the many expressions of regret, which I have since heard, for non-attendance, when it became known how much of exceeding interest they had missed, I am confident that at the October trial we shall have *a crowd*. It is upon this part of the exhibition that I have most to say, as my time and attention, during the day, were too much taken up to give the stock and other things more than a cursory glance. I will forward you papers with the reports of committees at length, and pass on with the remark, that the number of cattle and horses was, I thought, fully as great as at any previous meeting, some of them being remarkably fine.

Of bulls, Mr. Hall had a very handsome two year old white bull, which, in my estimation, rated first; he is a compact, well-made animal, and *handles* well. Col. D. Cooper, from Wilkinson county, exhibited an aged bull which I must place next, even over the head of Mr. Hall's mountain of beef, Beltzhover: in my opinion, there is no comparison between the two animals, though I know that I could find few here to side with me. There were also two younger bulls, the property of Samuel Chamberlain and D. P. Jackson, that were very fine.

Of sheep and hogs, the show was a poor one; every one being, like myself, afraid of the excessive dust. Col. Wailes exhibited a pen of very good sheep. In vegetables and flowers, too, we were sadly wanting—caused by our long drought. Col. Wailes, the Rev. Mr. Whielden, and Dr. Butterfield, occupied one of the college halls with their fine cabinets of stones, minerals, fossils, &c. Col. W. has a most valuable collection, particularly of agates, madrepores, cornelians, &c., and of fossil and Indian remains. Mr. Whielden exhibited a miniature cage, of broom-straw, in which were some dozen silk worms in the act of enveloping themselves in their silken covering—by them lay a number of others, in different stages of growth, feeding.

But to the implements. At about nine o'clock, the committee commenced operations on a piece of ground here, on Ingleside. From the printed report, you will see what plows, &c., were on the ground, and also the opinion of the committee, which you would oblige many here by publishing,† and confer, too, a more extensive benefit upon the makers of such things, if they will act upon it as they ought to do, than they are probably aware of. From the opinions there given, I must beg leave to differ somewhat. The fact is, we know so little here of how implements of cast-iron answer the purpose, that there is a strong prejudice against

them, which, however, would quickly give way to conviction. Ruggles, Nourse & Mason's plow, is a very large and heavy implement,‡ my objection to which I will give presently. It turned over a regular furrow of from 12 to 13 inches, by 6½ inches; while the two others that were tried turned only about 8 to 9, by from 4 to 7 inches. In my opinion the teams *did not* exert themselves more with the eagle plow than with the others, and the hand had not half the work to do—then see the difference in the amount of work done. The ground was very dry, and had been much trodden, yet the eagle plow laid it neatly over, covering up the weeds completely, and leaving the ground well pulverized, and ready for any kind of crop; while the other plows ran very unsteadily, giving the plowman much to do, and turning over a very irregular furrow, throwing up the ground in large clods, gouging them out, as it were. Wood's plow has been many years in use here, and gives universal satisfaction, doing excellent work when the ground is in fair order; and they are light, strong and cheap, costing $6, to 7 and $8. But when brought beside this excellent Boston plow of Ruggles, Nourse & Mason's, it was completely left behind, so much so, as to open the eyes of all present. One of the committee remarked, that though he had been a farmer all his life, he had learned more of plows and plowing during these two hours than he ever knew before! There is no necessity for our plows and other implements being so strong and heavy as with you—we have no stones. Then our teams are lighter—the weather greatly hotter, so that animals cannot stand so much. We are almost all too short of team, and of consequence have, at times, to work them too many hours. But I will go more at length into this matter in an article I have nearly ready for you, on *Implements for the South*, with rough sketches of some of my improvements. Our plows, however, want *length* to give them *steadiness*.

Let Ruggles, Nourse & Mason, and others of your best makers, including Prouty & Mears, and Barnaby & Mooer, send to our Fall Show some plows made for the South, and such as they can furnish us with here at fair rates, (my side-hill plow cost me here $18,50, Ruggles & Co.'s, with coulter and wheel, $13,) and they will open up for themselves a good market. We are tired of sending for implements without first seeing them. If they will forward them from Boston, they will come to the society free of charge, (see report.) Let them consign them to Wm. I. Minor, Esq., our President, and have them reach us by the middle of October, and they shall all have a fair trial, and will afterward be sold by the society, and the money remitted to the owners, or disposed of otherwise as may be ordered. Is there no possibility of sending us a correct dynamometer at the same time? If there is, let me know the cost, and the society, or some of its members will remit you in time to send us one.

If the owners of the plows so desire it, they will be forwarded to Shows in the adjoining counties of Jefferson and Wilkinson, and exhibited there also.

THOMAS AFFLECK.

Ingleside, Miss., 27th April, 1844.

‡Since the reception of this report, we have forwarded Mr. A. smaller plows of Ruggles, Nourse & Mason's manufacture, which we are certain will please him, for a single mule can draw with ease the smallest one we sent.—ED.

MODE OF APPLYING GUANO.

Having prepared the accompanying directions for using Guano, for the information of Sir Charles Lemon's tenantry, it has occurred to me that their publication may be of service to others:

1. It should never be applied in contact with seeds, as it kills them as soon as they begin to vegetate.

2. It should be mixed as equally as possible, with about four times its bulk of finely pulverized earth, or peat-ashes, (cold.) If sand is used, about twice its bulk will be sufficient.

3. The quantity per acre may vary from two to four cwt., according to the nature and quality of the land. Recent experiments have shown that a quantity which proved highly beneficial in poor soil, became deleterious upon land previously rich.

4. The best time for applying it is shortly after vegetation has commenced, and immediately before rain, or during damp warm weather.

5. The best mode of application is, to divide the quantity per acre into two or three equal parts, and sow them broadcast at intervals of about ten days, or a fortnight.

6. For small allotments it may be more convenient to use it in a liquid state—in which case, mix 4 lbs. of guano with 12 gallons of water, and let it stand for 24 hours before being used. The same guano will do for mixing again with the same quantity of water, after the first is drawn off.—*W. B. Booth, in London Gard. Chronicle.*

AGRICULTURE IN THE UNITED STATES.

In this country, where land is cheap, and the disposition of the people pacific, everything invites to the arts of agriculture, of gardening and domestic architecture. Public gardens, on the scale of such plantations in Europe and Asia, are now unknown to us. There is no feature of the old countries that more agreeably and newly strikes the American, than the beautiful gardens of Europe—such as the Boboli in Florence, the Villa Borghese in Rome, the Villa d'Este in Tivoli; works easily imitated here, and which might well make the land dear to the citizen, and inflame patriotism. It is the fine art which is left for us, now that sculpture, and painting, and religious and civil architecture have become effete, and have passed into second childhood. We have twenty degrees of latitude wherein to choose a seat, and the new modes of travelling enlarge the opportunity of selection, by making it easy to cultivate very distant tracts, and yet remain in strict intercourse with the centre of trade and population. And the whole force of all the arts goes to facilitate the decoration of lands and dwellings. A garden has this advantage, it makes you indifferent where you live. A well laid garden makes the face of the country about you of no account; low or high, grand or mean, you have made a beautiful abode worthy of man. If the landscape is pleasing, the garden shows it—if tame, it excludes it. A little grove, which any farmer can find, or cause to grow near his house, will, in a few years, so fill the eye and mind of the inhabitant, as to make cataracts and chains of mountains quite unnecessary to his scenery; and he is so contented with his alleys, woodlands, orchards, and river, that Niagara, and the North of the White Hills, and Nantaske Beach, are superfluities. And yet the selection of a fit house-lot has the same advantage over an indifferent one, as the selection of a given employment of a man who has a genius for that work. In the last case, all the culture of years will never make the most painstaking scholar his equal; no more will gardening give the advantage of a happy site to a house in a hole or on a pinnacle. "God Almighty first planted a garden," says Lord Bacon, "and it is the purest of human pleasures. It is the greatest refreshment to the spirits of man, without which, buildings and palaces are but gross handyworks; and a man shall ever see that when ages grow to civility and elegancy, men come to build stately, sooner than to garden finely, as if gardening were the greater perfection."

Bacon has followed up this sentiment in his two essays on *Buildings* and on *Gardens*, with many pleasing details on the decoration of lands; and Aubrey has given us an engaging account of the manner in which Bacon finished his own manor at Gorhambury.

In America, we have hitherto little to boast in this kind. The cities continually drain the country of the best part of its population: the flower of the youth, of both sexes, goes into the towns, and the country is cultivated by so much inferior class. The land—travel a whole day together—looks poverty stricken, and the buildings plain and poor. In Europe, where society has an aristocratic structure, the land is full of men of the best stock, and the best culture, whose interest and pride it is to remain half the year on their estates, and to fill them with every convenience and ornament. Of course these make model farms, and model architecture, and are a constant education to the eye of the surrounding population.

Whatever events in progress shall go to disgust men with cities, and infuse into them the passion for country life, and country pleasures, will render a prodigious service to the whole face of this continent, and will further the most poetic of all the occupations of real life—the bringing out by art the native but hidden graces of the landscape.

I look on such improvements, also, as directly tending to endear the land to the inhabitant, and give him whatever is valuable in local attachment. Any relation to the land, the habit of tilling it or mining it, or even hunting on it, generates the feeling of patriotism. He who keeps shop on it, or he who merely uses it as a support to his desk and ledger, or to his manufactory, values it very little. The vast majority of the people of this country live by the land, and carry its quality in their manners and opinions. We in the Atlantic States, by position, have been commercial, and have, as I said, imbibed easily an European culture. Luckily for us, now, that steam has narrowed the Atlantic to a strait, the nervous, rocky West, is intruding a new and continental element into the national mind, and we shall yet have an American genius. How much better when the whole land is a garden, and the people have grown up in the bowers of a paradise? Without looking, then, to those extraordinary social influences which are now acting in precisely this direction, but only at what is inevitable doing around us, I think we must regard the land as a commanding and increasing power on the American citizen—the sanative and Americanizing influence, which promises to disclose new powers for ages to come.—*R. W. Emerson's Lecture.*

From the American Farmer.

GREAT YIELD OF WHEAT.

We are indebted to Major H. Capron, of the Laurel Factory, Prince George's County, Md., for the subjoined letter, giving the result of his successful culture of "*worn-out fields*," and of his having raised at the rate of 43 bushels of Mediterranean Wheat, per acre, on land which five years ago would not have yielded 7 bushels of oats per acre. Major C. has sent us a sample of it, which looks plump enough to weigh well, and we should think would come up to the standard weight. Of this, however, we cannot speak with certainty, and should therefore thank Major C. to measure a bushel and inform us of its weight; and while he may be complying with this request, we trust that he will advise us of the successful method he pursued to bring up his "*worn-out old fields*" from the capacity of yielding 7 bushels of oats to the acre, to that of producing 43 bushels of good wheat; and here we would have him to believe us when we declare, that he could not address a more "desirable" paper to the agricultural community than such an one would prove. In all the old States, there are thousands and tens of thousands of just such lands as he has described, which do not now produce enough to pay the cost of interest, taxes and tillage, much less to afford a profit—and if these can be brought up, by any process moderately costly, to produce only half what his "old fields" have yielded, an end will at once be put to emigration, that bane of the old States, which, for years, have been draining them of much of their capital, enterprise, skill and industry; and in so doing he will prove himself a real benefactor—a benefactor whose good deeds will live as long as memory or history serves to transmit the incidents of one generation to another.

The sample of this productive wheat which we have received, we consider *in trust* for distri-

bution, and shall be happy to divide it among our patrons.

—

Laurel Factory, June 24th, 1844.

To the Editor of the American Farmer:

Sir,—I send you a sample of Mediterranean Wheat, grown upon a field of about 26 acres; which, five years ago, would not have brought 7 bushels of oats per acre. I cut this wheat on the 12th of this month, and thrashed it out on the 21st. I measured a piece as an average of the whole field of 133 yards by 39 yards—containing 1 11-160 acres. The product, as ascertained by three disinterested witnesses, was 46½ bushels or about 43 bushels per acre.

This demonstrates pretty clearly, I think, the practicability of improving these "worn-out old fields." The art of renovating these kind of lands I may give at some future time, should you consider it desirable.

Yours very truly, H. Capron.

From the Massachusetts Plowman.

THE SEASON FOR TRIMMING TREES.

As soon as planting is over, we should look to our apple trees and cut off the surplus branches. We cannot recommend cutting large branches in any case; we usually do more hurt than good when we take off a limb that is more than two inches in diameter, for the wound will not often heal soon enough to prevent decay at the heart. A tree will sometimes look more thriftily, for a time, in consequence of lopping large branches, but the improvement will not be lasting. If trees are attended to annually, there will be no need of cutting large limbs. If they have been long neglected, we should content ourselves with trimming out the small limbs, and suffer the tree to continue in the shape that it has already formed.

We may not be able to give any satisfactory reason for preferring May to March, for trimming apple trees. Most farmers, however, agree that the sooner the wound is healed, the better, and that it is not of service to draw forth much sap at the wound. Now it is certain that a wound never begins to heal till the tree has put forth its leaf. It has no means of making new wood before it has leaves, for the sap that forms the new wood passes through the leaf. From the time of trimming, then, to the forming of the leaf, your wound is exposed to the weather, and the process of healing has not commenced.

We find that when a limb is cut in July, there will be about as much new wood made to cover the wound, during the season, as when the limb is cut earlier. There is a critical time, however, in July, between the first and second growth of the season, when the sap will run from a wound, and will discolor the bark for a foot or more below it; we notice this in trimming nursery trees, and we think trimming in July is not judicious.

As to the comparative waste of sap in March and May, we call the attention of our readers to the practice of tapping the maple for the purpose of gathering sap. All know that no sap can be gathered in May, and not much in April, in our latitude. Sap runs most freely in March. For this reason, we never trim grape vines in March. But after the leaf is formed, the vines will not bleed.

You want a fine saw to trim with, to make as smooth a wound as may be, and if a knife is used after the saw, the wound will heal the sooner. Yet we often see trees trimmed with an axe! We also see the bark torn off of the limbs by the heavy boots of the trimmer. All will own this is barbarous. If you stand on the tree while trimming, you should wear slippers or thin shoes.

When no limbs larger than one inch in diameter are cut, the wound may be expected to heal over in a couple of years; in a thrifty tree it will heal in one year. When only small limbs are cut, there will be no need of covering the wound with clay, or with any kind of plaster. We cannot find that limbs which have been grafted and then covered over with any kind of compost, heal faster than limbs uncovered. A limb should always be cut in such a manner as to let no rain-water stand in the little cup that will be formed by the healing of the wound.

THE DISEASE OF WHEAT—PREVENTIVE MEASURES.

In his excellent report, (says the American Farmer,) as Commissioner of Patents, Mr. Ellsworth alludes to the methods of preventing the disease and attacks to which the wheat crop is exposed. He says that the time when the field is struck with rust, seems to be just at the time of ripening. A remarkable fact on this subject is stated in a report to the New Jersey Agricultural Society. An extraordinary field of wheat, supposed to be out of danger, on a hot day became drenched by a sudden shower, which came on between 1 and 3 o'clock, P. M. All was still; and on the passing away of the shower, the sun came out intensely hot. The owner went into his field to examine his wheat, which he found much pressed down by the shower; he immediately perceived a continued ticking, or snapping noise, in every direction. The straw was fine and bright; but, on examining it, he found it bursting in short slits one quarter of an inch long, and the sap exuding from it.

A day or two after, the whole field was darkened with rust, and the wheat nearly ruined. Another instance of the same kind is also related.. The conclusion stated is—that the loss of the sap, running out and becoming dried on the straw, occasioned the rust. The ancient Greeks and Romans attributed rust to the effect of the weather on the grain, as has been mentioned above, and had a prayer to the supposed Rubigo for warding off the disease.

He says that, to avoid the fly, manuring high at seed-time and sowing late, were resorted to. But that this was attended by mildew and rust. The best means of prevention are—first, a good, dry, loamy soil, well prepared by cultivation, and not too recently manured. Secondly, cover the seed about two inches deep, either with drill or plow, that it may have good hold of the soil, and not be thrown out by winter frost. Alluding to the various expedients to protect wheat from smut, he says:

"One directs the wheat, after being thoroughly washed, to be soaked 10 or 12 hours in salt water, as strong as it can be made. It is further said that no injury will result if it lies in the brine for several days, provided it can be in a cool place. After thus soaking it, let it be limed. Another person recommends that the seeds, when placed in the brine, be stirred up thoroughly, so that the light seeds may rise to the surface, and be skimmed off; afterwards, that the brine be drained into a tub, and the seed thinly spread on the floor, and sifted with quick-lime, at the rate of one gallon to a bushel; and, after carefully stirring the lime through the seed a few times, it is allowed to remain a few hours, and then sown. The seed which underwent the perfect cleaning gave a return of pure wheat—and that which was sown in its natural state was infected with smut, and had a mixture also of chess.

"In a Northumberland report on agriculture, it is stated that Mr. Culley, who grew annually from 400 to 600 acres of wheat, had but one instance of smut in 40 years, and this was when the wheat was not steeped. Another experiment on seed, in which were a few balls of smut—one third being steeped in chamber ley, and limed; one third being steeped in the same, and not limed; and the remainder without steeping or liming; and the result was, that the seed pickeled and limed, and that pickeled and not limed, were free from smut, but the other had smutty ears in abundance. Another experiment was tried, by taking a peck of very smutty wheat, of which one-half was sown in its natural state, the other half washed as clean as possible, in three waters, soaked two hours in brine strong enough to bear an egg, and dashed with lime; the result was, two-thirds of the unwashed was smutty, but of the pickeled and limed seed there was a full crop, without a single ear of smut. A similar experiment, somewhat varied, is the following: Of four sacks of smutty wheat, one was soaked in strong brine only; one prepared with lime only; one was soaked in strong brine, and then lay in lime all night; and the fourth was sown without anything: the result was, where brine only was used, now and then there was a smutty ear, but not many; where lime only was used, there was about the same quantity of smut; where lime and brine were used, not a single smutty ear could be found; and where nothing was used, it was a mass of smut. In another experiment, however, mentioned in the Southern Planter, wheat salted at the rate of a quart of salt to a bushel succeeded effectually in preventing smut.

THE BLACK BIRD.

The black bird is one of the species against which the efforts not only of idle boys, but our farmers, are directed on account of its habit of attacking the Indian corn at the time of its sprouting from the ground. It is somewhat vexatious, to be sure, to have this injury done to our corn crops; but before the farmer engages in the warfare against these birds, he should take into consideration the fact, that they save ten times the amount of corn they destroy. They pick up thousands of insects that would do far greater damage.

There are only two short periods while the black birds remain with us that they eat vegetable food; in the spring, when the corn is sprouting from the ground, and in autumn, when it is matured. The remainder of their summer's sojourn is spent in rendering us the most essential aid. On opening the stomachs of these and others, worms, bugs, small reptiles, sometimes as many as fifty or sixty of these may be discovered in the stomach of each bird.

HOW TO CLEAN A FOWLING PIECE.

Stop up the touch-holes by means of a little wax, and then pour quicksilver into the barrels, and roll it along them for a few minutes. The mercury and the lead will form an amalgam, and leave the gun as clean as the first day it came out of the shop.

Strain the quicksilver through a piece of thin wash-leather, and it is again fit for use, for the lead will be left in the strainer.

"PRIDE OF CHINA."

It is not generally known, says the Hamburg Indagator, that the berries of the "Pride of China," or as it is commonly termed, "*China Tree*," will protect dried fruit from worms, either in the green or ripe state.

When fruit is sufficiently dried for packing away, gather a few of those berries, say one third in quantity to the fruit, and mix them; or scatter a few of the berries on every layer of the fruit. This precaution will keep out worms, and leave no disagreeable taste.

The China tree is of more value to man than he is aware of. The leaves will also protect his cabbages from the ravages of worms—the berries make good soap, are rich manure, and the roots possess medical qualities. The trees are easily reared, and make a delightful shade.

☞For cleansing brass, take 1 oz. oxalic acid to a quart of alcohol. Rub with a woollen rag till dry. It has been tested, and with great satisfaction to many.

ACTION OF LIME ON SOILS.

Mr. Ruffin, in his Report on his Agricultural Survey of South Carolina, comes to the following conclusions with regard to the offices performed by lime on soils:

1. In neutralizing the acid principle of soil which is generally present in all naturally poor soils, and which is poisonous to all cultivated and valuable crops. The total removal of this poisonous quality of soils is an immediate and the most obvious effect of the application of calcareous manures.

2. In the power of altering the texture and absorbency of soils. The admixture of calcareous manures with soils, serves in an important degree to moderate the previous opposite defects of being either too open and light, from excess of clay, and also of being either too little or too much retentive of moisture.

3. By alteration of constitution in soils, produced by calcareous manures, all products are rendered more perfect and are ripened earlier.

4. Some lime being essential to the formation of every plant, it may therefore be considered a specific and *climentary manure* for every crop. Still the *direct* operation is, perhaps, the least benefit of lime. Some plants, however, of which clover is one, require so much of this ingredient, that they can scarcely live on ordinary soils.

5. Another operation of calcareous manures, and which is very important also in agricultural and pecuniary value, as well as for other considerations, is that of restraining or perverting the production of *malaria*, or the gaseous products of putrefaction of vegetable matter, injurious to health. No effect yet claimed for the operation of calcareous manures was at first heard with more incredulity than this; yet the short experience of 12 or 15 years only has been enough to remove almost every doubt on this subject in lower Virginia, where marl has been most extensively applied.

6. By furnishing to any soils which had been previously very deficient therein, an ingredient in calcareous earth, essential to their good and perfect constitution, all the functions of the soils and of plants growing thereon, are made more perfect and invigorated: and every source of injury to the crops, whether from soil, season, depredations of insects, or other diseases to which may be alike exposed the marled and unmarled parts of the same field, will be much less hurtful (if even perceptible in effect) on the former than on the latter. The calcareous manuring does not prevent or even lessen these causes of disease and death, but enables the plants, by their greater vigor, to withstand and out-grow the inflictions, and thus renders them comparatively harmless.

No agricultural writer in our country has paid more, if as much, attention to the properties of lime, its action and benefits, in the melioration of the condition of lands, than Mr. Ruffin, and, therefore, we take the more pleasure in presenting the above conclusions of his mind, after many years of intense study, close observation, and practical experience.

We are gratified to see, that among the properties possessed by lime, he assigns to it that of being an "*alimentary manure*," a property which we have long since claimed for it, but which few were willing to allow it, even amongst those who were warmest in its praise as an improver of soils. We based our opinion of its being a nutricious, as well as mechanical agent, upon the fact that all analysis of vegetable substances, grown upon limed land, have shown very distinct traces of calcareous matter, and hence we drew our deduction from that fact, that if it had not operated as nourishment, the lime thus detected as a constituent of such vegetables, would not have been taken up by their roots and distributed through their entire series of stems, leaves and fruit or berry; for to us it has long appeared obvious enough, that unless the portions of lime taken up contributed to the sustenance of plants, their organs of feeding would have had the instinctive sagacity to reject them; or if not so, that the lime taken up would have exerted a deleterious influence upon their growth and elaboration, as well as upon the maturation of their fruit and seed. But while we have thus thought and contended, we have always maintained, that, however important the agency exerted by lime—however essential its application was to the improvement of soil, that still animal and vegetable manures were indispensable pre-requisites, in any perfect system looking to the effectual restoration of lands which might have been exhausted of their fertility.

By the analysis of plants of various kinds, their constituent properties have been found to consist of many substances; and it is but fair to infer that each and all are necessary to their healthful development.

There is one of the offices exerted by lime which appears to have escaped the notice of Mr. Ruffin. We mean the active agency which it performs, in facilitating the decomposition of inert vegetable bodies, and converting insoluble into soluble substances; thus bringing into active and available use countless organic remains which had laid dormant in the earth for ages, and which but for the decomposing powers of lime would so have continued to remain for ages to come. In this way, lime may be considered not only a *manure* in itself, but the manufacturer of *manure* also. Peat, we know, without something to bring its dormant constituents into a state of fermentation, would continue to be unavailable as an improver of soil, and yet the moment it becomes admixed with a very moderate portion of lime, a new constitution or capacity seems to be infused into it, and from that moment may we discover the commencement of decay—from that moment does the process of decomposition begin—from that moment does its inertia become aroused into activity—and just such an effect as we have described to be produced on peat, does lime exert on all the *inert* bodies to be found in the earth.

There is another effect of lime upon clays that we had intended, when we commenced this article, to have remarked upon, but as our able friend of the *Maine Farmer* has treated the subject—the action of lime upon the potash found in clays—better than we could, we copy his article:

Improvement of Clay Soils by Lime and Burning.

Lime has been used upon soils for centuries, sometimes with good effect, and sometimes with no apparent effect at all. Various theories have been brought forward to explain its action where it did good, and its want of action where no benefit was apparent.

Some parts of the theories, or explanation of its action are undoubtedly correct; but, as every year the research of farmers and chemists bring something new to light, we see that we did not know all about the action of this substance, and, of course, all our theories could not be correct. That lime enters into the composition of some plants, when combined with other substances, and thus becomes "part and parcel" of the crop, is true—that it also renders some stiff clays more open and easy of culture, is true—that it combines with acid matters in the soil, is true. A German chemist, while experimenting on lime and clays, observed that if common potter's clay, or pipe clay, were diffused through water, and this added to milk of lime, (common whitewash,) the mixture would thicken immediately. If this mixture be kept for some months, and then strong acid be added, the clay would become a sort of jelly, (or gelatinous,) which it would not have become if it had not been mixed with the lime. It appears that the lime, on combining with the clay, changes its character, softens it down, or liquifies it, and also liberates the greater part of the alkalies which it contains. Here is a hint towards explaining the action of caustic or quick lime upon stiff clayey soils, which will guide the farmer in its application to the soil. It acts as a key to unlock the imprisoned alkalies, which are indispensable in the production of stem and fruit, and thus become a valuable agent. To effect this on very stiff clay, requires quite a large amount.

Clay is made up of alumine and silex, and sometimes of potash. Alumine, when combined with potash and sulphuric acid, forms, as every one probably knows, the common alum which we buy at the shops. Many clay soils contain all these elements, but very intimately combined, and are then more or less barren; because those elements, or at any rate, the flinty part and the potash, or alkali, are necessary to the growth of the plant. Now, any process which will disunite the materials and render them capable of being taken up by vegetation, will be advantageous to the farmer. One mode is to add lime as above stated. Another mode is to burn the clay.

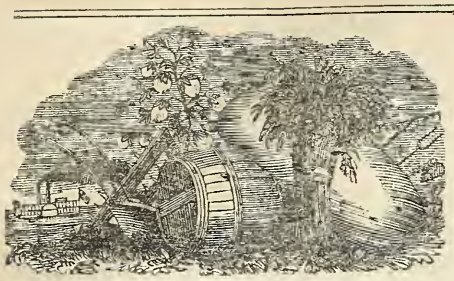
The plan of burning clayey soils has been long known, without any definite idea of the why or the wherefore of the cause of the benefit. It has been found, however, by the chemist, that if you take a lump of clay in its native state and put it into any of the strong acids, it will not be acted upon at all, but if you heat it to redness a short time, and then apply acids, you will find that an essential change has been effected; it will then be acted upon by sulphuric acid—the alkali and albumen combining with it, and the silex or flint being separated in a jelly or gelatinous form. You have often seen newly built brick houses become coated with a white coat, or powder, in moist weather. What is the cause of this? Why, the alkali which was in the clay before the bricks were burnt, becomes, by burning, liberated, and is brought out, or dissolved, by the moisture, and when the moisture evaporates, remains on the wall, like a white powder. On a careful examination of walls that show this powder, it will be seen that it generally appears first where the lime of the mortar and the bricks are in contact. Hence we see that the operation of lime upon clayey soils is more or less beneficial accordingly, as it acts upon the alkaline material in the clay, and also that an improvement is effected in such soils by burning. The latter, however, is an expensive process, and cannot always be used.

From the Manchester Operative.

I HAVE NO TIME TO READ.

The idea of many that they have not time to read is a mere phantom. Did not Franklin find time, in the midst of all his labors, to dive into the hidden recesses of philosophy and to explore an untrodden path of science? Did not the great Frederic, in the midst of a war, yea on the eve of a battle which was to decide the fate of his kingdom, find time to revel in all the charms of philosophy and intellectual pleasures? Did not Buonaparte, with kings in his anti-chamber begging for thrones—with thousands whose destinies were suspended on the brittle thread of his arbitrary nod, have time to converse with books? Cæsar, when he had curbed the spirit of the Roman people, and was thronged with visitors from the remotest kingdom, found time to cultivate his intellect. And every man has time; if he is careful to improve it as well as he might, he can reap a three-fold reward.

Let the mechanics and laborers of the United States then make use of the hours at their disposal, if they want to obtain a proper influence and rank in society. They are the life-blood and the sinew of the community; they can, if they are so disposed, hold in their own hands the destinies of the republic; they are numerous, respectable and powerful; they have only to be educated half as well as other professions to make laws for the nation, and cause the drones and aspiring demagogues to leave their fat offices, which they hold, and pull off their white gloves, and apply their hands to work. Let every laborer, then, devote more of his time to study and the acquisition of useful knowledge. There are but very few who cannot devote daily two hours for mental cultivation. If they would do even this together with combination, how much greater would be their influence and how long would labor be considered as disgraceful?



WEDNESDAY, JULY 24, 1844.

Our Correspondents.—We can but congratulate our readers on the manifestations of an increasing and growing interest on the subject of agricultural improvement which is being developed in Georgia and the South generally, and in nothing is this more strikingly illustrated than in the number and character of our correspondents, which we are much pleased to announce are increasing, and we have assurances from others of their intention to favor us with the results of their observations and experiments. In this connection we must inquire, why has our early and much esteemed friend and correspondent John Farrar, to whom we are indebted for many favors, been so long silent? We hope he will continue to enrich our columns.

"I would suggest the changing the next volume of the Cultivator to the octavo form, as it will make a more convenient form for use. How would once a month do, instead of twice a month? Would it afford more time for communications, &c.? These are mere suggestions; of course, you must consult your own convenience, &c."

The above is an extract from the letter of an esteemed correspondent, to whom we are indebted for several valuable communications that have adorned our columns—and from whom, we are gratified to learn, our readers may expect others. And, as we have had in contemplation the changes he suggests, it may not be improper, on this occasion, to state frankly to our readers and friends our purposes in reference to the future.

We have already been negotiating with a distinguished gentleman of Georgia, well known to the scientific world, who has devoted much attention to the subject of agriculture, and a writer of acknowledged ability, to take charge of the editorial department of the "Southern Cultivator;" and we indulge the hope that we shall consummate the arrangement—in which event, it was our purpose either to change the present form to an octavo of twenty-four pages, or continue it the same size as now, with sixteen pages, and issue it monthly. The acquisition of an editor of acknowledged ability, we feel assured, would be most acceptable to our readers, and we can but indulge the hope that the proposed alterations would be equally acceptable to a great majority of our friends. To accomplish this, however, we must throw ourselves upon the kind offices of our friends, and invoke their aid in extending our circulation in every section. The rate of subscription is so low that we cannot possibly send agents through the country; and, to enable us to engage the services of an editor so competent as the one in contemplation, our friends must bestir themselves to extend our circulation.

The arrangement, however, if completed, will be announced in due time, and prospectuses will be sent to our friends and patrons early in the fall, with such an appeal as we may deem fit and proper on the occasion.

The Crops.—A friend from middle Georgia writes us under date of July 6: Corn crops are fine, plenty of roasting ears in the fields on the 1st July. Cotton large for the season, some bolls appear to be grown or nearly so.

TO DESTROY BED BUGS.

As the hot season approaches, (says the Prairie Farmer,) there will be desperate endeavors on the part of the vermin nations to extend their settlements. Nor will domestic affairs be at all neglected by them. But as their interests generally clash with those of the tenants of buildings, closets, and particularly of beds, a contest for superiority frequently takes place. In these contests it is very desirable to be armed with proper implements, as on that the success of the war mainly depends. Hot water, pepper, tobacco, and smart-weed, are frequently relied on; but we believe that in such cases the victory is very generally, finally, with the biting and odor-bearing party. We advise the use of *mercury*, or quicksilver, as the most effective instrument that can be employed. It is not material in what form it is applied, provided it is strong enough; but we believe the pure article beat into the white of an egg is perhaps as cheap and effective as any.

We have tried this, and have found that the vermin cannot endure it at all. A very small quantity is sufficient to ensure an immediate surrender.

☞Graft Grape Vines when the leaves are putting out, as the sap is then thicker, and the vine will not bleed and drown the scion. So says the Boston Cultivator.

☞Plow up the ground you intend to put in turneps as soon as you possibly can, taking care to divide your manure between the first and last plowing. Be sure to plow deep—subsoil if you can—and make the soil as fine as harrow can make it.

☞Gapes in chickens may be easily cured by giving them small crumbs of dough impregnated with a little soft-soap; once or twice is sufficient.

☞For bots in horses, give one ounce of slaked lime three times a week, mixed with his food, for three weeks.

☞A good book and a good woman are excellent things to those who know how to justly appreciate their value; but there are many who judge of both only by their covering.

From the New England Farmer.

COMPOST MAKING.

The leisure time which the farmer has in summer, cannot be more profitably employed than in gathering materials for, and making compost. Let large drafts be made upon the muck-bed, the surface earth of woodlands, the swamp, bottoms and sides of ponds, and the road-side; gather all useless vegetation, weeds, brakes, &c.; keep the hogs well supplied with the "raw material," and your investments of this kind, in their manufacturing establishment, will bring you in as good a profit as the most sagacious capitalist derives from his investments in other sources of gain.

It has been contended that the employment of men at a dollar per day, during the summer months, in getting materials for compost, would be a profitable expenditure of money by any farmer, and we cannot dispute it.

The more means a man has to do with, in any pursuit, (we mean a wise man,) the greater is his thrift—uncommon contingencies aside—and how emphatically true is this in the case of the farmer. Only give him a plenty of means in the shape of manure, and he can get, ordinarily, as much as he wants from the earth; for, when liberally treated, she yields liberally; but you *can't cheat her*—you can't give her little and expect much.

Ho! then, farmers, for the peat meadow, and dig into its deposites with an animation and a spirit, such as you would be likely to exhibit were you digging in a prolific mine of gold. Let each resolve to outdo his neighbor in the making of compost: get up an enthusiasm in the matter. This, sometimes, accomplishes much: we have seen its effects in politics, in temperance, and other matters; let us now see it excited in compost making. He, among our subscribers, who shall make the most compost this year, with the least means and at the least expense, shall have all the fame which the publication of his achievement in our columns can give—beside the more substantial benefit of increased crops and improved fields. In respect to this business of muck-digging and compost making, we would say—

Let those now dig who never dug before,
And those who've always dug, now dig the more.

From the American Farmer.

PIGS SUCKING A COW.

In an Illinois journal for the present month, I see a notice of a cow, when lying down, deprived of her milk by a porker. It reminds me of a matter occurring under my own observation, which I will mention, and when you see Col. Bomford of the Ordnance Department, mention it to him, as from the short acquaintance I had the gratification to form with him in 1840, when on a visit to his house with my much lamented uncle, the late Hon. Henry Baldwin, I was happy to see, and make improvement of his knowledge of the habits and instincts, sports and pastimes, of domestic animals.

For several weeks in succession, our dairy-maid complained that our best cow was deprived of her milk by some foul means. That when she came from pasture she had just been milked, and that the udder was still wet. I could accuse no one but a tenant who lived near the lane through which they passed, and which was generally open from the cow-yard to the pasture. The accusation was denied with evident surprise. At length I determined to watch the cattle on their evening walk from the pasture, and you may judge my surprise, when I observed that on the cow mooing as if in search of her calf, about fifty yards distant from the yard, four shoats, three months old, ran squealing down to meet her at their utmost speed. The cow remained in the rear of the others, and quietly and patiently stood still till every drop of milk was extracted from her udder by the pigs; they *standing* the while erect on their hind legs, with each a teat in its mouth. The place for the operation was most favorably selected, as small apple-trees interposed between the parties and the house, which stands upon an elevation. The extraordinary thrift of my pigs, which all along was so discernible, was now accounted for; and I learned a lesson which shall never be forgotten through life, viz: never to make accusation on mere circumstantial evidence unless strongly corroborated.

I shut my pigs in a pen immediately. The next morning the cow appeared as uneasy without their visit as if she had lost a calf, and the pigs squealed in answer as if they had been deprived at the time of their mother *sus*.

Now, as Professor Silliman thought his story worth publishing, I have concluded to *write* mine to you.

Preserving a Goose-Egg Under Ground.—I was walking this morning behind my plowman, when his plow turned up from the soil, at the depth of about 8 inches, a goose-egg of very rusty complexion. Almost taking it for granted that it was spoiled, I opened very carefully a small space in one end, with the point of my knife. As no explosion ensued, I made the opening still larger, and to my surprise found the egg perfectly sweet, and its different parts perfect, with the exception that it contained a *very small embryo* completely developed. The white of the egg was as clear and sweet as if newly laid. There was no possible perceptible difference—the yolk was of the natural color and entirely sweet to the smell. The egg must have been in the position from which it was taken, at least twelve months. There can be no mistake in the matter. The ground where it was deposited was a deep, mellow, alluvial loam. Oats had been sowed and harvested last year, and the ground seeded to clover, which, from some cause not having taken well, I am plowing the same land for corn. The egg must have been plowed under last spring. Something, perhaps, may be learned from this; at least of interest to the good lady of the farm-house, if not to others.

Jos. C. G. Kennedy.

Hillside, near Meadville, Pa., 30th April, 1844.

For the Southern Cultivator.

LEGISLATIVE AID IN PROMOTING AGRICULTURE.

Mr. Editor—Some of the States have thought agriculture of sufficient importance to receive legislative encouragement. State premiums are offered for agricultural products, and a corresponding spirit of emulation and improvement is manifested among the farmers of those States. Science, too, is lending her aid to agriculture, and the time will come when the scientific farmer will rank as high in intellectual attainments as the members of other professions. Shall the State of Georgia remain inactive, when other competitors are about to pass her in the race of agricultural distinction? Agricultural labor is of vital importance to every country—the farmer is the main support of human existence. He is the life-blood of the body politic, in peace and in war; the burdens of the country rest upon him, and the brightest pages of history are adorned with his gallant achievements. Freedom, patriotism and virtue, after being driven from the degeneracy and corruption of cities, will find their last resting place in the bosom of the agriculturist. He should then be held in the highest estimation by all other callings and professions.

Will the Legislature of Georgia longer withhold suitable encouragement to agricultural improvements? Let a State Agricultural Society be formed, offering liberal premiums for the best improved farms, stock, implements of husbandry, &c. If, by such means, every acre of arable land in the State should be made, in time, to double its production, the resources of the State would also be doubled. It would, in effect, be the same as adding to the State of Georgia another State of the same size. Will she, then, refuse a small sum annually, in order to effect so great a consummation? It is hoped the next Legislature will evince the wisdom of the reduction of its members by suitable legislation on the subject.

A committee on agriculture, of the Legislature of one of the most improved and scientific farming States in the Union, report that "they believe full one-third of all agricultural labor is literally thrown away by misapplication." Such an estimate is probably not overrated, even as regards our own State. The Legislature, then, should not hesitate to use all the means in her power to restore the lost third part of the labor to the State, by establishing a State Agricultural Society, but should also avail her citizens of the benefit of the improvements which science is adding to agriculture. This can be done at a small expense, by establishing at her University a professorship on the applications of Chemistry and Geology to agriculture. Such a professorship would annually disseminate a large fund of information among the people of the State, upon scientific agriculture, that would be invaluable. It would add more dignity and honor to farming, rank it with the learned professions, and afford useful employment to many young men who now are mere drones upon society.

Liebig, Jr.

☞It is said that ringworms may be, in most cases, simply cured by scratching around the outer surface with the point of a sharp needle. The disease will not pass the line, if the skin is thus cut.

☞To involve yourself in inextricable difficulty, shape your course of action not by fixed principles, but by temporary expedients.

A Turkish Trap.—The Marchioness of Londonderry was inspecting the palace of the Sultan, and had arrived at the extremity of a magnificent room 150 feet long, with a long line of open lattices to the water. "While I was shivering with cold," says she, "and gazing on the Asiatic shore and the delicious view, (which, even in the bleak and dreary month of November, is lovely,) a large square trap-door in the floor was raised, and I heard a voice say, 'Voila la mer, madame!' Hardly believing my senses, I advanced, and truly, the deep, green sea flowed under the splended eastern gallery. A shudder came over me as I thought how readily that trap door might close over its victims, and my blood ran cold while my imagination made the mute inquiry, who can tell on whom that barrier has closed? I recalled the lines,

"When wearied of these fleeting charms and me,
Here yawns the sack, and yonder rolls the sea,"

and I turned away and gladly obeyed the summons to proceed."

Punch on long Dresses.—It is a fact that ladies at present wear very long dresses.—Every fact in female fashions is meant expressly to attract notice; accordingly, we feel called upon to notice this.

Evil has ever its counterpoise of good. It is sad to behold the train bedraggled with mud, but consoling to reflect that it sweeps the crossing. The dust that saturates the flowing robe might else have bedimmed the boot of Wellington.

The drapery which shrouds the exquisite instep conceals, also, the discolored stocking. What matters the bunion, unespied? Elegance may be veiled by superfluity of vesture; but it is in the power of her proprietress to elevate the flounce; nor need the ankle of symmetry absolutely be sandalled in vain.

Heedlessness, going down stairs behind Beauty, may tread on her skirt; but the laceration of the garment is good for trade.

Time is one thing: Extent another. The dress of loveliness may reach from here to Jericho; but what lady, willingly, would wear a gown longer than a week?

Castor Oil.—We have been presented with a specimen of this invaluable medicine, manufactured by Joshua Willis, of Troup county, Ga. It is a most beautiful article, and will bear a favorable comparison, even in appearance, with that brought from abroad. Mr. Willis is manufacturing the article at his farm in Troup county, in large quantities, and is offering it at as low a rate as it can be possibly sold by those who bring it from a distance.—We trust he will meet with the success his undertaking merits.—*Columbus Enq.*

Crops.—A letter from Smithland, Ky. says: "The rains in the West are daily and tremendous. We yesterday had an awful thunder storm, accompanied with one of the hardest rains I almost ever saw fall. It reminded me of the August rain of 1813, in New-York. The wet weather is doing much damage to the growing crops."

American Hemp.—Nearly 5,000 bales, or 1,123,500 lbs. of American Hemp were received at Boston from New-Orleans during the six months ending on the 1st inst.

TURNEP SEED.

A SUPPLY of the following varieties of fresh TURNEP SEED just received, viz:

Yellow Sweedish or Ruta Baga, very fine for stock,

Large Globe Turnep, } Fine
" White Flat do. } for
" Hanover or White Ruta Baga do } table
" Norfolk do. } use.

For sale in quantities to suit purchasers, by

Aug. 30 18-tf WM. HAINES, Jr.

GARDEN AND FIELD SEED.

A GENERAL assortment of fresh and genuine GARDEN and FIELD SEED, among which are the following:

Red and White Clover,
Blue and Green Grass,
Rye and Orchard do.,
Timothy and Herds do.,
Millet and Lucerne do.,
Seed Corn of every valuable variety,
Seed Wheat,
Buckwheat and Potato Oats,

Kept constantly on hand by the subscriber, all of which are offered for sale at very moderate prices. All orders, by mail or otherwise, executed with neatness and despatch.

EMIGRATION.

The principal motives to our citizens of the planting States to emigrate to the West, were, formerly, the restless disposition of the people of a new country—the greedy avarice of the acquisition of land—and the strong propensity (to some extent commendable) to accumulate wealth. I speak not of those who were driven from their homes by crime, or made wanderers by the union of pride and poverty, or those who sought professional employment; but of planters. Many of them were also weary of cultivating lands which, under their rude agriculture, gave early signs of exhaustion; and, being ignorant of the modes of renovating soils, and indeed, (had they known them,) probably deficient in the steady energy and philosophic patience requisite to apply them successfully, they preferred rather to encounter the difficulties of settling a wilderness, for its advantages of rich land, its facilities for living, and its freedom from restraint. And no doubt they all attached full credit to the exaggerated accounts of the wonderful fertility, and incomparable climate of that region, which yielded in perfection all the products of the earth; of its immense forests, filled with game, and its rivers with fish; of its extensive prairies, rich and perennial meadows for stock: that it was exempt from the fatal diseases of old countries, and that they would immediately possess a princely domain, and in a few years, a princely fortune.

Led captive by an excited imagination, and disregarding the plainest precepts of wisdom, they sacrificed, some of them, ease, competence and health—abandoned friends and relatives, their old homestead, tolerable lands and reasonable prospects, here, for an *ignis fatuus* of wealth in distant parts. Experience, however, soon taught them, and with indelible impression, all the privations and sufferings to be endured, the manifold obstacles to be subdued, and the almost superhuman labor to be achieved, in order to secure even moderate success. The deception which had carried them far away, to drag out in sickness and its consequent poverty, a miserable life, was exposed and denounced over and again by many, who cherished the hopeless resolution to come back again when able. A few returned, broken in fortune and in spirit, yet happy to pass the rest of their days amid the scenes and the society of their birthplace. Others who had gone early, and with large capital, selected the best locations—and, by indomitable energy and judicious management, received a fair compensation. But none have realized their vain imaginings, or have discovered yet a Hesperian garden.

The spirit of adventure was essentially checked by these discouragements. People were no longer seen moving in crowds and by companies, but singly, or by families, and at intervals: some prompted by a vague desire of change, or the genius of enterprise, the great moral feature of our countrymen; and others from a disposition to invest their surplus means in wild, but fertile lands, and await a future day for interest upon it, when the increase of population would create a demand for them. These were legitimate causes of emigration, and had no tendency to depopulate any section of the old States. But the recent praises of Texas soil and climate—the prospect to both political parties of the South, of its early union with this confederacy, and the fear that citizens of the West and Northwest, by immediate removal, may secure all the favorable situations in that country, are calculated to awaken anew the feeling of speculation. The signs that are exhibited around us, cannot be mistaken.

To those who have already determined to leave us, and are yet inclined to think before they act, I will offer a few considerations, which may be worthy of their deliberate attention. And first, it is by no means certain that Texas will be annexed. The period for adopting this measure may have passed forever. Some of her late papers intimate that if her independence is acknowledged by Mexico, she can maintain a national existence, and will refuse to unite with us. And it is said that France and England will use sure means to obtain this recognition, if she will abandon the idea of annexation. But if, on the contrary, she again consents, it is said that the North, while willing to abide by the terms of the Constitution and not interfere with us, will never sanction the admission of a foreign slave State. The South will, of course, only receive her as such. Can there be a compromise between these conflicting parties—the adherents of the institution—who believe that it has bestowed upon them countless blessings, and are opposed to taking any step for its extinction, or to modify it at all; and the people of the North, who are strongly and naturally averse to it, from the want of necessity for its use among them—from the public opinion of the world—and (with a large portion certainly) from jealousy of the happy division of classes it has adjusted at the South; and of the aristocratic ease, and consequent genius, manners, high-toned honor and undaunted courage, it has imparted to those educated under its influence? It is to be hoped there will be, (I express no opinion, and venture no conjecture,) yet it will be seen that difficulties attend the speedy termination of the controversy; and those who, under the fairest auspices, might be persuaded to emigrate there, should, on this ground, pause for the present. But the fever to leave, being once thoroughly enkindled, no disappointment with regard to Texas can allay it. The resolution formed to go, and preparation made for it, home and its occupation are no longer attractive, and they will move, at all events, to Mississippi or Louisiana.

What I am about to say, may, therefore, be as fully applied to these States as to Texas. Notwithstanding the high authority of General Thompson to the contrary, all that country must be more or less unhealthy. It is an axiom that rich lands are sickly: they are fertile mainly by the vast accumulation of vegetable matter, and under the action of moisture, and the intense heat of that clime, which continues the greater part of the year, fermentation and decay are constantly going on, and the most deadly miasmata are evaporated. Seatsfield, who, by the way, is a close and shrewd observer, who seems to have caught, instinctively, the spirit of every scene and of every character he has portrayed, and is peculiarly interesting to us for his genuine Southern feeling, remarks somewhere, in reference to Louisiana, (and Texas is essentially the same,) that the country might do, were "the heat and vapors less oppressive; the atmosphere less hot-house like; and the moschetoes less ravenous,—but these draw from you the last remnant of warm and pure blood, and leave little more than red cool salt-water in the veins, creating salt humors, and cruel liver complaints." His description of the cypress swamp, and its sociable inhabitants, and seas of muck, and lying adjacent to the settlements, too, is enough, it would seem, to content a sensible man with a *pine barren*, where good water, robust health, and long life, would be the accompaniments of a moderate income. He says further, that the black earth in some places is 18 feet in depth, and the mud slime, on the banks of Red River, is 16 feet deep: a mass of muck that Dr. Dana would, no doubt, behold with rapture. Can health reside here? I would as soon look for it in the Pontine Marshes of Italy, or in the diked mud-flats of Holland, where, I believe, the average of human life is about 20 years. There are some situations, it is true, which are better than others, but the pestilential vapors of such extensive swamps and bottoms as are found there, must contaminate, more or less, the whole atmosphere. And the annual ravages of the yellow fever in some parts, the bilious fever in others, and the liver complaint and pleurisy in all, are satisfactory proofs of the fact. It may be said, that desire in the pursuit of riches is never counteracted by fear, and rumors of sickness and death excite no alarm in the enterprising, who risk everything for the certainty of gain—(this may be an abstract truth, but I leave the dissussion and disposal of it to each one's feelings)—that since large fortunes can be rapidly made, as asserted, a short residence only will be necessary, when the product of their enchantment may be wafted to a purer clime, and the enjoyment of it be enhanced by the hazard of procuring it. And indeed, to come more directly to the practical objects of this paper, that a larger amount of cotton, and of better quality, can be grown to the acre, the soil richer and more durable, the climate more genial, and the living more abundant and cheaper.

The fertility of the land, and the benificence of the clime, are undeniable. The fatal diseases which they generate, have been mentioned. The cost, to an emigrant, of an improved river plantation, will average 25 or $30 an acre, some being as high as $50. This requires a large capital to begin with. The greater number who move, would thus expend their all for a place. The failure of the first crop would involve him in serious embarrassment, and especially if he has obtained his land on credit, which is by no means unusual. He must part with some of his negroes to meet the necessary payments. A second failure would ruin him irretrievably. The recent overwhelming flood, which, it is estimated, has destroyed nearly half a million of bags of cotton, and corn in proportion, is a specimen of the chances of failure. These chances will increase, in proportion to the clearings along all the branches to the main river, until, in a few years, they will become regular annual visitants. The cream of the

land, the mud slime, (of Seatsfield,) all of alluvial character, (susceptible of culture,) will be again taken by the current which originally deposited it—and the planter who boasted of his wealth in it, must yield it to the flood, and flee for his life. This evil has done its worst with us already. Our rivers and creeks are cleared to their sources, and lands which have not latterly been regularly submerged, may be considered safe forever, and their high value fixed. The price of land, not immediately on the high-ways to market, is from 10 to $15 an acre, depending on quality and situation. To prepare it for planting, requires almost, to us, inconceivable labor. The forests are dense, and the growth colossal; and it has been asserted that $10 to the acre, will not more than cover the cost of clearing. Thus time and arduous work, are necessary for preparation, and expenses are accumulating. A failure in the crop here, would be ruinous likewise; and though beyond the reach of high water, perhaps, yet no section there is exempt from the desolating effects of the rust, the worm, lice and caterpillar, which exact an annual tribute from the crop, and sometimes share the whole of it among themselves. Besides the steady rains of several week's duration, which often destroy, and always stain a large proportion of it. And here, as on the river, sickness might prostrate the entire force, and a fine crop be left in the fields to rot. The mortality, too, is very great, and the profits of the most successful plantations are largely drawn upon to supply the deficiency among the hands, which the fever yearly creates. There is little breeding among them, and of course no increase, save by accessions from the more Eastern States. But a still sadder fate may overtake the emigrant. He might procure, in his own judgment, and in that of his lawyer, an indisputable title to his land, and yet be sued for it within a year, and his claim be extinguished by the verdict of a jury. Such mishaps have occurred to the most acute: and I have recently been informed of an instance of an accomplished lawyer, who emigrated, paid $10,000 for his place, prepared to plant, was sued by some claimant of his land, and turned off it by due course of law; yet, he knew the difficulties and risks of land claims, and gave a thorough inspection to his title before paying the money. This was within the United States. What must be the uncertainties in Texas, where land has been granted by the league, and scrip for it sold and re-sold, with sometimes forty claimants for the same tract. This will more than counterbalance the difference of the price of land in Texas and Mississippi; and yet the best plantations there are dear, and should it be annexed to us, they would, no doubt, advance several hundred per cent.

The climate is more fruitful: a longer period is permitted the plant to grow and mature. Yet an enlightened planter has asserted, that, taking the vicissitudes of the seasons into account, the 33rd parallel of latitude is the most favorable for the growth of cotton. Although the plant is indigenous to a lower latitude, and the seed grown here cannot be used continuously, year after year, in consequence of the rot—which experience proved, some years ago, to have arisen from predisposition of the seed, and which was entirely remedied by procuring more Southern seed; yet soils yield all plants in greater perfection by occasionally changing the seed, as well as changing the crop, and at any rate, planters would have made this exchange. It is very little trouble or expense to procure, every year, a few bushels of seed from Texas or Louisiana: and, as the quality of this last was imparted to it by admixture of the Sea Island with it, (vide Seabrook,) we have only to plant the black seed with our own, in order to obtain an equally good staple.

With regard to the cheapness of living, they are all as dependant, for mules and meat, upon Tennessee and Kentucky, as the worst managers among us are, and pay about the same price for them. But we have made a commencement to supply ourselves, at least, with meat, which is a great point gained. A few planters, scattered here and there, are unable to raise stock. It becomes the prey of runaways and theives, and is destroyed. The community must engage in it and distribute the losses. We have made fair progress: much the larger part of our planters buy no meat, and in a few years, it is to be hoped, that neither horses, nor mules, nor hogs, will be supplied us, from beyond the mountains. The beginning has to be made in the Southwest, and it may be asserted with truth, that our subsistence is *cheaper* than theirs.

Turn, now, to the picture which home presents. Our lands are entirely our own, and are amply furnished with stock and implements, and with all requisite buildings and machinery. Still, the best of them are valued at from 5 to $10 an acre, and the average may be had at from 2 to $6. True, they are scarcely comparable to those of the West, which produce 2,000 and 2,500 lbs. seed cotton to the acre, (and not 4,000 lbs., as Gen. Thompson said in his Texas letter,) though rarely is the half of it gathered—while ours yield ordinarily an average of from 500 to 800 lbs. Yet, they are far easier worked, and more of it can, therefore, be tended; and, if we will apply in time, rest, and labor, and manure, a moiety of what it would cost to break up and move, to buy and settle other lands, and prepare them properly for planting, (without adding the high cost of mortality in our force,) we can, *on the first rotation*, make them yield a *bag to the acre*, and do it afterwards *in perpetuo*. Suppose a planter with 3,000 acres of average land: He sells for $15,000, and emigrates to Louisiana: He buys a choice place there of 2,000 acres, which he deems enough, and pays $60,000 for it; or, if he gets it at $25 the acre, $50,000; or, if he prefers to be off from the river, he pays from 20 to $30,000. It has cost him from 500 to $1,000 to move, including, if you please, the loss of part of his crop, which he must leave in order to reach his new place in time to prepare for planting, provided this last is improved; and at least ten times that amount, if he has it to clear, in time, and work, and subsistence, without adding what he could have made and saved in the meantime, on his old plantation. He can gather only about five bags to the hand after all, taking one season with another, and probably he would not average it; for, should it escape all the evils which I have alluded to, his force could not pick out much more than this, and do justice to his plantation improvements. What if we were to expend the half of one of these sums, even of the smallest, in making and spreading manure, and adopted the system of rotating, resting, and cultivating to advantage, would we not make more than we could possibly gather? would not our worn old fields bloom like an enriched garden spot? Could we not make an abundance on ½d the land we now till, and work our negroes lightly, employ our surplus force in mending stock, (of which we would soon have a superabundance,) procuring timber and lumber for market, and making all requisite improvements? No plan can be devised to render us more prosperous and independent, and it is this which, sooner or later, unavoidable necessity will compel us to adopt.

We are freer from the insect, and from disease, than in the West, and are never flooded by high water; nor is the crop injured, or diminished, by the incessant rains of a more tropical clime, nor torn up by the awful tornadoes which sometimes desolate a whole region, and which Seatsfield depicts with great accuracy, and power, and effect. We have an earlier market, being on the Atlantic, and can realize half a cent more for our cotton, than if in equal competition, which will pay the difference they obtain in the quality of theirs. We are comparatively healthy, with air which is not saturated and heavy almost to cutting, as theirs is, with the miasm of the swamps; and water, which they cannot dig from their mud banks, nor filter from their lime prairies. We enjoy more of the luxuries and pleasures of life, and are, therefore, higher in the scale of rational existence; for civilization consists in the multiplicity and vanity of our wants, physical, moral and intellectual. We mingle in a more refined society and educate our children in higher principles, and for nobler objects, than the gross scenes of Western life exhibit—where wild sports and vulgar pastimes supersede moral development, and physical energy predominates, to the exclusion of intellectual culture. And indeed, the mass of our advantages over them, far surpass that of theirs over us; and, with skilful management and well-directed industry, we are competent to equal them in their boasted privileges.

But my article is long enough. The subject is full of interest, and at this crisis of importance, and susceptible of a variety of views, which, at a future time, I may present. I have said enough to awaken attention; and if it deters a single family from risking the loss of all they possess, and peace, comfort and health, to venture among the disastrous uncertainties of Western life, my effort will be amply repaid.

A Burke Planter.

For the Southern Cultivator.

CULTIVATION OF COTTON.

The Improvement in the Cultivation of Cotton in the Flat Woods—The susceptibility of the Improvements of the Lands shown by Experiments.

Mr. Editor—It is known to a great many people in this section of country, that the flat-woods of Elbert county was once thought to be unfavorable to the culture of cotton, though late experiments have shown the suspicion to be incorrect; however, in its original state, it is not altogether so well adapted to the production of cotton as higher lands, especially with careless farmers. David Bell, a practical farmer of this county, has proven, from actual experiments, that cotton may be grown, to an advantage, on any land in the Southern clime, where the temperature, and the length of the seasons, will admit of its being raised at all. He has shown the good effects of manures—enough so to induce any farmer to turn his attention to the subject. He is now making a small experiment upon one acre of land, which has been cleared and abandoned years ago, and thought to be irreclaimable—which is supposed to be the case with most of the lands in the flat-woods, when "wornout:" this is also proven to be incorrect. This acre which he has manured, is now in a state of high cultivation—and it is thought it would not be extravagant to say, that it will make 2,000 lbs. of cotton, from its present appearance. His manner of manuring is simple: he finds that litter from the woods, with little of the soil, of itself is an excellent manure; and when combined with the litter from stock, or cow-penned upon, answers, in a high degree, the reclaiming of most any land—and adapts it to the culture of most of our productions. He finds that low lands, when properly managed, can be made to produce cotton finely. From what observations and experiments he has made, the result of his conviction is, that there is more advantage to be derived from properly planting a crop, than unthinking farmers have heretofore been aware of. He invariably well prepares, and throws his lands, where he intends for cotton, as high as a turning plow will admit of; and where his land is any way low, he uses the hoe to bring it to a proper elevation.

Land done in this way, produces cotton to as early maturity as desirable. He finds it to farmers' interest, to cultivate a small quantity of land to the hand; which, by a proper system of manuring, will yield more to the farmer, than double the amount otherwise cultivated. And, though he is in favor of "annexation," yet he

thinks in this way the territory can be increased to a considerable extent, without extending it one inch. There is one kind of annexation, he thinks, perfectly practicable—that of applying manures in abundance to their exhausted lands; which will advance the farmer's interest, and afford the best protection that could be desired. Try it, farmers, and the happy effects will be the result. A. A. B.

SELECTIONS, EXTRACTS, &c.

From the Columbia South Carolinian.

OVERSEERS—No. II.

We often hear planters boasting of having made six, eight, and sometimes ten bags of cotton to the hand, and when one speaks of making a "fine crop," it is understood that he has turned out five or six bags or more per hand. Occasionally an old planter will take the liberty of inquiring of one of these fine croppers how much corn he has made, but seldom venture further. Now it is this very erroneous idea, that a large number of cotton bags constitute of itself a "fine crop," that is so fatal to all improvement in planting, and so ruinous to overseers. What does it avail a planter to make ten bags of cotton to the hand, if he has to buy corn and meat—if his mules break down—his negroes decrease, and his lands go to nothing?

My idea of a "fine crop" is, first, an increase of negroes; second, enough made on the plantation, of meat, corn, &c., to feed every thing abundantly; third, an improvement, rather than a deterioration, in the productive quality of the lands; fourth, the mules, horses, farming utensils and fences all in first rate order by Christmas; and then, as much cotton as can be made and gathered, under these circumstances. And I will venture to assert, that no planter will thrive, in the long run, who does not make fine crops of this sort. Nor will agriculture steadily improve, until all planters are of this opinion, and act upon it; and not only planters, but overseers. In the vocabulary of overseers, "a fine crop" refers wholly to a fine cotton crop. They boast of nothing else at the muster-ground, and road-working, where they carry, with perhaps a commendable vanity, the first form, first bloom, and first grown boll. When they seek a place, they rest their claims entirely on the number of bags they have heretofore made to the hand, and generally the employer unfortunately recognizes the justice of such claims.

No wonder, then, that the overseer desires to have entire control of the plantation. No wonder he opposes all experiments, or, if they are persisted in, neglects them; presses everything at the end of the lash; pays no attention to the sick, except to keep them in the field as long as possible, and drives them out again at the first moment, and forces sucklers and breeders to the utmost. He has no other interest than to make a big cotton crop. And if this does not please you and induce you to increase his wages, he knows men it will please, and secure him a situation with.

Until planters, therefore, generally come to the opinion, that it is necessary to attend to other things besides making cotton, to get rich by agriculture, it will be impossible to reform overseers, or increase either the individual or aggregate wealth of the country. And that this conclusion is a just one, I appeal to the experience of all planters. During the recent hard times, has any single planter been brought to the block, unless for security debts, who made all, or nearly all his articles of consumption within himself, though he made ever so small crops of cotton? On the other hand, how many of the ten-bag planters have been swept away? In fact, does it not somehow happen, that almost all such planters are, sooner or later, in a very ticklish condition? And generally, they leave to children reared on the ten-bag scale, wornout lands, and broken down negroes. Cotton is *the* great crop, but not the only crop. Energy is a great thing in planting, and doubtless the fundamental principle of success, but something else is also requisite—judgment, care and foresight.

But I am writing about overseers. I wish to see them reformed. Planters must, I fear, first reform themselves. But if they could only be induced, when overseers apply to them for places, to ask the following questions, in the following order, and engage or not engage according to their answers, I believe it would, if the plan was universally adopted and kept up for five years, do more to improve our agriculture than five hundred cattle shows, as serviceable as I think them to be.

1. Will you obey orders, implicitly, promptly, and fully?
2. How many negroes were under your charge last year?
3. How many births had you?
4. How many deaths?
5. How many hogs did you raise?
6. How much corn did you make?
7. How much manure?
8. What experiments did you try?
9. How many of your mules died?
10. Did you leave every thing in good repair?
11. What was your crop of cotton?
12. What is your price?

FRANKLIN.

From the American Agriculturist.

AGRICULTURAL ERRORS.

So many glaring scientific errors find their way into our agricultural works, that I am afraid, unless rectified at home, they will make us the laughing-stock of Europeans. If these works had only a limited local circulation, such errors might be amusing, yet would scarcely be deserving of notice; but as many copies of our works on agriculture find their way to other countries, and are there perused by scientific readers, we must either criticise them among ourselves, or we shall be considered totally ignorant of the science we so glibly write about. I am sorry to undertake so disagreeable a task, and can assure the writers of the articles I am about to review, that I am totally unacquainted with either of them, and that my only object is to save the credit of our common country.

The first article I shall notice, is one written by Mr. Noyes Darling, of four columns, inserted in the Albany Cultivator for March, on lime as a destroyer of sorrel. Mr. Darling is correct in supposing that oxalic acid is formed from the elements of the plants in which it is found; but in error when he gives hydrogen as one of the elements of oxalic acid, this acid being composed of only two elements, carbon and oxygen. It is still more strange that Mr. Dana should prescribe lime as a cure for the growth of sorrel, when it exists in this place as an oxalate of lime, and could not grow in any soil unless lime was present.

The juice of sorrel changed, by a process well known by the operative chemist, to oxalate of potash, has been much used in the arts, and sells at a high price. I have sold it at $3 per pound, and it is now selling at $1. There are about four species of plants which contain oxalate of lime; four species that contain binoxalate of potash, and only one known species (the *cicer parietinum*) that contains uncombined oxalic acid. If this cicer could be cultivated in any part of our country, it would afford a valuable acquisition to the useful arts, in supplying us with oxalic acid, which is now imported at a cost of nearly 50 cents per pound.

A few drachms of oxalic acid will operate as a violent poison; but a small quantity with sugar and water forms a pleasant cooling beverage, and is considered a fine antiseptic. I have drank many gallons of oxalade, and punch made sour with oxalic acid.

I had written thus far, when a friend handed me a work called the Muck Manual, by Mr. Dana, requesting me to review it. I had not read many pages before a suspicion flashed on my mind, that this work had been perused and taken for authority by Mr. Pell, and hence several errors in his article on "Charcoal and its Uses," in the April number of the Agriculturist. This shows the importance of professional writers being correct, and no excuse can be made for Messrs. Dana and Darling. They are my superiors in literature, and the scientific errors they have fallen into, particularly Mr. Dana, who I am informed is an analytical chemist, must arise from a want of due investigation.

I believe Mr. Dana is considered a good analyser of mordants and coloring-matter, and is of course a valuable citizen in such pursuits; yet it struck me with no little surprise, that a practical chemist should have adopted so wild and unsupported a theory. Chemistry is altogether a practical science, and the first lesson I learned, forty years ago, was never to give credence to any theory that was not supported by direct and well-ascertained experiments. This axiom was established by the chemical savants of France in the early period of the science, and when departed from, the chemical world will produce theories as wild and unstable as were those of the old alchemists.

There appears to be a natural tendency in the human mind to sketch imaginary pictures, instead of troubling itself in tracing realities. If we enter a steamboat or hotel, it is much if we do not see some head hung up, phrenologically mapped; we cannot look at a paper, but we observe advertisements of a lecturer who talks about some epileptic, or cat-aleptic ladies, to prove mesmeric phenomena; and what is worse, a large audience looks on and sucks in all as established truths. Several attempts have lately been made by chemists, of more or less celebrity, to run into unsupported theories, which require to be kept in check by the more sober portion of its followers.

Boullay, an European chemist, observed some few years since, a black or dark-brown substance which exuded from the bark of the elm, to which he gave the name of ulmin. It is very sparingly soluble in water, but readily soluble in solutions of the alkaline carbonates. He found its constituents to be carbon, hydrogen, and oxygen, and termed it ulmic acid. He considered it identical with the brown matter of vegetable mould, and as contributing materially to the nutriment of growing plants. Several chemists of the day pursued the subject, and made rather a plausible theory from Boullay's discovery. It will surprise no one that Liebig should take it up, and pursue it with his usual transcendental energy; for even the acute and accurate Berzelius gave it credence for a time, but soon acknowledged his error.

There is no mistake in supposing that carbon, hydrogen and oxygen, contribute very materially to the nutriment of growing plants, for we know that the greater portion of all plants are composed of said elements. Nor is there any difficulty in supposing the exuded substance contained an acid, as almost all the known acids found in the vegetable world are binary, or tertiary compounds of those three elements.

So far as I have read Mr. Dana's Muck Manual, he has founded the chemical portion of his work entirely on the now exploded theory growing out of Boullay's discovery.

I shall renew this subject in a future essay, and review Mr. Dana's work more in detail.

WM. PARTRIDGE.

From the Albany Cultivator.

"KNOWLEDGE IS POWER."

Never was this motto more signally illustrated than in the advantages derived by intelligent farmers from the aid of science. Even a slight acquaintance with chemistry and geology, is productive of profit to the pocket, as well as pleasure to the mind.

"You may be somewhat surprised to find me farming on the hard soil of Connecticut, instead of teaching mathematics in a ship of war," said a worthy friend to me lately; "I am somewhat surprised at the transition myself," he continued; "but the truth is, that upon leaving the ship on a visit homeward, I bought a copy of Liebig's newly published book about Agricultural Chemistry, for the purpose of reading on my journey; and so much was I instructed and en-

tertained, that I determined to take hold of the old farm once more, and endeavor to practice on the doctrines taught by that scientific German. I have done so for a couple of years, and the result more than realizes my expectations. By economy in increasing the quantity and improving the quality of manures, and by applying more manure and better cultivation, our corn crop is more than doubled—aye, trebled; our potato crop is much improved in quality, and greatly in quantity; and our meadows produce hay enough to leave a handsome surplus, where formerly the cattle we now keep would have found rather 'short commons.' But the greatest improvement in reference to the cattle and meadows, results from adopting the plan which I saw mentioned in the Cultivator, as pursued by Hon. Josiah Quincy, of Massachusetts. The old stone fences running through our farm, were a nuisance in my sight, forming ready harbors for noxious vermin and weeds, besides occupying considerable ground. I determined to follow the Quincy fashion, (and those Quincies have many good traits about them,) by soiling our cattle, and thus rendering division fences needless. I thus keep the cattle in better order on the products of much less land, and save additional quantities of manure that would alone pay me for all the trouble I have in housing the animals. By under-draining, I have reclaimed considerable marshy land, making it now productive; and the peat-bog of twelve acres, formerly a mere nuisance, is now one of the most valuable parts of our farm—furnishing us with abundant material to throw into our hog-pen and cow-yard, for forming compost, in connection with an occasional sprinkling of lime to promote decomposition. I should not forget that even the weeds with which the old farm was infested, are now made tributary to the improved mode of cultivation; for, cut frequently, (as all weeds should be,) till they are exterminated,) they form material for additional manure, when drawn into the hog-pen or cow-house for litter. It is satisfactory to find that many in our neighborhood, who at first smiled incredulously at my notions of *book-farming*, (and also some well-meaning doubters, who are always slow of faith,) are now satisfied there is something in it less ridiculous than they formerly supposed. So, with this brief account of myself, since you last met me on board the line-of-battle ship, do you wonder that I have now returned with increased interest to the old farm, where I learnt to plow in the same fields that were cultivated by my ancestors, from the early settlement of Connecticut?"

As one of the multiplying evidences of the beneficial results of agricultural publications—as an example worthy of imitation by many of our farmers, young and old—the foregoing sketch is at your service—in the hope that young men who are inclined to abandon farming in the hope of better fortune otherwise, will at least "*read, reflect and judge,*" before they abandon their farms, however "worn out" or unprofitable those farms may have been. Farmers who practice on such doctrines, have little need of crossing the Rocky Mountains in search of lands in Oregon. Rho.

From the Boston Mercantile Journal.

FATTENING TURKEYS.

On looking over some old papers a few days ago, we came across the following curious mode of fattening turkeys:

"In the winter of 1818-19, a gentleman in this city made the following experiment:—He placed a turkey in an enclosure about four feet long, two feet wide, and three or four feet high. He excluded as much light as he could without preventing a circulation of air, and fed the turkey with soft bricks broken into pieces, with charcoal also broken, and with six grains of corn per day. Fresh water was daily supplied. The box or coop in which the turkey was placed he always locked up with his own hands, and is perfectly confident that nobody interfered with the experiment.

"At the end of one month, he invited a number of his neighbors, among others, two physicians. The turkey, now very large and heavy, was killed and opened by the physicians, and was found to be filled up with fat. The gizzard and entrails were dissected, and nothing was found but a residuum of charcoal and bricks. To conclude the examination satisfactorily, the turkey was eaten, and found to be very good. Last winter he again repeated the experiment with the same success.

"The circumstance which induced him to make the experiment is a very curious one. One of his neighbors informed him, that being driven from the city by the fever of 1793, his family recollected that some fowls that had lived in a kind of loft over his workshop, had been forgotten in the hurry of their removal, and would certainly be starved. They were absent six or eight weeks, and on the retiring of the pestilence returned. To their great astonishment, the fowls were not only alive, but very fat, although there was *nothing* but *charcoal and shavings* that they could have eaten, and some water that had been left in the trough of a grindstone had supplied them with drink."

It appears from the above that turkeys are a species of biped that thrive best on a Graham diet.

AGRICULTURE IN COMMON SCHOOLS.

The following is the report of the committee on Agriculture, as adopted unanimously by the New York State Convention of school superintendents recently held in the city of Rochester.

Report on Agriculture.—The committee, to whom was referred the consideration of the subject of introducing the study of *agriculture* as a branch of education in our schools, respectfully report—

That, as *agriculture* is the art on which all other arts depend, and the profession in which the greater part of our population are engaged, its improvement and prosperity is a subject of the highest importance; and the committee are of the opinion that the time has arrived when the elements and scientific principles of agriculture should be taught in all our schools, especially to the older class of pupils.

The rapid progress which has of late years been made in those parts where the discoveries of science have been brought to bear on the improvement of agriculture, affords the strongest evidence of the importance of diffusing a knowledge of the principles upon which these improvements are based, among those who are soon to become the owners and cultivators of our naturally fertile, though much abused soil. There can be no doubt but that such knowledge, if properly imparted, would have a direct tendency to improve the practice of agriculture, and elevate the profession to that high rank in public estimation which it so justly deserves.

Your committee have perceived, however, that there are numerous difficulties connected with the subject, and that it requires more deliberate consideration than they have bestowed upon it, to devise the best means for accomplishing the object. Much can be done by the introduction of books on agriculture into the district school libraries. This object has received considerable attention from the New York State Agricultural Society, and premiums are now offered for the best essays for the purpose. There is still wanting a suitable *text book* on agriculture, for the use of schools.

In view of this whole subject, therefore, the committee beg leave to recommend this subject to the earnest consideration of this convention, and to submit the following resolutions:

Resolved, That this convention recommend to teachers, as far as is in their power, to impart instruction on agriculture, by occasional dialogues or conversations, and the reading of agricultural books and periodicals, so as to explain the principles of this art, and show its respectability and importance to themselves and society.

Resolved, That the convention deem it of the highest importance that our school libraries contain more works on the principles and practice of agriculture, suitable for the perusal of the young; and therefore we take pleasure in recommending to the trustees of school districts under our charge to purchase works of this character.

Resolved, That we will, as county superintendents, take the subject into consideration, and be prepared, at our next annual convention, to express our opinions respecting it, and to act decisively upon it, if deemed advisable.

Resolved, That a committee of three be now appointed to take this matter under their special consideration, and report thereon at our next annual convention; and that the State Agricultural Society be requested also to appoint a committee to confer with them.

A committee was appointed, consisting of Dr. Alonzo Potter, of Schenectada, Ira Patchen, of Livonia, Liv. co., and M. B. Bateham, Rochester.

From the Boston Cultivator.

CHANGE OF CROPS.

Messrs. Editors—In Ruffin's Survey of S. Carolina it is said, while advocating a change of crops, "Corn seems to need change of soil less than any of the great crops, and the many cases of success with which it has been raised for many years in succession on the same fertile field, have been triumphantly advocated by the opposers of rotation, as a certain and manifest proof, that a change of crop is not necessary; but even if this were true, as to this particular plant, it would not affect the general question. The hardiness and vigor of the corn plant on fine soil, may enable it to withstand the depredations of some of the several tribes of insects which it breeds and nourishes, and others, as the cut-worm, so fatal in other circumstances, may be destroyed by the continued tillage, and naked and open state of the soil."

Now, where the soil is fine, and every way suitable to the growth of the plant, other crops beside corn, are sown several years in succession with impunity. At Mr. Mark Cooper's farm, near the village of Enterprise, Lancaster Co., Pa., a second crop of wheat in succession is at present the finest in that wheat-growing country; and I was informed by the owner, it was his intention to follow it with another crop of the same! and on my remarking, I never before witnessed such liberties taken with the soil, he informed me of a crop of rye then growing in the neighborhood, the 27th in succession, not having received a spade-full of dung for 27 years! On visiting this field, I found a good crop, clear from rust and heavy in grain, and not a weed in ten acres! and when asked by the owner why he might not continue his *rotation*, as he jeeringly termed it, I confess I felt somewhat dum-founded, and could only answer, I considered the present an exception to the general rule. I plucked a sample of the crop, and present it to you as a specimen of the 27th crop of rye in succession, without any manure.

To the remark, that "cut-worms in corn may be *destroyed* by continued tillage and a naked and open soil," I beg to say, the cut-worm would not be found in corn, were it not planted in sward or sod land: they are the progeny of a species of beetle or other insects, which could never propagate its kind without the aid of dung, which is found in grass fields that have been fed by horses or cattle, and in this they enclose their egg or eggs, and sink them a given distance below the surface; hence, an autumnal or winter plowing of such land destroys them, by exposure to the rains and frosts of that inclement season; a doctrine which has at last met with the concurrence of every practical man amongst us. And a change in the common rotation, corn, oats, wheat, clover, for wheat, corn, oats, clover, will be quite effectual in putting a stop to its ravages. The observation, that corn or any other grain "breeds and nourishes insects," I must say is quite in opposition to my views on the subject. I believe that insects are destined to prey on the vitiated juices of the plant, which, instead of circulat-

ing, become stagnant and ooze through their pores; and it is on these putrid and extravasated juices, that the animals feed. Now we always see, even in the most blighting seasons, that some plants—those for instance that might be sheltered from a cold and blighting atmosphere—will be found to have escaped the general evil, while others are doubly afflicted by the malady; but if asked how these things can be accounted for, or by what peculiar means they were brought about? I can only answer, reverently, God knows!

NEW MODE OF FARMING.

I pray you, Messrs. Editors, permit me to detail, what appears to me, a new mode of farming. It was communicated in the way of conversation with an honest old German, who informed me he had purchased a small farm of 70 acres in the neighborhood of the Lehigh coal region, where also he had charge of a lock on the canal; that the next year he should have a *taller* (larger) farm, and devote himself to its cultivation. I inquired if he would grow corn? 'Yes.' And wheat? 'Yes.' Oats? 'Yes, for the fodder, and cut it all up together, grain and straw.' Would he keep a dairy? 'No, only one cow for my wife, as I do not care for milk and butter.' Hogs? 'No, only one or two to eat up the waste about the house.' Then what stock would you keep? 'None in summer, but plenty in winter.' I then desired him to detail his plan, which he did in his quaint manner, as follows:

"I keeps no cow, no ox, no sheep, no hog all summer, nor plow much. All my land, so much as I can, I give to grass. Then, when my neighbors say, oh, my cows and my hogs get in my corn, and eat all up; I say I keeps no cow and no hog—I very comfortable about my fences; they cost me nothing, for I have no cattle to break them. But I makes the hay so much as I can, and my cornstalks so big as I can, and my oats so much as I can, and save all up for winter; a great barn and stable quite full, and the ricks in the yard. Then I watch my neighbors; for when I hear John Stone say, in the spring, oh, I got much grass, I must buy two cows, when he hant 'nough for one cow, I say to myself, oh, I buy your cows in winter, when you got no hay for them. So when he come and say, you buy my two cows 'cause you got plenty hay; I say yes, I give you five dollar a piece for them; and so I gets them, 'cause he got no hay nor nothing to give them. So I do with the rest of my neighbors, only I do not buy the bad cows, only the good cows what will have calfs; and they keep the bad cows 'cause nobody will buy them. So I keeps them well, and cleans them very nice, and makes them very fat and big; and when the little calfs comes, I gives them all the milk, and they grow fat and big; and then my neighbors comes in the spring, and wants to buy their cows again, for they got the grass and no cows to eat it; and so I sells them their own cows for 20 dollars apiece, and sometimes thirty or forty; but I keeps the calfs, 'cause I wants them for the butcher. And so I sells my neighbors their own cows again, *but I gets all the dung;* and as they gets no dung, they get no crops; while I gets all the dung, and the crops, and the profit too!"

Messrs. Editors, when I hear my neighbors inquire what course they shall adopt, so as not to follow exactly in the path which others are pursuing, I think of my old German friend who "gets the dung, the crops, and the profits too," and am led to ask, if there be any objection to the plan here pointed out.

RECIPES.

An excellent plan for preventing young fruit trees from becoming hide-bound and mossy, and for promoting their health and growth, is to take a bucket of soft soap, and apply it with a brush to the stem or trunk, from top to bottom; this cleanses the bark and destroys the worms or the eggs of insects; and the soap becoming dissolved by rains, descends to the roots, and causes the tree to grow vigorously.

It is said that a mixture of one ounce of saltpetre, and seven ounces of salt, applied on the surface of the ground, in contact and around the trunk of a peach tree seven years old and upwards, will destroy the worm, prevent the *yellows*, and add much to the product and quality of the fruit. Also, dress the orchard with the same mixture, at the rate of two bushels to the acre.

To have green peas in winter, take them when they are plenty, shell them, wash and scald in hot water, then drain, put them into bottles, and pour strong brine on them until they are perfectly covered; over this pour a thin layer of good salad oil, and cork tight, then dip the corks into melted pitch. The bottles should be quite full and kept upright.—*U. S. Practical Receipt Book.*

rom the Boston Cultivator.

COLLARS vs. YOKES.

MESSRS. EDITORS—How much has been said, but how little has been done on the subject of substituting the collar for the yoke in working oxen. That the collar can be made to supercede the yoke for all purposes, there is no question, and that it has been done to manifest advantage, there is no doubt. But there is just one thing more needed: it is for some one to fit up a handsome pair of Devons with a set of elegant harness; their collars fitting the hollow of the shoulder, so as to allow the free motion of the leg; their blind bridles like those for the horse, except not being furnished with bits for the mouth; with eye-flaps decorated with brass plates, bearing the name of the philanthropic owner, by which he would claim and retain the honor of being the first to introduce the humane custom into the country—a distinction enviable from the fact of being the first to advocate the cause of one of the most noble of our domestic animals.

But he who would do this, must have the means of carrying out the experiment; humane, with the determination to withstand opposition and prejudice; desirous to relieve the woes of a race of animals that have been bowed down to the earth and oppressed with the cruel yoke of bondage all their lives long; and then, if endowed with patience in the good work, I will guaranty him perfect success, and an inward satisfaction above all price.

And now, do you ask where such a person can be found? I answer, in Mr. Cheever Newall, of Dorchester, whose elegant place and fine animals designate him as he to whom we might look for the introduction of one of the most useful and important innovations of the age. Oxen, when harnessed in this way, are worked like horses; if single in a cart, the pad of the shaft harness rests on the back; if double in a wagon, two pairs of light shafts are used; while in plowing with the collar, they are equal in speed to the horse, and will be found to go through their labor with as little fatigue; their heads being free and more erect, they will not be liable to drop and die in hot weather.

In Mr. Colman's forthcoming notes of his agricultural tour in England, we shall no doubt find ample testimony in favor of the humane substitution here advocated; for he will daily witness many *teams* of oxen—no longer *yokes*—in the streets of London, taking over the pavements the heaviest loads, with the most perfect ease and facility; their feet shod, and their convenient harness enabling them to pass along the crowded streets without the least difficulty, or danger to the passengers, sure-footed and staunch in their draught, to a proverb. He will also have the opportunity of contrasting this mode of gearing with that now in use on some parts of the continent, where the wretched animals are made to draw by means of chains hung to a broad board affixed to their foreheads by straps passing around their horns!

Your subscriber, J. D.

Salem, Mass.

PROPER DEPTH OF SEED.

Various experiments have been tried to determine the proper depth at which seed should be put. The following is the result of an experiment with maize or Indian corn:

That which was planted at the depth of—

No. 1.	1	inch, came up in	8½	days.
2.	1½	" "	9½	"
3.	2	" "	10	"
4.	2½	" "	11½	"
5.	3	" "	12	"
6.	3½	" "	13	"
7.	4	" "	13½	"
8.	4½	" "	—	
9.	5	" "	—	
10.	4½	" "	17½	"
11.	6	" "	—	

The Nos. 8, 9 and 11, were dug up after 22 days, and it was found that No. 8 had an inch more to grow to reach the surface of the earth. Nos. 9 and 11 had just sprouted, and were short, and three inches below the surface. No. 10 came up in 17½ days, but the tender leaf remained only six days green, and then withered. There is no experiment which shows more clearly the advantage of a shallow planting in a soil not too loose and trodden down than this. The more shallow the seed was covered with the earth, the more rapidly the sprout made its appearance, and the stronger afterwards the stalk. The deeper the seed lay, the longer it remained before it came to the surface. Four inches was too deep for the maize, and must, therefore, be for yet smaller grain kernels.

Petri gives an experiment made on rye, with the following results. The first column shows the depth at which the seed was put; the second, the number of days that elapsed before it appeared above ground; the third, the number of plants that came up:

Depth.	Appeared.	Number of plants.
½ inch	11 days	⅞
1 "	12 "	all
2 inches	18 "	⅞
3 "	20 "	¾
4 "	21 "	½
5 "	22 "	⅜
6 "	23 "	⅛

The root stock forms itself next below the surface of the ground, and if we place the grain deep, it must first put its sprouts to the surface, and form its side branches in a nearer connection with the air. We never find that the sucker roots are ranged from below to above, but the contrary.

From the experiments of Ugazy, who tried 76, with different grains, it is clear that shallow sowing, if the seed is only so far covered as to sprout, and the germ is protected from immediate contact with the air, is preferable to laying the seed deep, because it springs up quicker, and acquires a stronger growth, and has hardier plants.—*Burger's Economy of Farming.*

From the Hamburg Indagator.

BUCKWHEAT.

Why is it that our planters do not cultivate buckwheat more extensively? We are obliged to send on to the North every year for a supply of this article, when it is so easily cultivated at the South. Who that has enjoyed a plate filled with buckwheat cakes of a cold winter's day, but did not wish that it were cultivated more in inithiis a ty. The grain not only makes a delicious nd healthy food for man, but it is useful for stock, poultry, and for bees.

Agriculturists tell us that this grain is cultivated on rough and hilly districts, and on light soils, and yields well on poor soils. That it will produce a good green crop to turn in for manure on their land when little else will grow. It flourishes best on a dry, mellow, loose, sandy soil. In the middle States, it is sowed in July, and is generally cut immediately after the frosts in October. One bushel of the grain is sufficient to sow an acre of land, though if the ground be rich, a less quantity will be sufficient, as it will branch out. For a grass crop nearly twice as much is sown. It may be sown for a green crop after a crop of rye, grass, early peas, or other crops.

ON FEEDING MILK COWS.

The following is an extract from a lecture recently delivered at Alnwick, England, by Professor Johnson, of Durham University, at the desire of the Duke of Northumberland, "on the feeding of stock."

"I have spoken of the various conditions of animals. I will now direct your attention to the milk of the cow. When an animal comes into the world, the parent gives it milk. The parent, then, must nourish its own body, and produce the milk besides. The cow gives a large quantity of milk as soon as the calf is born. And cows that give a large quantity of milk are in general characterized by striking peculiarities. Such an animal, an inexperienced eye would say, is poor and meagre and worth nothing; but when he is told to look at the large udder, and the conformation of the whole animal, fitted for the copious production of milk, he soon learns to change his opinion.

Now, what does milk contain? Curd, or casein, butter, sugar, and saline matter, as you will see on referring to the table. Therefore, if you would feed a cow with food that contains these ingredients in a large proportion, you must give her beans and peas, or you must give her some leguminous crop. Observe, the butter is derived from the fatty matter of the food; and some pastures, as you know, are calculated to fatten. These same pastures would give a milk rich in cream, or that would produce much butter, while others would increase the yield of casein, or would be adapted for the production of cheese. It is clear, therefore, that the constituents of the food must exist in the pasture. Now, you all know that milk is extensively used as food, and is raised for sale, either directly, as by the cow-keepers in our large towns, or in the form of butter and cheese, as in our dairy districts, or it is manufactured into veal. The object of the cow-feeder of the town, is different from that of the true dairy farmer.

His object is to produce a large quantity of milk; and he accomplishes that by feeding the animal upon succulent substances, and such as contain a large quantity of water. In some places, you know, they are said to have little scruple in adding water to it afterward. But they can avoid the odium of this by giving it in the food. Milk, of average quality, contains about 87 per cent. of water; but it is possible to increase the proportion to several per cent. more. Then there are the cheese districts, such as those of Cheshire and Ayrshire, and a different kind of food is made use of in these places from what is employed where milk only is required. If you wish the product of cheese to be plentiful, you must feed the cattle on clover, beans and peas, and other plants that contain a large quantity of casein. A rich milk may be obtained by feeding your cows upon clover, but you may obtain a very rich milk also by putting them early on beans or pease meal. But, if butter be the principal object desired, you must feed your cows upon food containing a large quantity of oil. Indian corn, as I said before, contains a great proportion of oil, and no doubt increases the proportion of cream. Some kinds of fodder also contain more fatty matter than others.

From this fatty matter the butter, as I have said, appears to be derived, and I think by using a little care, a milk rich in butter might be obtained by the use of oil-cake, without imparting any disagreeable taste to the milk itself, or to the cream obtained from it. Then in other places they are in the habit of manufacturing the milk into veal. The young calf it is necessary to feed on such substances as contribute at once to the growth of the bones, and to the laying on of fat. These substances exist in milk, and it may be necessary, at certain seasons of its growth, to give the milk skimmed, at others unusually rich in cream. Thus, in the neighborhood of large towns, where veal is much used, it is usual, when the animal arrives at an age when it ought to lap on fat rapidly, to give it the milk richer in cream, as well as a larger quantity of it. This is altogether a different process from feeding farm stock.

From the Albany Cultivator.

HINTS TO YOUNG MEN.

"Who aims at excellence will be above mediocrity; who aims at mediocrity will fall short of it."—[ANON.

Be industrious. We do not mean here the industry of the hands alone, but that perseverance in whatever we undertake, that is the sure precursor of ultimate success. Never allow the mind or the body to stagnate; activity is necessary to the health of both. Always have some worthy end in view, in whatever you undertake; remembering that to fail with good intentions, is more honorable than success in an evil cause.

Cultivate your mind. It is of more importance to the young, that their reading should be select, rather than extensive. One volume well understood, on any important topic, is better than half a dozen merely skimmed. There are many subjects of general utility, with which every man should have a partial knowledge at least; but it is one of the great faults of modern education to spend too much time on studies that rather burden and clog the mind, than strengthen and inform it for life's practical duties. Reading, or studying without some definite aim, is likely to lead to few useful results. How many men there are who have spent a large part of their lives over books, of whom it may be said, "they remember a mass of things, but nothing distinctly." It is possible to cram the mind with masses of indigestible materials, destructive alike to a healthy and a vigorous action of the intellectual powers. Such is not the cultivation of the mind required by a young farmer.

Be economical. No matter if your parents are worth millions, it is not the less proper that you should understand the value of money, and the honest, honorable means of acquiring it. What multitudes of young men, particularly in our cities, make fatal shipwreck of reputation, health, and eventually of property, by a neglect of this simple maxim. They are aware that their fathers obtained their wealth by habits of industry, but they are ashamed of the very name. They forget that wealth in this country passes rapidly from one to another, and that he who is rich to-day may be poor to-morrow; or that he who relies on wealth amassed by his father, may end his days in a poor-house. It is for the young here to say, whether by industry and economy he will secure competence and respectability, or by extravagance and idleness become a worthless beggar and sponging outcast.

Be just. In the course of life a man frequently finds his interests or his opinions crossed and thwarted by those from whom he had a right to expect better things, and the young are apt to feel such matters very sensibly. But be not rash in your condemnation. Look at their conduct carefully, and be just to the motives that prompt it. You may find, that were you placed in their position, the course you now condemn would be the one proper for you, and the one you would be under obligation to pursue. A little cool consideration would avoid much censoriousness.

Shun avarice. One of the most disagreeable characters on earth, is that of the grasping, avaricious, penurious man. Generosity is perfectly compatible with economy; and the means which enable some of our most noble-hearted, generous men, to do much to benefit and bless mankind, are obtained, not by close-fisted penuriousness, but by economy. The distance is not greater between the zenith and the nadir, than between the covetous and the economical man: the first banishes every just and honorable feeling from the heart, the other fosters and ministers to them all.

Determine to be useful. No matter what may be your condition in life, you have an influence, and that influence should always be exerted in a proper way. The young have no right to fold up their arms, bury their talent, and become the drones of the social hive. Aim high, but with prudence; act with determination and perseverance; let no obstacle drive you from the path of honor and duty, and you may be sure of eventual success. Riches are not within the reach of all: competence is; and the latter condition is preferable in every respect to the first. Remember the Deity helps those who help themselves, and that utility is the great end of human exertion.

From the Connecticut Farmer's Gazette.

DON'T KILL THE BIRDS.

Don't kill the birds—the little birds,
That sing about your door,
Soon as the joyous Spring has come,
And chilling storms are over.
The little birds—how sweet they sing!
O, let them joyous live;
And never seek to take the life
Which you can never give.

Don't kill the birds—the little birds,
That play among the trees;
'Twould make the earth a cheerless place,
Should we dispense with these.
The little birds, how fond they play!
Do not disturb their sport,
But let them warble forth their songs,
Till winter cuts them short.

Don't kill the birds—the happy birds
That bless the field and grove;
So innocent to look upon,
They claim our warmest love.
The happy birds—the tuneful birds,
How pleasant 'tis to see;
No spot can be a cheerless place,
Where'er their presence be.

From the American Agriculturist.

THE PHYSICIAN AN AGRICULTURIST.

Who can be a better farmer than the country doctor? With usually sufficient leisure on his hands to spend the necessary time in the cultivation or superintendence of his acres, more or less, and by profession, as he should be, a tolerable naturalist, chemist, and an observer of the physical laws, with the important advantages of daily observation of their husbandry, and continued and friendly intercourse among the farmers and gardeners of his neighborhood for many miles around him, no one has a better opportunity to excel as a farmer than himself. What but absolute want of taste, and a total absence of all observation and interest in the prolific bounties of nature, should prevent our country physicians from being our best husbandmen and stock-breeders? Of all the professions connected with rural life, commend me to that of the country doctor. I speak it with all possible respect and approbation, and for one I most humbly thank Dr. Stevens for bringing this subject before the public; and I wish now, some one would follow up the hint by a lecture on THE CLERGYMAN AN AGRICULTURIST. After this should come the SQUIRE. What a glorious trio. I cannot help apostrophizing them in the language of the poet:

Parson, doctor, and the squire!
Best adviser,
Best prescriber,
Best decider,
Why not *best* of farmers then?

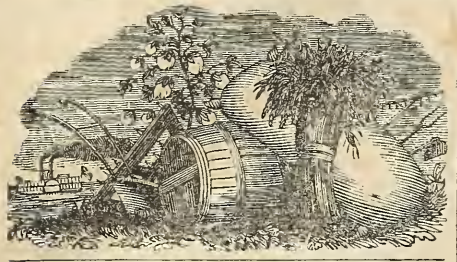
PUTNAM.

From the Albany Cultivator.

TO PRESERVE TOMATOES.

Dip the ripe tomatoes in scalding water, peel them, and divide them into two, or, if very thick, into three slices; lay them on plates, and put them into the oven after the bread is drawn; in 48 hours they will be perfectly dried. Put them in paper bags, and keep in a dry place. When wanted for use, dip them in cold water and lay them on a dish to swell, and in a mince or stew, they are almost equal to the fresh fruit. If you wish to make tomato sauce, add a little water to cook them in. They are very good to eat out of the hand in the dry state.

☞To preserve your horse dung, mix it with vegetable mould, and cover it well with the same.



WEDNESDAY, AUGUST 7, 1844.

☞We welcome with much pleasure the annexed letter from our correspondent, and firm and steadfast friend JOHN FARRAR, and we avail ourself of this occasion to return him our thanks for his numerous and continued manifestations of friendship, since we entered upon the experiment of publishing an agricultural paper in Georgia. He was among the first to take us by the hand and bid us persevere, and he has never faltered in his efforts to secure our success.

There are also many others, who have on all occasions manifested an unflaging interest in our behalf, to all of whom we shall ever feel grateful.

—

STANFORDSVILLE, Putnam county, August 31st, 1841.

Messrs. Editors:—In the last number of the Southern Cultivator, you congratulate your readers on the subject of the increasing number and character of your correspondents, which affords me a great deal of satisfaction to find is a fact. This is as it should be. Is not Georgia as able as any other State to sustain an agricultural paper? I, for one, will say she is. If our planters, as yet, are not able to give an account of as many experiments as to the management of manures, &c., as the Northern farmers are, by applying themselves to the subject, they may, in a few years, be able to do so.

At this time, however, they are fully able to sustain you, Messrs. Editors, in your worthy undertaking, in being the first to hazard the publication of an agricultural paper in this State. It does me good to receive your paper; and still more so, when I can find communications in its columns, written by Georgians; which leads me to understand that there is an increasing interest getting up for the prosperity of your paper. I am at a loss to understand why any planter should value one dollar higher than the advantages of reading an agricultural paper for one year; even if he did not intend to be governed by any of the new plans laid down in farming, there is always enough other matter to be found in such a paper that is well worth a dollar.

In the same number of your paper, you speak of me in rather flattering terms, as an early friend and correspondent, and inquire why I have been so long silent? My friendship, &c., as a correspondent—humble and feeble as my efforts were, in my own estimation---were put in requisition solely for the advancement of your paper; knowing, as I did, that any undertaking of the kind was more in need of help while in its infancy than after it had grown in strength; and if my efforts have been of any advantage to your enterprize, I can but feel glad that I have thrown in my mite. I hope the number of your correspondents will continue to increase, and that they will give the county and post-office from which they write, as I like to know where the different writers live.

As to my silence as a correspondent, I can say to you, that it has not been from a diminished zeal for the prosperity of your paper, nor from a lack of desire to see agricultural improvements progressing, but rather for the want of a subject that I thought would be interesting to your readers; though I think it likely you will hear from me occasionally, before the year is out. I have had a thought of making a request of your subscribers in different parts of the State, to give an account of the crops in their different counties. Such a statement would no doubt afford some satisfaction to the readers of your paper. I will therefore speak of the crops in this section, as correctly as my knowledge admits of.

Corn and Cotton are both better than an average crop thus far. The corn is safe, as we are half done pulling fodder. Cotton, as well as corn, is more forward than common. The wheat and oats crops are both short—though the quality of the wheat is tolerably good.

I am, dear sirs, yours respectfully, &c.

JOHN FARRAR.

AGRICULTURAL EXPERIMENT.

Mr. J. B. LAWES says it would contribute much to advance our knowledge of the action of artificial manures, if the experiments were continued upon the same piece of land during successive years. The problem would then be solved whether a plant can supply itself, year after year, with organic matter, when inorganic matter only is supplied. I found that the ashes from 5 cwt. of dung, produced an equal weight of turnips as 5 cwt. of dung unburnt; but whether the succeeding crops will be as good, remains to be proved. The expense of carriage prevents the use of dung which accumulates in large towns, except by those farmers who live within a few miles; but if the ashes proved equally beneficial, the weight would be reduced nine-tenths, and the expense of carriage almost completely removed.

GUANO.—The price of this celebrated fertilizer of the soil is quoted in the market report of the N. Y. Tribune, at 3½ cents per pound. A cargo of 400 tons was recently landed at Baltimore.

☞Capt. Eldridge of the schooner Emeline, says the N. Y. Farmer, has arrived at Stonington with a cargo of African guano. It can be had in New York at about $50 per ton.

☞Asa Barton, in the Maine Farmer, says that he converted straw, cornstalks, and potato tops, into good manure in fourteen days, only by heaping them together, and mixing unslaked lime with them. He used six casks of lime, and had fifty loads of good manure. The loads measured a large half cord each.

☞We see it stated that a family were recently poisoned by eating rhubarb leaves as greens. The stalks are harmless, but the leaves are said to contain oxalic acid.

A USEFUL PLANT.—The sun-flower is perhaps destined to become one of our most valuable agricultural products. One hundred pounds of the seed afford forty pounds of oil. The refuse of the seeds after expression, furnishes an excellent food for cattle; from the leaves of the plant cigars are manufactured of singular pectoral qualities; the stalk affords a superior alkali, and the comb of the seeds is a choice dainty for swine. So says the Hon. Mr. Ellsworth.

HOME.—Keep your store of smiles and your kindest feelings for home: give to the world only those which are to spare.

☞The tropical fruit, the Prune, has been successfully propagated in Tuscaloosa, Alabama.

☞Nature works for the agriculturist while he is sleeping.

From the Albany Cultivator.

KNOWLEDGE FOR A FARMER.

A comparison of the several kinds of vegetable food, generally used for the purpose of nutrition, cannot but be useful, as showing the farmer what quantity of one, may be substituted for another. The following table, given in Burger, from Petris's work on the "care and keeping of sheep," may be considered as a list of equivalents. It will show that while of some an animal could scarcely eat enough to support life, of others the nutriment would greatly exceed what the wants of the animal demanded.

100 lbs. sweet, well cured meadow hay, containing 50 lbs. of nutritious matter, are equal to		
90 lbs. clover hay,	100 lbs. of which contain	55½ lbs. nutritive mat.
90 lbs. tender vetch hay,	do	55½ lbs. do
90 lbs. tender lentil hay,	do	55½ lbs. do

To keep in equally good condition, it appears from various experiments, says C. W. Johnson, that a horse will consume as much food, besides grain,

As	8 sheep,
A cow as much as	12 "
A fattening ox as much as	10 "
A 3 year old heifer as much as	8 "
A 2 " "	6 "
A 1 " "	4 "
A calf as much as	2 "

GUANO.

The British papers represent the guano business to be about the best going. A vessel of 500 tons was ten weeks on its passage to Africa, seven in loading, and nine in returning to Liverpool. The guano itself cost nothing. The proceeds of the cargo were £4,000, or $20,000; the expenses, $2,000. A British man-of-war has been ordered to the coast of Africa, for the protection of this trade.—*Boston Post.*

The scientific and enterprising agriculturists of Europe, are availing themselves of every artificial expedient to make their land productive. They accumulate the refuse and offal of the world for this noble purpose. Several years ago, we remember to have read that the bones of the thousands slain at Waterloo, which were consuming by exposure to the open air, were collected and shipped to Great Britain, there to be ground into powder and used as manure. Liquid manure, the drainings from stables and cow-pens, is the most valuable of all manures; yet there is not one farmer in twenty, in this country, who saves it.—*Far. Monthly Visitor.*

MOSCHETOES.—Parley's Magazine says, to get rid of moschetoes, take a few hot coals on a shovel or chafing dish, and burn upon them some brown sugar in your parlors and bed rooms, and you effectually banish or destroy every one for the night.

From the Hamburg Indagator.

THE SUNFLOWER.

The people at the South are certainly the most neglectful beings of any other in the Union. Many species of vegetation which grow spontaneous, and without care, possess rare and useful qualities, yet they are passed over as mere weeds, without persons even taking the trouble to ask of their properties. This is the case, however, where Nature has profusely scattered her blessings—we take that which pleases us most, and let the balance go for their worth. For instance, the sunflower which grows on rich and common soils, without cultivation, is of great importance to man. The seeds make excellent food for poultry, and will give a good yield of oil; and after the oil has been expressed from the seed, valuable cakes may be made from the residue, which may be used for various purposes; and acts as an excellent manure for vegetables.

The Palma Christie is another valuable growth, though greatly neglected by Southerners. Our best castor oil is made from its berries. The manufacturing of this article is about to take place in this part of the Union, as we understand from good authority, that a gentleman in Georgia has already tested the experiment, and the product warrants a renewal of the experiment.

From the Western Farmer and Gardener.

PEACH TREES.

See to them. At this season, the worm at the root is very busy, and many trees which you suppose in fine health and vigor, will begin to curl their leaves and grow yellow. Put not your trust in ashes, coals, or tansies. A friend of ours was living in the pleasing delusion that tansy was saving his, and was disagreeably surprised when the writer, removing the ground for an inch in depth, showed him the gum and dust. Follow the worm with a knife, and kill him. You will often find three or four in a young tree; presently your trees have the yellows and die, and you become satisfied that the soil and climate do not agree with them. The yellows very often comes from the worm—some say, always. After taking out the worms, the stem, for a foot above and two or three inches below the ground, may be wrapped with cotton batting, or plastered with a mortar made of lime, sand and ashes.

A GOOD REASON.—A few days since a grand jury out South ignored a bill against a huge negro for stealing chickens, and before discharging him from custody, the Judge bade him stand a reprimand. He concluded as follows:

"You may go now, John, (shaking his finger at him,) let me warn you never to appear here again."

John, with delight beaming from his big white eyes, and with a broad grin, displaying a row of beautiful ivory, replied:

"I wouldn't bin dis time, Judge, only de constable fotch me!"

GROWING MUSTARD FOR FEED AND ENRICHING SOILS.

I beg to hand you the following statement on the use of growing mustard for feed, or to plow in as a preparation for a wheat crop. It is very palatable to all kinds of cattle, and I believe very wholesome. I think it far preferable to buckwheat, or any other vegetable with such rapid growth. I sowed five acres on the 11th of July last, on rather inferior land, of a light gravelly soil with chalk subsoil, where early turneps for wheat had failed. It should be drilled 5 inches apart, with 12 pounds of seed per acre. On the 25th of August, I had measured portions cut in different parts of the field, and weighed, which, on a fair calculation, yielded 6 tons per acre—it was in full bloom—and the next day I plowed it in; which I consider, being full of vegetable matter, must be an excellent dressing for a wheat crop. I would invite any friend to make trial of mustard on better land than mine; the expense being so trifling, compared with buckwheat, which is 5s. per bushel, and requiring 2¼ bushels per acre, would be 12s. 6d., whereas 11 lbs. of mustard seed, at 2d. per lb., the price it is now selling at, would be 2s. per acre.—*Eng. pop.*

From the Farmer's Cabinet.

CUTTING GRAIN EARLY.

We are satisfied that grain is very often left too long standing uncut in the field. The risk of injury from storms is increased—it does not handle so well, either in cutting, binding, loading, or stacking—and shatters out more. The opinion is pretty well established, that when wheat or rye is cut early—we mean before the grain is entirely hard, it makes quite as much, and whiter flour, than if left till the usual time. Since writing the above, we happened to read it to an experienced miller, who is also a good farmer. He says that he is well satisfied that early cut grain—that which is apparently quite green—will really yield more flour, and is worth several cents a bushel more than that which is suffered to stand till the berry is thoroughly hardened.

LIABILITY OF A HUSBAND.—*Lane vs. Ironmonger.*—This was an action, tried in the Court of Exchequer on Monday, at the instance of a milliner in Aldersgate-street against a corresponding clerk in the house of Rothschild for £52 10s. 6d. for millinery supplied to his wife from May to December last.

The delivery of the goods, and the reasonableness of the charges were distinctly proved, but it was contended on behalf of the defendant, that he was only liable for necessaries for his wife, and family, and not for any other debts which her extravagant whims induced his wife to incur, without his knowledge and consent. In support of the defence, there was evidence that the defendant and his family lived in a small house at Hornsley, kept two female servants, and that his income as clerk at Rothchild's did not exceed £300 per annum. It appeared however, that Mrs. Ironmonger had an income of about £400 a year settled on her for her separate use. The bill for which the action was brought contained charges for ten new bonnets, and nine cleaned and altered, and also a charge of forty-three pairs new kid-gloves. It also appeared, from the evidence of Mrs Robbins, a milliner and dressmaker in the neighborhood of St. Martin's lane, that she had supplied the defendant's wife with goods between May and November 1843, to the amount of £50, which had since been paid by the defendant. The defendant now paid £15 into Court, and denied his liabilities for any greater sum.

The Chief Baron told the Jury that a husband was only liable for goods furnished to his wife, when his authority was given expressly, or was to be implied. Perhaps a jury would be warranted in implying that a wife, living with her husband, was authorized by him to order necessary clothing for herself and children. It was for the jury to say, however, if nineteen bonnets and forty-three pair of gloves, within a period of seven months, could be considered necessary for the wife of a clerk with £300 per annum.

The jury, without a minute's hesitation, returned a verdict for the defendant.—*English Paper.*

BACON'S LARD LAMPS.—A new article, superior to all others for this purpose, emitting a good clear light without smell or smoke, and at an expense, counting Lard at 8 cents a pound, of about a quarter of a cent an hour.

These Lamps have been satisfactorily tested, and are recommended as "just the thing" for the use of planters. and all others who study utility, neatness and economy.

A supply of the above Lamps, with Fillers and Wicks for them. For sale by

HAVILAND, RISLEY & CO.

jy 24-d,c&Cultf

TURNEP SEED.

A SUPPLY of the following varieties of fresh TURNEP SEED just received, viz:

Yellow Sweedish or Ruta Baga, very fine for stock,

Large Globe Turnep, } Fine
" White Flat do. } for
" Hanover or White Ruta Baga do } table
" Norfolk do. } use.

For sale in quantities to suit purchasers, by

Aug. 30 18-tf WM. HAINES, JR.

GARDEN AND FIELD SEED.

A GENERAL assortment of fresh and genuine GARDEN and FIELD SEED, among which are the following:

Red and White Clover,
Blue and Green Grass,
Rye and Orchard do.,
Timothy and Herds do.,
Millet and Lucerne do.,
Seed Corn of every valuable variety,
Seed Wheat,
Buckwheat and Potato Oats,

Kept constantly on hand by the subscriber, all of which are offered for sale at very moderate prices. All orders, by mail or otherwise, executed with neatness and despatch.

EXTRACT FROM RUFFIN'S SURVEY.

Cause of the Rust in Cotton—Corn, Rotation of—Ravages of the Insect—The Pea Crop: its advantages as a rest or manure crop under a burning sun—The Sweet Potato—Grasses—Clover, etc.

The *rust* of the growing cotton is one of the most general and most destructive diseases to which that crop is subject. Sundry causes are alleged for this disease, some or all of which may truly be auxiliary or even inducing causes to the main one, which (according to my general position before stated) I take to be the depredations of myriads of very minute insects, to which the green cotton plant furnishes their best, if not their peculiar food. Other circumstances, of weather or soil, at different times, may serve to increase or check, or even prevent the depredations of these insects; but the circumstances which increase their injurious effects, could not operate, unless the insects were present. And it may be presumed that they would not be present, or be very few in number, if the preceding crop had not been cotton, but some other crop on which these insects could not live. In confirmation, I understand that cotton is rarely attacked by rust, when it does not immediately succeed cotton. The other diseases of this crop may be ascribed to other tribes of insects; and the means of prevention, either partial or effectual, would be also a change of the continued succession of cotton, and the intervention of a condition of the soil as unlike as possible to that under cotton culture.

Corn seems to need change of soil less than any other of the great crops; and the many cases of success with which it has been raised for many years in succession on the same fertile field, have been triumphantly adduced by the opposers of rotation, as a certain and manifest proof that a change of crop is not necessary. Even if this were true, as to this particular plant, it would not affect the general question. The hardiness and vigor of the corn plant on a fine soil may enable it to withstand the depredations of some of the several tribes of insects which it breeds and nourishes; and others (as the cut-worm, so fatal in other circumstances,) may be destroyed by the continued tillage and naked and open state of the soil. But though, by such or other means, land may continue to produce corn in long succession, much better than other crops so continued, still this is not even an exception to the general rule of the necessity for rotation. On the rich alluvial low grounds, subject more or less to freshes, where corn is usually the sole and annually recurring crop, it is true that heavy growths continue to be raised. But it is said, that in the most favorable seasons, there is a considerable proportion of rotten grain, even when not exposed to, or injured by water. These entirely rotten ears are often among the largest, and the product of flourishing stalks; and their unsound state may not be suspected until they are stripped of the enveloping shuck. This, and perhaps other inflictions of such crops, must be caused by the ravages of corn-bred and corn-sustaining insects. Yet this kind of land is not entirely without change of condition. The rank cover of weeds and grass which follow the last tillage of the corn, serves in some measure as a green shading and manuring crop. And even the inundations from freshes, which occur every year, however injurious in other respects, produce such great change of condition, that they may destroy or remove whole tribes of insects.

A stronger confirmation of this general position in regard to corn, I have learned on information from the proprietor of a piece of land in Virginia, with which I am personally acquainted. It is a large field of deep, mellow, light soil, very rich, high and level land, and so peculiarly adapted to the growth of corn, that the proprietor thought fit to keep it under that crop every year. It was so cultivated for thirteen years in succession; peas being planted with every crop, which, with such supplies as were afforded of other manure, maintained the high fertility and product of the land. But though the quantity of corn produced was not perceptibly reduced, the rotten portion (and rotten without any apparent cause) continued to increase, until it reached so large a proportion of the whole product, and the evil was of so regular occurrence, that this peculiar mode of cultivation was from necessity abandoned, and the ordinary previous plan of rotation was resumed.

But besides this important consideration, of certain tribes of destructive insects being sustained by some certain condition, and still more by the increased continued same condition of a field, and destroyed by a thorough change of that condition, such changes are better for the more complete eradication of some of the worst weeds, and still more for the better product of the cultivated crops. Plowing or stirring the soil, however necessary to be well done while the growth of a crop needs it, is hurtful to general production, if continued year after year, without cessation. Perhaps the growth of all crops may require intervals of rest and consolidation of the soil; and it is certain that some crops, which prefer a soil of firm and close texture, (as clover and wheat,) cannot be as successfully raised upon soils kept long before under tillage and hoed crops.

And while for some purposes of tillage or product, there may be required a partial consolidation of soil, others may be best forwarded by very deep and thorough working. And two crops which are peculiarly favored by the climate of South Carolina, and which are among the many great blessings of this region, serve admirably for these opposite purposes. These are field peas and sweet potatoes, which crops, extended as may be their culture already, and great their products, have not yet been duly appreciated in respect to all their benefits.

The pea crop, sown broad-cast, is an admirable rest or manure crop—giving shade, moisture and consolidation to the soil—and serving, by the sudden and great change of condition from any clean tillage crop, to remove or lessen the foulness of land, both of insect and vegetable plagues. Such I have known in my own practice, to be the highly beneficial operation of this crop, even under the much less congenial climate of Virginia; and much better must it serve in South Carolina, where not only are the climate and soil more suitable, but where the want of a crop so operating is far greater.

The length and heat of summer in this region, greatly increases the value of the pea crop. Being generally planted among the growing corn, and at a late period of its growth, the peas have enough time and sun to cover the ground well, and to mature, after the corn ceases to grow or to shade the land. This peculiar benefit of a southern climate, in regard to peas, is generally appreciated and availed of; and in this, some approach is made to an alternation of crops. Another and greater advantage, wherever wheat or oats are sown, is that the hardy black or red pea may be sown with these crops respectively, either late in autumn, or early in spring, and will often produce a good manuring green crop after the grain crop, at no more cost than the sowing of the peas. This process is, as yet, new, and so limited in extent, as to be deemed merely an experiment, of which the result is not fully determined. I know only of Mr. Wm. K. Davis, of Fairfield, and Maj. J. Littlejohn, of Union, who have, for several years, made the experiment, and so far successfully. And their object was not to use the secondary crop of peas, for what I deem its main value, that of being given to the field as manure.

These hardy and thick-skinned peas, if left on or covered in the ground, will not rot from all the cold and wet weather of winter. The danger to be feared and guarded against, is from the occurrence of a warm spell, which would induce sprouting, and consequently, the killing of the peas by succeeding cold weather. The peas grow so slowly at first, as not to be in the way of the covering grain crop; but start rapidly as soon as the latter has been removed. On September 1st, I saw a field of Maj. Littlejohn's, which had borne wheat this year, and was then under a second growth of black peas, too thin, indeed, generally, but of well advanced growth, and which promised a valuable manuring cover to the land. No seed had been sown for this crop. It sprung entirely from the peas grown there the preceding year among corn, and which, though the vines were pulled up and the crop removed as usual, from the shelled and wasted seed left on the ground, this crop was produced the succeeding year.

In the sweet potato, this country possesses a root more valuable in product, than that of any root crop of more northern climates, highly and deservedly as root crops are there prized. And potato culture, so far as it extends, ought to make an important and peculiarly valuable part of a general scheme of rotation, because of the peculiar growth of the crop, and the peculiar condition in which it puts the land. The sweet potato, though reported to draw heavily upon the soil, as do all root crops, yet, as one of the broad-leaved plants, it must draw largely from the atmosphere also; and as it can be so cheaply planted, (by slips) and easily tilled, perhaps this plant might even be profitably used as a manuring crop. But, even when the roots are removed for use, and (as usual) hogs turned in to eat the remnants, the deep growth of, and digging for the roots, also the thorough and deep rooting by the hogs, produce a condition of deep and perfect tillage, which is rarely attained in any other case, and might be most beneficially made the preparation for some other crop requiring very deep plowing and tilth to prepare for its growth.

Perennial, or other permanent grasses, of which, doubtless, there may be found some peculiarly suited to this warm climate, would still more serve to give the great benefits of changed condition to the fields, independent of the much needed benefits of grass husbandry for the feeding of live-stock, and giving rest and manure to the land. The grasses whose value has been

fully established by long experience in more northern countries, should be tried—not because they are from the north, (which in itself is a strong objection,) but merely because their good qualities are known, and possibly some of such grasses may as well suit a more southern clime. And such, I trust, is red clover, the best of all green and manuring crops. For although this was long held to belong to the north only, I have fully experienced that its locality and the perfection of its growth are fixed much more by peculiarity of soil, than by latitude. Not more than twenty years ago, it was as general a belief in lower Virginia, as now in South Carolina, that there the soil was too scanty and the sun too hot to raise red clover. But since marling and liming have made many of these soils calcareous, it is found that neither the sandy soil nor hot and dry climate forbid the raising excellent and profitable crops of clover. And so hereafter it will be found in South Carolina.

SOUTHERN AGRICULTURE.

[Extracts from an Address on the Agriculture and Husbandry of the South, delivered by Gen. JAMES HAMILTON, before the Agricultural Society of Fort Mitchell, Ala.]

Agriculture may be said to be the kind mother of us all, the source which sustains life, supports nations, and forms the *pabulum* of the commerce of the whole world. It is not surprising, that in the exuberant poetry of ancient Mythology it was deified, and that Ceres was crowned with the most fragrant and verdant garlands which grew in her own gardens, as the most propitious and blessed among heathen deities. The old Romans, who were certainly not only the greatest warriors, but the most profound politicians of their time, paid such honors to this art, that they deemed the highest praise they could accord an individual, was to say, "that he had cultivated well his spot of ground." It is a science, too, which has not been stationary for a single instant, since the moment when our first parents were ejected from that garden, "whose rich trees wept odorous gum and balm," ejected with the penalty that they should earn their bread by the sweat of their brow, though which, by the clemency of God, man has created for himself, by his own industry, a second paradise. In many of the sciences and arts, we have made no progress since the period of a remote antiquity. In poetry, Homer stands yet as an unapproachable model, whilst the statuary of Phidias is without a rival. But agriculture is daily adding to the garners of knowledge, as well as to her granaries of production.

* * * * *

Agriculture did not, however, reach the era at which it received its great and quickening impulse, until chemistry, as an experimental science, rose as its handmaid out of the mysticism of alchymy. By this science, we have learnt "the mode of investigating the composition, and studying the source from which plants derive their nourishment." By the chemical composition of manures, we have learned the true philosophy of their application, and have given to what was before vague and often unsatisfactory experiment, scientific precision and systematic arrangement.

"This great epoch of improvement received its acquisition at a comparatively recent period, from Sir Humphrey Davy's great work on Agricultural Chemistry, since which the science has been steadily progressing, and it may well be said, by its agency, we have realised the aspirations of a benevolent patriotism, by raising two blades of wheat where but one formerly grew.

* * * * *

The value of those staples we prepare for market, cannot well be over-estimated; but every good planter must look to his granary and meat house, as the source for making them, and as, indeed, the source of the solid strength of his plantation. With this view, we should ascertain the best modes of cultivating corn, potatoes and peas, and all the other leguminous and succulent plants; to gather the best means of rearing the most improved stocks, both of cattle, hogs and sheep. Nor ought we to be unmindful of the policy of raising our own horses and mules—a subject too much neglected by the Southern planter. But to accomplish all these objects, we ought to bear in mind, that the great source of production is the earth; that in order to keep her in a kind temper for yielding, we must pay her tribute without stint; that no system of agriculture is worth the expense of its maintainance, that does not look to a constant and unremitting renovation of the soil, through the judicious application of the most fertilizing manures. In this career of labor most of us are engaged, and it is for the purpose of discussing and recording the knowledge we may acquire in this our especial avocation, that this Society has been formed.

* * * * *

Having disposed of these preliminary considerations, I now propose to say something of the agriculture and husbandry of the South. I shall begin first with that staple, which is the great article of our commerce, and as it has not unaptly been called the pacificator of the world, because its necessity to the industry of the greatest belligerent in the world, holds her in check. Within the span of human life, a plant which was cultivated as an object of horticultural curiosity, has become the first of our products, and which, in its aggregate and average yield, has reached, in our country alone, the enormous amount of two millions five hundred bales per annum. By the extraordinary skill which has attended its cultivation, the production of this staple has probably exceeded the point of its consumption, and if we are not able, in the recently opened markets of China, to find vent for the surplus, prices may probably, for a time, fall below even the cost of production. It would seem, therefore, where there is an excess of production, that the policy is questionable, to treat of the best mode of augmenting the production of an already over-gathered product. But the axiom in political economy, to produce as much and sell as high as you can, applies as well to this article as any other, and although its production has greatly increased, yet a steady augmentation of the population of the world, and a consequent highly enlarged consumption of this staple will, before long, restore the equilibrium between the demand and the supply. I think it may be assumed as a postulate, that about as much cotton is produced now as can be gathered, but I am equally certain, by the improved mode of manured and checked culture, that half the land now in cultivation will give the same return. In other words, I believe five hundred acres of cotton, in the new mode of its cultivation, will produce as much as a thousand in the old. In order to embark in this recently recommended culture, it is admitted, that a large and accumulating stock of manure is necessary. It is, however, to be remembered, that the seed of one crop will nearly manure one half of the succeeding one, by resorting to the check culture, and by carefully littering and stabling our working animals and stock the whole year round, an amount of compost to manure the other half may be made. But after all, the great magazine for restoration and improvement of our soils, is at our own doors, through the region of country we occupy. Marl constitutes a never failing source of renovation. It renders porous soils more compact, and clay soils more friable, and is the most powerful agent yet discovered for decomposing vegetable matter, and converting it at once into manure. It is in this last particular it performs its most beneficial office. It has been found equally as fertilizing to cotton as to any of the cereal or root crops. Virginia has been renovated by its use. It has checked emigration in that State, doubled the product of the counties in which it has been used, and very nearly increased the price of farms in the same ratio. Yet the marl in Virginia does not average more than 60 per cent. of the carbonate of lime, its constituent element of usefulness, whilst the marl of Georgia and Alabama reaches nearly 90 per cent.—a vast difference in our favor. Let every farmer commence at once a search for that valuable mine on his farm. It is easily detected by its brown and greenish incrustation, in which are imbedded small fragments of sea-shells. Mr. Ruffin, to whom the South owes a large debt of gratitude for his researches on this subject, says, that "when any earth or stone is suspected to be marl, if it be calcareous, the easy and ready mode to test it is to apply a few drops of muriatic acid or any other strong acid. Twenty-five cents worth of muriatic acid would be enough to test thus, one thousand specimens. If no other acid be at hand, strong vinegar will serve, provided, if the specimen be very hard, it be first pounded or crushed. If the earth in question is calcareous, (as marl or limestone,) such application of acid will produce (by the disengagement of carbonic acid gas,) an immediate and violent effervescence, which it will be impossible to mistake. A mistake, however, *is* frequently made by new experimenters in this manner. If the acid (as indeed would water) be poured on dry clay, or earth not calcareous, the atmospheric air enclosed in the pores or crevices, will give place to the liquid, and escapes in air bubbles, which may be mistaken for a very slight disengagement of carbonic acid gas. The moistening of the earth with water, before touching with acid, will guard against this slight source of error. This testing by acid, decides as to what is calcareous or not, but of course does not distinguish between natural and artificial formations; and for manure, the latter, so far as they may hold out, would be just as serviceable as the former, provided they are as rich. Therefore, when the character of any earth has been tested, and found to be calcareous, the next examination needed is, (not a chemical analysis of a specimen of the first spade-full,) to ascertain whether the quantity or extent be considerable, by digging and removing the earth and applying it as manure. Nearly all the artificial deposits, (indigo vats, transported limestone, or other kind,) which I have been called to decide on, might have been dug through and exhausted in half an hour, and the most extensive of them would not have supplied a single cart for three days. Therefore, in all such cases of doubt, after ascertaining the earth to be calcareous, let the proprietor put a spade and grubbing hoe to work, and a cart if need be. The longer the supply may last, so much the more to his profit, and he will not fail to learn, either in a few minutes or a few days, whether the deposit be natural and abundant, or artificial and of course very limited in extent."

In many parts of South Carolina, where marl has been applied, the cotton crops have been nearly, if not entirely, duplicated; and although our soils are less worn than her's, it behooves us at once to commence a resort to this great mine of agricultural wealth. It ought at once to constitute an object of our Society, to obtain detailed instructions for its use and application. It is not, however, alone by the use of manures, that our cotton crops are to be increased—the great elements of solar light and heat are no less essential. Hence our cotton rows ought invariably to run south and north; that not only the least amount of shade should be cast on the plant, but that as our winds prevail in the summer months, the highest amount of atmospherical nourishment may be given to the plant. The necessity of this will be manifest, when it is recollected how much atmospherical nutrition the cotton derives from absorbents of its redundant foliage. I believe, moreover, after the full moon in July, the perpendicular stem of all cotton over four feet and a half high, should be topped, and the two or three of the long lateral branches on the full moon in August. I am satisfied that in rank and wet seasons, we should make at least one-third more to the acre by adopting this process. We have the authority of Liebig for this phenomenon in the physiology of plants. In his great work on organic chemistry, he says, "the amount of food which young plants can take from the atmosphere in the form of carbonic acid and ammonia, is limit

ed; they cannot assimilate more than the air contains. Now, if the quantity of their stems, leaves and branches, has been increased by the excess of food yielded by the soil at the commencement of their development, they will require for the completion of their growth, and for the formation of their blossoms and fruits, more nourishment from the air than it can afford, and consequently they will not reach maturity. In many cases, the nourishment afforded by the air under these circumstances, suffices only to complete the formation of the leaves and branches. The same result then ensues as when ornamental plants are transplanted from the pots in which they have grown, to larger ones, in which their roots are permitted to increase and multiply. All their nourishment is employed for the increase of their roots and leaves; they spring, as it is said, into an herb or weed, but do not blossom. When, on the contrary, we take away part of the branches, and of course their leaves with them, we thus prevent the development of new branches, an excess of nutriment is artificially procured for the trees, and is employed by them in the increase of the blossoms and enlargement of the fruit. It is to effect this purpose that vines are pruned."

In an alternation of crops, we ought likewise to look, with the occasional fallowing of our lands, as a source for their steady improvement. By a system of fallow, the lands for a thousand years, as in the vicinity of Naples, have been kept in constant heart, whilst an annual change of plants from those with, and those without surface roots on the same land, has been found to produce no deterioration in the fertility of the soil, after years of uninterrupted culture.

The same high authority to which I have just referred, (Professor Liebig,) says: "It has long since been found, by experience, that the growth of annual plants is rendered imperfect, and their crops of fruit or herbs less abundant, by cultivating them in successive years on the same soil, and that in spite of the loss of time, a greater quantity of grain is obtained when a field is allowed to lie uncultivated for a year. During this interval of rest, the soil in a great measure regains its original fertility. On the other hand it has been remarked, that a field which has become unfitted for a certain kind of plant, was not on that account unsuited for another, and upon this observation a system of agriculture has been gradually founded, the principal object of which is to obtain the greatest possible produce with the least expense of manure.

"Now it was deduced from all the foregoing facts, that plants require for their growth different constituents of soil, and it was very soon perceived that an alternation of the plants cultivated, maintained the fertility of a soil quite as well as leaving it at rest or fallow. It was evident, that all plants must give back to the soil in which they grow, different proportions of certain substances, which are capable of being used as food by a succeeding generation. But agriculture has hitherto never sought aid from chemical principles, based on the knowledge of those substances which plants extract from the soil on which they grow, and of those restored to the soil by means of manure. The discovery of such principles will be the task of a future generation, for what can be expected from the present, which recoils with seeming distrust and aversion from all the means of assistance offered it by chemistry, and which does not understand the art of making a rational application of chemical discoveries. A future generation, however, will derive incalculable advantage from these means of help."

By this improved mode of culture, through the instrumentality of a system of manuring, I believe, we may make one acre produce as much as two by the old denuded process, by which we take everything from the soil and return nothing to it. The consequences to our operatives from this mode of cultivation, by which we give to one acre the productive energies of two, are of inestimable consideration. First, one half of the horses and mules which we now use to go over an immense space of imperfectly cultivated soil, may be dispensed with, or used for the garden cultivation of a diminished number of acres. Secondly, to our slaves how greatly will the burthen be lightened, by tilling one half of the quantity of land, yet in the end having a harvest equally or perhaps even more abundant to gather? To say nothing of the increased facility of the harvest itself, by pulling two thousand pounds of seed cotton on one acre, instead of one.

At the Bend, I have this year planted in the check, twelve hundred acres of cotton—six hundred I have manured, the other six are planted in the first rise of the swamp, in a rich alluvium of untouched fertility requiring at present no manure. Two hundred acres of the former, on the second level of the swamp, are on a stiff clay flat. The cotton was planted in this field on the 1st of May. It did not receive a drop of rain until the 1st week in June. The consequence has been, that I have encountered incredible difficulty in obtaining a stand; some of the land was re-planted five times, and none less than three. It was not until the 10th of June, by unremitted efforts, I at last succeeded in setting the crop in this field. I advert to this miscarriage for the purpose of indicating its remedy, to wit: of giving a deep winter close furrow plowing, to all the clay lands you design for the check culture, and harrowing them early in the spring before you check off, after they have been rendered friable by the winter rains and frost, and another spring plowing. I believe I might have thrown up and abandoned these two hundred acres, and still that at the first level of the Bend, I will make more cotton, from present appearances, than my whole force can gather between the 15th of August and 15th of January, from manuring and adopting the check, and discarding the drill culture. On my first level, I have checked five feet by four, and on the second level, four feet square. I believe, however, five feet by three in the most fertile soils, and four by three in those of less richness, will be the right distance.

My corn on Cantey's fraction, which I think the richest piece of high river bottom I have seen this side of the Brazos and Colorado, I have planted in squares of three feet, and thinned to a single stalk. It is the best eared corn on my place, and will average, if no disaster occurs, nearly two ears to the stalk.

In noticing the check culture, I should be singularly unmindful of the claims of an individual who has most successfully directed the public attention to it, if I did not pay a willing tribute to the intelligence and ability with which he has illustrated the philosophy on which it rests. You will understand, gentlemen, that I can allude to no one but Dr. Cloud, of Macon county, who, by his careful analysis and induction of facts, has done much, I believe, to diminish the labor and augment the product of the cotton crop of the United States. That his theory rests on the true philosophy of the plant, I entertain as little doubt, as I do that its introduction will mark a new era in the culture of our beneficent staple. You will permit me to remark, that this system of manuring and planting in the check, take off half the tax on our lands, by allowing us to fallow half, or enables us to double our product in provisions and stock, if desirable. Indeed, a system of steady and efficient manuring, combined with an alternation of our crops, and of fallowing the most exhausted of our soils, constitute the best recipe for renovating an old country, and preventing a new one from growing old.

We ought to combine with this system of restoration and re-production in our soils, a most careful selection of the most approved species of stock. It seems yet to be a point undecided, whether the Holderness, Ayrshire, Herefordshire, Durham, or Devonshire breeds, are the best adapted to our climate, or whether any one of these stocks, engrafted on the common cattle of our country, would not be preferable to the unmixed foreign breed. Certainly, a cross of the Berkshire or Woburn with our common hog, is more thrifty than the full-blooded breed of either. The cattle of Alabama are so generally interior, that we propose premiums not only for the best specimens of horned cattle, but likewise for the best exhibition of any other domestic animal connected with the purposes of agriculture. Indeed, the economical husbandry of weaving our own negro cloth, of raising our own mules, cannot too soon claim our attention. On all these essential points of farming, I have made a beginning at the Bend, by the introduction of the best imported stocks; I have four different species of foreign cotton on which I am conducting a series of experiments; and a patch of sugar-cane, the syrup of which I mean to get by a new process of manufacture. The result of these experiments I desire to diffuse throughout our country, and indeed throughout the country as far as their utility can extend.

Fellow-citizens, we occupy a section of country worthy of the application of those great principles of agricultural renovation, to which I have referred. For strange as it may appear, some parts of Alabama already, young as she is, begin to put on the wrinkles and furrows of a premature old age, brought on her by the penurious barbarity of a soil-killing culture. The line of latitude, which cuts the very centre of the cotton cultivation of the new world, passes near the building in which we are now assembled. This beautiful plant bathes its blossoms in the beams of a sun, which no where shines with a more genial warmth, for its growth, development and maturity, than with us. Our soil is blessed with an Egyptian fecundity, diffused by that noble river which marches by our doors in silent majesty to the ocean—giving us a broad valley surpassed by none, if equalled by any, east of "the great Father of the Western waters." With all its affluence of soil, we must recollect, that our mother earth is as exacting as she is generous; she gives, but requires us to pay. If we fail in our tributes to her, she will fail in her donations to us. No good planter should rest quietly in his bed, except under the conviction that the spot which God has given him to till, is growing better, rather than becoming worse in his hands. This is a debt he owes to posterity, of much higher obligation than that which, by a Spanish aphorism, compels us to plant at least one tree before we die.

If we should be destined to see our great staple break down from over-production, or from any fanatic discriminations Great Britain may make in favor of what she calls, with abundant cant, free cotton, (as if she made one pound of cotton or sugar in India, but by a compulsory labor, in effect far more grievous than our own,) we still have left to us vast resources copious and untried.

I believe, without indulging in visionary projects in looking out for new staples, the experiments which have been made in Mississippi with hemp, justify the belief that we can equal the production of Kentucky in this great article of consumption; whilst the recent success of Professor Mapes, in extracting the finest quality of sugar from molasses, warrants likewise the belief, that a large profit may be realised at last by us, in the culture of the sugar cane, by the instrumentality of the evaporator which that gentleman has so successfully applied to the separation and chrystalization of the saccharine matter in molasses. We can make on our best lands, with the same facility that we can corn, five hundred gallons of the richest syrup to the acre, which would be found to hold not less than three pounds of sugar to the gallon in solution; far richer and much more easy of granulation than the molasses. I think I hazard nothing in saying, that if cotton should fall to five cents, that under the important discovery of this practical chemist, in five years all the alluvial lands on this river will be dedicated to the cultivation of the cane.

Madder is beginning likewise to attract the attention of the most intelligent of our agriculturists, as a staple adapted to our soil and cli-

mate, and susceptible of a moneyed return vastly transcending the culture of cotton.

We have everything to encourage us in our career. May the humble institution we have this day planted, tend to develope the resources of this section of our country, comparatively, even to ourselves so little known, by enlarging the sphere of our knowledge, exciting a spirit of generous emulation, and by its giving to one of the most useful arts God has given to man, something of that precision which belongs to it as a science which, from its certainty and truth, can hardly be called an experimental one.

From the American Agriculturist.

SOUTHERN PRODUCTS.

I have been a subscriber to your periodical from its commencement, and a careful reader of the various articles which have appeared in its pages, and with nothing have I been more pleased than with those communications which, from time to time, have been inserted, recommending to the attention of our farmers and planters new and valuable objects of cultivation. These communications are worthy of the most profound consideration of every cultivator of the soil. The articles on madder and indigo particularly commend themselves to attention. In a country so widely extended as ours, stretching as it does from the Gulf of the St. Lawrence *almost* to the tropics; embracing, too, every variety of climate, there can surely be found a climate and a soil adapted to almost every plant useful by its employment in the arts, or to the sustenance or luxury of man.

Every year we import largely the agricultural productions of other countries, which we might just as well, and, indeed, better raise at home. We purchase annually large quantities of olives and olive-oil from France and Italy, and figs from the Levant, and we buy many millions of pounds of tea from China. There are numerous other articles, too, of which the same remarks might be made with truth, but which do not at this time occur to my mind. The production of these articles at home is to be desired and encouraged by every well-wisher of his country; for I think it must be conceded by every intelligent man acquainted with the agricultural interest throughout the United States, that our farmers and planters have confined their attention to too few objects of cultivation. At the South, particularly, has this been the case. Cotton, sugar and rice, have been the staple articles of the Southern planters, and to the production of these have they directed their whole energies. The consequence of this has been an *over*-production; and when we consider the immense section adapted more particularly to the cultivation of cotton, it would seem that the danger of over-production in that article more especially, is yearly increasing. The same is true of the western country. The facility with which wheat, and every other species of grain adapted to the climate, is raised, is so great that there has been, still is, and under present circumstances, there must be, a production far exceeding the demand. Now the South and West are essentially agricultural regions, and for a long time must continue so; and to me it is very doubtful whether they ever become extensively manufacturing countries. At least, it will be conceded that a large manufacturing interest will not arise there, until the population becomes much more dense than it is at present. This state of things will surely increase the danger of over-production, which at present exists, and which is the true cause, in my opinion, of the low prices which we have had for a considerable time, of almost every article of agricultural produce; and these low prices must, I fear, continue, and indeed must fall still lower: for if we go on producing at the rate we have done, and are now doing, we shall not only be unable to consume our productions at home, but we shall also find it more than difficult to obtain any market abroad sufficient to absorb our surplus. To many of your readers these assertions of mine may seem not only bold but incredible, and I am fully aware that a general rise in produce has taken place during the past year. But I am satisfied of the truth and soberness of my ideas; for, as you well know, I have travelled extensively, and I have examined most of this country pretty thoroughly, and I think your own experience, gathered from long and distant travel, will bear me out in what I assert. The results of the crops throughout the country for the next five or six years will, I am confident, sustain my position.

I assume, then, that an over-production does at present exist, and will continue in an increasing ratio. Is there, then, any remedy? and if so, what is it? It seems to me that the true and sufficient remedy is to be found in extending our articles of cultivation, and extending them, too, until we raise in this country everything which our climate and our soil will permit us to raise at a reasonable profit; and it becomes the duty of every good citizen to lend his aid in accomplishing this very desirable object. But for this purpose individual effort is not sufficient. The people in their collective capacity should assist. The legislatures of the different States should do something, and do it carefully, energetically, and thoroughly. If the legislature of the nation could be induced to extend its powerful aid, it would be no more than a duty it owes to the people. But I fear that it is too much to expect from that degenerate body. At any rate, the State legislature might and could be induced to act, and their mode of action should be this. Take, for instance, the olive tree, the indigo, and tea-plants. I have no doubt that there are very extensive regions of the South exceedingly well adapted to their successful and profitable cultivation. The olive has been grown in Alabama; the indigo plant was at one time extensively cultivated in various districts of the South; and I am credibly informed that the tea-plant has been successfully cultivated to a small extent in two instances, one in North Carolina, and another on an island on the coast of Georgia. Nor is there any reason why either and all of these should not become great staples at the South; for the climate is well suited to their production, and if the cultivation should become extensive and profitable, it would not only relieve the South of the pressure of that great evil, an over-crop of cotton, by dividing the direction of the energies of the planter, but would also prove a source of increased and increasing wealth to that region.

Their legislatures, then, should act in this way. Intelligent and capable agents should be sent out to obtain information on the subject of the cultivation and preparation for market of these articles, (if such information cannot be obtained at home, and in the case of the tea-plant it cannot,) and on the return of these agents, the information they bring with them should be extensively circulated among the people; and the plants themselves should be widely distributed, and if necessary, experiments should be conducted at the public expense; and, above all, liberal bounties should be offered for the encouragement of the cultivation. In this way, the cultivation of indigo, olives, and tea, would in a few years obtain a firm foothold at the South, and her people would not only find themselves supplying our own country, but exporting to other countries. By such encouragement the silk culture has grown up and already taken firm root, and will, I may venture to predict, in a few years produce results very different from those anticipated shortly after

> "The days when we went *mulberrying*,
> A long time ago."

The present, moreover, is a most favorable time to take active measures for commencing the cultivation of the tea-plant especially, for our own country is just entering on better times, and we are about forming new and interesting relations with the Chinese. But these remarks do not apply merely to the cultivation of the olive tree, and the indigo and tea-plants, worthy as they are of the attention of the South. Numerous other articles of agricultural production might be pointed out, and will doubtless occur to yourself and your readers, to which my observation might be applied with equal truth. Let some or all of your numerous intelligent subscribers at the South investigate this subject with the attention it so well deserves, and strongly petition their legislatures to consider and act upon it; and the result, if the matter be persisted in, can hardly fail to be most important and beneficial to our Southern agricultural brethren.

I have not, by any means, exhausted this subject either in its bearing on the South, the West, or even our own more rugged and inclement North; and should you permit me again to occupy a space in your columns, I shall endeavor to point out some other and equally important considerations as connected with this most interesting topic.

In conclusion, I would fain hope that you and your numerous intelligent correspondents, will go on pointing out to us other new and valuable objects of cultivation, adapted to the different sections of our wide-spread but common country, and I trust that you will arouse the attention of the agricultural public in every way in your power, and by so doing you will oblige and interest more than one

NORTHERN FARMER.

From the Transactions of the N. Y. State Agricultural Society.

ON THE CULTIVATION OF DYERS' MADDER, AS AN ARTICLE OF AMERICAN AGRICULTURE.

(RUBIA TINCTORIA.)

BY M. B. BATEHAM, *one of the Editors of the New Genesee Farmer.*

The quantity of madder consumed annually in the United States, and imported from abroad, is perfectly astonishing to those who have given no attention to the subject. Unfortunately, our public records do not give very exact information on the subject; but Mr. Ellsworth, as the nearest approximation he could obtain, gives the amount as *five thousand tons!* Estimating this at the low average price of ten cents per lb., it makes the round sum of *one million of dollars* paid annually to foreign countries for an article that can be produced as good and as cheap at home—paid, too, by a people loaded down with indebtedness, and disgraced by the forfeiture of plighted obligation!

The cultivation of madder has heretofore been represented as a tedious and laborious operation, requiring much care and skill, as well as outlay of capital. The directions have been mainly gathered from foreign works, detailing the methods practiced by the plodding Dutch in Holland and Germany. These accounts have appeared so frightful to Americans, that none of them have dared to undertake the business; and Yankee enterprise and labor-saving ingenuity have never been exercised upon it.

It is true, the crop requires three or four years to arrive at maturity, and needs considerable labor and some knowledge; but the quantity of land it occupies, and the amount of labor it requires, is far less in proportion to the value of the crop than those of any other farm-crop that can be named.

These assertions are fully corroborated by the experience of an enterprising American farmer, Mr. Joseph Swift, of Erie county, Ohio, who has been engaged in the culture of madder for 5 years past. A detailed account of Mr. Swift's mode of culture and its results, was obtained at his residence last winter, by the writer of this essay, and published in the New Genesee Farmer for March, 1843.

From this account it will be seen, that after having informed himself on the subject, and becoming satisfied that the business was practicable and profitable, he at once planted nine acres—a quantity that would astonish Mynheer Van Hollander. This he allowed to grow four seasons, and the crop was harvested and sold in the fall of 1842. The following are some of the results of his experience. The product of his best land was at the rate of 2,000 lbs. per acre; and he is certain that, with his present knowledge, he can obtain 3,000 lbs. per acre—which is more than the best average crops of Holland or Germany. The *quality* was superior to the average of imported madder.

The labor required, including the whole time, with the digging, cleaning, threshing, &c., was from eighty to one hundred days' work per acre. The outlay for buildings, fixtures, &c., did not exceed, in all, fifty dollars.

The value of the crop was at the rate of fifteen cents per pound, at which price he sold most of it—notwithstanding the circumstance of its being unknown to purchasers, and all the prejudice that usually exists in such cases.

The result, then, in figures, fairly stated, stands thus, for an acre of good land properly managed:

By 2,000 lbs. of madder, at 15 cents per lb.,		$300 00
Contra—To 100 days' work, mostly boys, at 75 cents per day,	$75 00	
Use of land, 4 years, at $4 per year,	16 00	
Grinding, packing, &c.,	9 00	
		100 00
Leaving a nett profit per acre, of		$200 00

Mr. Swift was one of the earliest settlers of that section of the country, having resided nearly thirty years on the farm he now occupies, which consists of about 400 acres of choice land, mostly alluvial, in the valley of the Vermillion river, seven miles from Lake Erie. At my request, he furnished me with the following practical directions for the cultivation of madder, which he remarked must be understood as intended for those who wish to cultivate only a few acres, and cannot afford much outlay of capital. Those who wish to engage in the business on an extensive scale, would need to adopt a somewhat different practice.

Soil and Preparation.—The soil should be a deep, rich, sandy loam, free from weeds, roots, stones, &c., and containing a good portion of vegetable earth. Alluvial "bottom" land is the most suitable; but it must not be wet. If old upland is used, it should receive a heavy coating of vegetable earth, (from decayed wood and leaves.) The land should be plowed very deep in the fall; and early in spring apply about one hundred loads of well-rotted manure per acre, spread evenly, and plowed in deeply; then harrow till quite fine and free from lumps. Next, plow the land into beds four feet wide, leaving alleys between, three feet wide; then harrow the beds with a fine light harrow, or rake them by hand so as to leave them smooth and even with the alleys. They are then ready for planting.

Preparing Sets and Planting.—Madder-sets, or seed-roots, are best selected when the crop is dug in the fall. The horizontal uppermost roots (with eyes) are the kind to be used; these should be separated from the bottom root, and buried in sand, in a cellar or pit. If not done in the fall, the sets may be dug early in the spring, before they begin to sprout. They should be cut or broken into pieces, containing from two to five eyes each—i. e. three to four inches long. The time for planting is as early in spring as the ground can be got in good order, and severe frosts are over, which, in this climate, is usually about the middle of April. With the beds prepared as directed, stretch a line lengthwise the bed, and with the corner of a hoe make a drill two inches deep along each edge and down the middle, so as to give three rows to each bed, about two feet apart. Into these drills drop the sets, ten inches apart, covering them two inches deep. Eight or ten bushels of sets are requisite for an acre.

After Culture.—As soon as the madder plants can be seen, the ground should be carefully hoed, so as to destroy the weeds and not injure the plants; and the hoeing and weeding must be repeated as often as the weeds make their appearance. If any of the sets have failed to grow, the vacancies should be filled by taking up parts of the strongest roots and transplanting them; this is best done in June. As soon as the madder plants are ten or twelve inches high, the tops are to be bent down to the surface of the ground, and all except the tip end covered with earth shovelled from the middle of the alleys. Bend the shoots outward and inward, in every direction, put half a bushel of roots at a time and stir them about in the water, pulling the bunches apart so as to wash them clean; then, having a platform at hand, lay them on it to dry. To make the platform, take two or three common boards, so as to be about four feet in width, and nail cleets across the under side.) On these spread the roots about two inches thick for drying in the sun. Carry the platforms to a convenient place, not far from the house, and place them side by side in rows east and west, and with their ends north and south, leaving room to walk between the rows. Elevate the south ends of the platforms about eighteen inches, and the north ends about six inches from the ground, putting poles or sticks to support them: this will greatly facilitate drying. After the second or third day drying, the madder must be protected from the dews at night, and from rain, by placing the platforms one upon another to a convenient height, and covering the uppermost one with boards. Spread them out again in the morning, or as soon as danger is over. Five or six days of ordinary fine weather will dry the madder sufficiently, when it may be put away till it is convenient to kiln-dry and grind it.

Kiln-drying.—The size and mode of constructing the kiln may be varied to suit circumstances. The following is a very cheap plan, and sufficient to dry one ton of roots at a time. Place four strong posts in the ground, twelve feet apart one way, and eighteen the other; put girts across the bottom, middle and top; and nail boards perpendicularly on the outside as for a common barn. The boards must be well seasoned, and all cracks or holes should be plastered or otherwise stopped up. Make a shed-roof of common boards. In the inside, put upright standards about five feet apart, with cross-pieces, to support the scaffolding. The first cross-pieces to be four feet from the floor; the nex two feet higher, and so on to the top. On these cross-pieces, lay small poles about six feet long and two inches thick, four or five inches apart. On these scaffolds the madder is to be spread nine inches thick. A floor is laid at the bottom, to keep all dry and clean. When the kiln is filled, take six or eight kettles or hand-furnaces, and place them four or five feet apart on the floor, (first securing it from fire with bricks or stones,) and make fires in them with charcoal, being careful not to make any of the fires so large as to scorch the madder over them. A person must be in constant attendance to watch and replenish the fires. The heat will ascend through the whole, and in ten or twelve hours it will all be sufficiently dried, which is known by its becoming brittle like pipe-stems.

Breaking and Grinding.—Immediately after being dried, the madder must be taken to the barn and threshed with flails, or broken by machinery, (a mill might be constructed for this purpose,) so that it will feed in a common grist-mill. If it is not broken and ground immediately, it will gather dampness so as to prevent its grinding freely. Any common grist-mill can grind madder properly. When ground finely it is fit for use, and may be packed in barrels like flour for market.

Amount and value of Product, &c.—Mr. Swift measured off a part of his ground, and carefully weighed the product when dried, which he found to be over two thousand pounds per acre, notwithstanding the seasons were mostly very unfavorable. With his present knowledge of the business, he is confident that he can obtain at least three thousand pounds per acre, which is said to be more than is often obtained in Germany. The whole amount of labor he estimates at from eighty to one hundred days' work per acre. The value of the crop, at the usual wholesale price, (about fifteen cents per pound,) is from three to four thousand dollars. In foreign countries it is customary to make several qualities of the madder, which is done by sorting the roots; but as only one quality is required for the western market, Mr. Swift makes but one, and that is found to be superior to most of the imported, and finds a ready sale.

If any person desires instruction for making several qualities of madder, or further information respecting any other point, it may be obtained by addressing, post-paid, Joseph Swift, Birmingham, Erie county, Ohio.

From the Tennessee Agriculturist.

TO FARMERS' DAUGHTERS.

It has been sometime since I talked to the girls. This evening I will give them a few lines, letting them know I think of them yet. As usual, I am dwelling on the common, every day affairs of life, and feeling more and more the importance of young females being well acquainted with all the minutiæ thereof. The reason for my writing as I do at present, I will give you.

A few days since, I heard a gentleman, who wished a domestic, industrious, and contented wife, speaking of a pretty, interesting girl, praising her modest deportment and engaging manners; but at last, wound up with, "She does not know how to do any thing useful; she could not even make her own dresses; she would be of very little use in this world of hard work." Now, I had nearly the same opinion myself, though I would not tell him, you know; but I thought I would tell you, and let you profit by it, if you choose. He spoke also of some young ladies who studied mental and moral philosophy, chemistry, and other branches, and wanted to know what use it would finally be. He was certain, from his own observation, they did not have enough of philosophy to govern their tempers and general conduct; and as to chemistry, all their study of it had not given them a knowledge of bread-making, which he considered a very important item, his mother having been successful in that line of business, and he had been accustomed to the best sort of bread. He thought, if their studies were not of some practical utility, they might as well be let alone.

I was really amused, to hear views so much in opposition to the prevailing notions of the day; and, to tell the truth, I thought there was some good common sense in them, though I informed him the girls would laugh most heartily at such nonsensical stuff, in these days of improvement, when many consider it polite and sensible to be perfectly ignorant of common affairs. My advice was, that he should go away out in the country, and look for the daughter of some good farmer, who had taught his family that it is honorable to engage in all the useful employments in which the greater part of the duty of woman consists—one who could sit down happily at home, and study household good, without sighing for the excitement of fine dress, fashionable furniture, fashionable visits, and all those fashionable things that disturb the peace of young housekeepers, and render home a scene of misery and strife, instead of the gathering place of the heart's best affections.

If girls had any idea of what would promote their future happiness and interest, more of their precious time would be spent in the acquisition of useful and necessary knowledge, rather than frittering it away to gain a few (generally useless) accomplishments. The first is of great importance, in every situation of life; the latter are almost always given up, as soon as their possessor takes her station at the head of a family. I was led to consider what should be the character of a lady who has finished her education, or who at least has left school, and also of the training necessary to form that character.—Nothing preventing, I will tell you my cogitations at some future time, although some of you will think I am altogether too old-fashioned to be writing in these days of light and knowledge.

LUCY.

Agricultural Curiosity.—A friend has given to us a natural curiosity, as the product of a corn stalk. It is a main ear with thirty five lateral shoots, or small ears, most singular interwoven into each other, forming a handsome group, which might very properly be called a bouquet of ears. It was grown in the corn field of Mr. Diffenderffer, near Lancaster, Pa.

For the Southern Cultivator.

AUGUSTA, August 7th, 1844.

MR. EDITOR—I send you the copy of an extract, in the American Journal of the Medical Sciences, published in May, 1827.

M. Charles Garou de Buzareingues was a correspondent of the Institute of France. His experiments and observations were published originally in 1827, in Magendie's Journal of Physiology, Experimental, &c., vol. VII. This article was copied into the London Medical and Physical Journal, in February, 1828, whence it was taken by the Editor of the American Journal of the Medical Sciences.

There is no reason why it should not apply as well to other animals, as to those therein enumerated.

"A flock of sheep was divided into two equal portions, and a smaller or greater number of male or female lambs were to be produced, at the will of the proprietor, in each of these. The plan adopted in order to ensure this result, was to employ very young rams in that division of the flock from which it was designed to obtain females; and strong and vigorous rams, of four or five years of age, in that from which males were to be procured. The first division was also recommended to have a more abundant supply of food, and more repose than usual, during the period of impregnation. The following table will show the effect of the first experiment:

Age of the Mothers.	Males.	Females.
2 years,	14	26
3 years,	16	29
4 years,	5	21
5 years and upwards,	18	8
Total,	53	84
At another farm—		
2 years,	7	3
3 years,	15	14
4 years,	33	14
5 years,	25	24
Total,	80	55

"Another experiment is thus related:—A flock of 106 sheep was divided into two sections of forty-two each; one containing the strongest ewes, of four and five years of age—the second, consisting of the weakest, either less than four or more than five years old: the first section was intended to produce a greater number of females than the second; and, after having been marked and placed in a good pasturage, four rams, of about ten months old, were turned into them. The other section received two strong rams, each aged more than three years. The remainder of the flock, making up the number of 106, belonged to the shepherds; they are generally stronger and better nourished than the rest—and these, forming a third section, were placed under circumstances similar to the second.

"The result of the lambing was thus:—

	Males.	Females.
First section,	15	25
Second section,	26	14
Third section,	10	12

There were four double births; two of which, in the first section, produced 4 females. The two others, belonging to the second and third sections, produced 3 males and 1 female.

"It is to be remarked, that the rams proceeding from the section in which the young rams were employed, were in all respects as fine as those begotten by the older and stronger rams.

"In connection with this part of the subject, we find, in another part of the communication, a remark of some importance. In 1825, twenty ewes, which had not borne for two years, received the rams clandestinely in the beginning of the winter; they were almost all of them remarkably fat: they produced 16 females, and 4 males. Among the number of these ewes were 2 old ones, which had been put up to fatten in 1824, but could not be sold because they were not in sufficiently good condition; these gave 1 female, and 1 male.

"M. Garou next carries his inquiries into the productive power in the mare and cow. Respecting the first of these, he observes that, wishing to obtain more female than male colts, he fed his brood mares on fresh food; and he chose for propagation only such as had not been foaled or even nourished by the mother the preceding year; and he did not give them the stallion until they gave evident signs of being in heat. Five mares, so chosen, produced five female colts; and, by following the same method, out of thirteen colts foaled that year, eleven were females; and one of the two males was the product of an old mare. He remarks, that some mares of a remarkably vigorous appetite, always bring forth females; whilst those of delicate health as constantly produce males. The same remarks apply to the cow."

From the Western Cultivator.

PICKLES.

Accompanying I send you a few extracts, on the best methods of putting up pickles, as the time of year is approaching for this to be attended to.

"Musk-melons should be picked for mangoes when green and hard. They should be cut open after they have been in salt-water ten days, the inside scraped out clean, and filled with mustard seed, allspice, horse-radish, small onions, &c., and sewed together. Scalded vinegar should then be poured upon them.

Walnuts.—When these are so ripe that a pin will go into them easily, they are ready for pickling. They should be soaked twelve days in very cold and strong water, which has been boiled and skimmed. A quantity of vinegar, enough to cover them well, should be boiled with whole pepper, mustard seed, small onions, or garlic, cloves, ginger, and horse-radish; this should not be poured upon them until it is cold. They should lie in pickle a few months before they are eaten. To be kept closely covered, for the air softens them. The liquor is an excellent catsup to be eaten on fish.

Peppers.—Put peppers into strong salt and water, and let them remain there till they become yellow; then turn them green by keeping them in warm salt-water, shifting them every two days. Then drain them, and pour scalding vinegar over them. A bag of mustard-seed put in the jar is an improvement. If there is mother in the vinegar, scald and strain it.

Cucumbers.—Cucumbers should lie in weak brine three or four days after they are picked; then they should be put in a tin or wooden pail of clean water, and kept slightly warm in the kitchen corner for two or three days; then take as much vinegar as you think your pickle-jar will hold—scald it with pepper, allspice, mustard-seed, flag-root, horse-radish, &c., if you happen to have them: half of them will spice the pickles very well. Throw in a piece of alum as big as a walnut; this serves to harden the pickles. Skim the vinegar clean, and pour it scalding hot over the cucumbers. Brass vessels are not healthy for preparing any thing acid.

Red Cabbages need no other pickling than scalding, spiced vinegar poured over them, and suffered to remain eight or ten days before you eat them. Some think it improves them to keep them in salt and water twenty-four hours before they are pickled.

If you find your pickles soft and insipid, it is owing to the weakness of the vinegar. Throw away the vinegar, (or keep it to clean your brass kettles,) then cover your pickles with strong, scalding vinegar, into which a little allspice, ginger, horse-radish, and alum have been thrown. By no means omit a pretty large piece of alum. Pickles treated in this way, will keep for years, and be better and better every year.

Some people prefer pickled nasturtion-seed to capers. They should be kept several days after they are gathered, and then covered with boiling vinegar, and bottled when cold. They are not fit to be eaten for some months.

Martinoes are prepared in nearly the same way as other pickles. The salt and water in which they are put, two or three days previous to pickling, should be changed every day; because martinoes are very apt to become soft. No spice should be used but allspice, cloves and cinnamon. Scald the martinoes and spice in the vinegar, instead of pouring it over them."

POINTS OF A GOOD MILCH COW.

The following is from a report of the Guernsey Agricultural Society.

1. Purity of breed and qualities of the dam for yielding rich and yellow butter.
2. Small head, large and bright eyes, small muzzle, small ears, orange color within.
3. Straight back from the shoulders to the tail, and chest wide.
4. A fine and loose skin, with soft and short hair.
5. Sides well rounded, flank small between the side and haunch, tail fine.
6. Fore-legs straight and well proportioned, hind-legs broad above the knee, fine and clean below; hoofs small; legs should not cross in walking.
7. Udder large, and the teats large, and springing from the four corners of the udder; milk-vein large and well-defined.

From the Albany Cultivator.

AMUSEMENTS FOR FARMERS' BOYS.

Being lately at the residence of one of our most intelligent farmers, our attention was attracted to the door of a small room in an outbuilding, which was labelled "—— office." On inquiry, we learned that this was a room given up to the boys. Entering, we found it fitted up with miniature implements of husbandry, seeds of different kinds, a few plants, and branches of ever-green, the walls decorated with portraits of celebrated horses, cattle, sheep, swine and poultry; while on some shelves, were some geological specimens, and several juvenile books of a character calculated to inspire a taste for rural life, and at the same time to teach correct modes of husbandry, horticulture, &c., the whole arranged in agreeable order. It struck us as an excellent plan, and we would suggest its general adoption. It furnishes the means of both amusement and instruction.

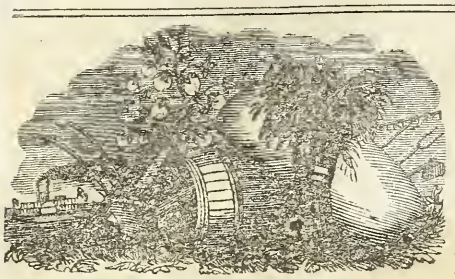
How infinitely better it is to allow boys an opportunity of spending a part of their time in thus cultivating a taste for the investigation of those subjects by which their knowledge of nature and the world around them is increased, than in mixing with rude company and becoming contaminated with their vices.

RURAL EMBELLISHMENTS.

I have said and written a great deal to my countrymen about the cultivation of flowers, ornamental gardening, and rural embellishments; and I would read them a homily on the subject every day of every remaining year of my life, if it would induce them to make this matter one of particular attention and care. When a man asks me what is the use of shrubs and flowers, my first impulse always is to look under his hat and see the length of his ears. Heartily do I pity the man who can see no good in life but in pecuniary gain, or in the mere animal indulgences of eating and drinking.—*Colman's European Agriculture.*

TALL CORN.—A down-easter recently told a citizen of the "Lone Star Republic," that nothing could beat the corn in Connecticut. The Texan replied that he knew nothing of the crops in that section, but in his country the cornstalks bore seven or eight large ears, and a gourd on top with several quarts of shelled corn in it! The Yankee took his hat and marvelled.—*Selected.*

☞The Southern Farmer and Gardener says that, by an experiment recently made, it was ascertained that clover and timothy seed would cease to germinate at the depth of two and a half inches.



WEDNESDAY, AUGUST 21, 1844.

☞"A Burke Overseer" has exhibited too much feeling in his reply to "A Burke Planter," to gain admission into our columns. Our object in publishing the "Cultivator," is to elicit truth and diffuse light upon all and every subject connected with agriculture; and, as these are not likely to be accomplished by a heated or excited discussion, we will not permit such in our columns. While, therefore, we shall take great pleasure, at all times, in giving place to temperate discussion upon all subjects, and on none more cordially than that of overseers, we hope our readers will approve our determination to exclude whatever is calculated to engender ill feeling.

☞It is estimated, by the Vicksburg Constitutionalist, that the destruction of property by the recent floods will amount to over *twenty millions of dollars*. The loss of cotton is said to be at least 450,000 bales, or nearly one-fifth of the whole crop of the United States.

☞A late letter from England to a house in Boston, states that vessels are in great demand —not less than 700 to 800 being engaged in the Guano trade alone.

☞As many planters in our own State bestow an undue share of their attention upon their cotton fields, to the neglect of corn and other provisions, and thus, as we think, pursue an injudicious system of husbandry, we commend to the perusal of such the following extract from Ruffin's Agricultural Survey of South Carolina.

"It is a common opinion, that the cultivation of rice and cotton is much more profitable than that of corn and other provisions, and that those planters having good lands for the former, can better afford to raise them, and buy provisions in part, or corn, sometimes, entirely. This opinion seems to me erroneous, almost without exception. It seems next to impossible, that there can exist, anywhere, a truly thriving agricultural class, which, as a regular system, buys, instead of raising, the necessary and most important articles of food. Such a system, pursued by the proprietors of rich rice and cotton lands, may indeed present large incomes of money for crops sold; and it may minister to encourage great luxury and expenditure. But it will be apt also to induce a pinching measure of the plain and solid comforts, and even in respect to necessary wants, and a scant provision of proper supplies of aliment to man and beast, and also to the land. A thorough reform on this head, to be produced by the sufficient diminution of each individual's rice and cotton culture, and substitution of extended corn, and other provision culture, and grass and stock raising in general, is essential to the permanent, solid, and agricultural prosperity of the State."

☞It is easier to bring up a dozen children right, than to reform one grown scamp. Many have learned this too late to profit by it.

☞Hungarian Yeast, says an exchange paper, will keep for a twelvemonth. During the summer season, they boil a certain quantity of wheaten bran and hops in water—let it ferment. When this has taken place, throw in sufficient of bran to form it into a thick paste, which they make into balls, and dry by a slow heat. When wanted for use they are broken, and boiling water is poured upon them.

THE GLANDERS.

Mr. J. B. Cook, in the Albany Cultivator, says: "Whilst writing, I will mention a fact for your veterinary department. More than thirty years since, the glanders of the most virulent kind, was amongst the horses of the neighborhood in which my father lived. Great numbers died off. His horse was affected, and under the belief that he also would die, my father commenced an experiment on him with a strong decoction of tobacco juice given internally. In a short time the horse broke out all over his body in sores. These cured up in a month or so, and the horse was sound, soon fatted, and was, as long as I knew him afterwards, a sound and healthy animal. This was the only horse in all the neighborhood that recovered. Some farmers in this vicinity, noted for fine sleek horses, occasionally give Scotch snuff to them."

A NEW PUDDING.

We yield to no man in our admiration of Indian Corn, and the various culinary purposes to which it is applied. But here is one of a nature rather novel to us, but we should not fear to endorse it upon the authority of the recommendation of Prentice, of the Louisville Journal, whence we clip it:

One of the very nicest things ever brought to the table, in the pudding line, is the green corn pudding, prepared according to the following recipe. Let every wife, who would like to surprise her husband by a rare delicacy, try it.

Take of green corn twelve ears and grate it. To this add a quart of sweet milk, a quarter of a pound of fresh butter, four eggs well beaten, pepper and salt, as much as is sufficient; stir all well together, and bake four hours in a buttered dish. Some add to the other ingredients a quarter of a pound of sugar and eat the pudding with sauce. It is good cold or warm, with meat or sauce; but epicures of the most exquisite taste declare for it, we believe, hot, and with the first service.

It is said that there are some folks who write, talk, and think so much on virtue, that they have no time to *practice* it.

To raise young turkeys, wet their food with sour milk, and let them have free access to a vessel of sour milk for drink. Use corn meal for their food. So says the Prairie Farmer.

Comparative Nutriment of Food.—110 lbs. of wheat contain 85 lbs. of nutritious matter; of rice, 90 lbs.; of rye, 80 lbs.; of barley, 83 lbs.; of beans, 89 to 92 lbs.; of peas, 93 lbs.; of meat, average, 35 lbs.; of potatoes, 25 lbs.; of beets, 14 lbs.; of carrots, 14 lbs.; of greens and turneps, 8 lbs.; of bread, 80 lbs. Indian corn is about next to wheat. A pound of bread contains more than double the nutriment of a pound of meat; and seven pounds of potatoes are equal to five of meat.

Sow millet one bushel to the acre; cut it as the seed begins to turn yellow; cure it as other hay. Horses or cattle prefer it to clover or timothy. It matures in two months. Sow from April to August.

MANURES.

The following communication upon this important and very interesting subject, from a highly esteemed correspondent, has reached us just on the eve of going to press, and we give place to it in preference to any speculations of our own.

For the Southern Cultivator.

Mr. Editor—In the early settlement of the lands in Georgia, the soil was sufficiently fertile for the farmer to make as much produce as his wants required, or he was willing to harvest. But, by continued cropping, lands became exhausted, because each crop takes from the soil some of the elements that enter into the composition of all plants. Such is the case with many of the lands in this State, and most of them are approximating a state of barrenness. It then becomes the interest and the duty of every farmer, to look out for a remedy to stop the wearing out of his lands, and the best method of restoring them to their original fertility. Each and every part of the State should study out its own resources, and apply them to the improvement of the lands. The Northwestern part of the State has lime; some of the Southern counties have lime and marl: while in the middle counties, we shall have to rely upon such manures only as we can make on our farms. Colonus, in his excellent remarks on manures, has nearly occupied the whole subject, when he directs manure to be obtained "from everywhere." Every one will have to make and gather manure on his own farm, the best way he is able—and those who commence first, will acquire the most skill and knowledge in making and applying manures.

Those manures that most naturally present themselves to the notice of the farmer, are green manures, or vegetable matter in the green state. The plowing under green crops sowed for the purpose, or green weeds or grass, that grow spontaneously upon the land, has been practised in some countries with great advantage. Professor Johnston says, "the plowing-in of green vegetables on the spot where they have grown, may be followed as a method of manuring and enriching all land, where other manures are less abundant. Growing plants bring up from beneath, as far as their roots extend, those substances which are useful to vegetation, and retain them in the leaves and stems. By plowing in the whole plant, we restore to the surface what had sunk to a greater or less depth, and thus make it more fertile than before the green crop was sown. This manuring is performed with the least loss by the use of vegetables in the green state. By allowing them to decay in the open air, there is a loss of organic and inorganic matter: if they be converted into fermented (farm-yard) manure, there is also a large loss—and the same is the case, if they are employed in feeding stock, with a view to their conversion into manure. In no other form can the same crop convey to the soil an equal amount of enriching matter, as in that of green leaves and stems. Where the first object, therefore, in the farmer's practice is so to use his crops as to enrich his land, he will soonest effect it by plowing them in the green state."

Thus we have found one source of enriching our lands within the reach of every farmer. Those green vegetable substances, best suited for manure, are such as derive most of their sustenance from the atmosphere; while in the growing state, such as corn-field peas, &c.; clover, wheat, rye, barley, oats, and Indian corn, are all used for soiling—grass and weeds also afford excellent manure.

Green vegetable substances should be plowed under before they begin to form seed. Dry vegetable substances are usually placed in the manure yard—and after they are partially trodden to pieces, are taken up, spread broad-cast on the fields, and plowed under. Others take up the manure, place it in pens, and suffer it to ferment and decompose, and form what is called short manure—which is applied in the hill or drill. There is less loss in the first method. There is one kind of valuable manure which is almost entirely lost to Southern farmers. Professor Johnston says, that the recent urine of one cow, in one year, contains 900 pounds of solid matter, yielding 226 pounds of ammonia; which, in Flanders, is valued at $10 a year for manure, which is the value of an ordinary cow in this State. Though there is no doubt, the solid and liquid manure of cattle will be varied by the quantity and quality of their food. In order to save such manures, stables and cow-houses must be constructed, with drains and reservoirs to receive the liquid manures.

The above is mentioned to show the value some place upon manures.

In preparing cotton-seed for manure, there is no doubt but a large portion of the manure is lost by evaporation. No person can pass a pen or pile of cotton-seed, while it is rotting, without smelling the gas that escapes from the seed. By covering the seed with soil ten or twelve inches deep, the dirt will absorb the gas, and become good manure itself.

I have, Mr. Editor, mentioned some of the manures which are within the reach of all Southern farmers—and it is hoped they will no longer delay to make and use them on their lands. PLOWMAN.

NEW COTTON.—In New Orleans on the 10th instant, 54 bales of the new crop had been received. The first load of new Cotton seen at Columbia, S. C., was sold there on Saturday last. It brought 7¾ cents per pound.

NOVEL HOT-BED.---It is stated in the report of the Midland Mining Commission, that near Dudley, in Staffordshire, early potatoes are raised for the London market in ground heated by the steam and gases emitted from an old colliery which has been on fire for many years. This is a much more direct and economical application of internal heat than that proposed by our Parisian neighbors, who are at present laboring to procure naturally heated water from a depth of 3000 feet wherewith to warm the greenhouses and menageries of the Garden of Plants---presuming that water from that depth will be raised to 100 or 104 degrees of Farenheit, by the central or internal heat of the earth.---*Chambers' Jour.*

A SALUTARY RESTRICTION.---The Government of the principality of Waldek, in Germany, have given public notice that no license to marry will hereafter be granted to any individual who is addicted to drunkenness; or, if having been so, he must exhibit full proofs that he is no longer a slave to that vice. The same Government have also directed that in every report made by the ecclesiastical, municipal, and police authorities, upon petitions for license to marry, the report shall distinctly state whether either of the parties desirous of entering into matrimonial connexion is addicted to intemperance or otherwise.

From the Rochester Democrat.

AWAY TO THE WOODLAND.

BY J. D. REID.

Away to the woodland, away to the stream,
Where the merry stars on its bosom beam!
How swift from the city's dull smoke we fly,
That shadows the glance of this laughing eye!
My head aching,
My bones are sore,
And joy awaking,
Can wait no more.
So off to the woodland, away to the stream,
Where the merry stars on the water beam!

Oh! who would live always from the breeze,
That flesh o'er the fountain trips over the trees?
Where the green grass bends to the merry lamb,
As it skips and bleats by its woolly dam?
Whew! snap the fetter!
Come, pony, go,
Where oats are better,
And parsnips grow!
Away to the woodland, and down by the stream,
Where the merry stars on the waters beam!

We will strip the cress from the babbling brook,
We'll sipple the cream in its stealthy nook!
And the richest herbs and the purest air,
Shall soon be our morning and nightly fare!
Quicker and fleeter,
Come, pony, haste,
Where hay is sweeter,
To pony's taste!
Down by the woodland, away by the stream,
Where the merry stars on its bosom beam!

I hear the plow o'er the mellow ground,
And the distant cowbell's clinking sound;
And the buzzing wheel, and the echoing stroke
Of the bushman's axe on the "brave old oak."
On his proud domain
The rooster crows,
As he picks the grain
Where the plowboy goes.
Near a sweet little cottage, down by the stream,
Where the merry stars on its bosom beam!

I could not live alway away from the churn,
Where the oceans of cream to buttermilk turn;
Down in the city, its dust and its din,
Where men are so noisy and milk is so thin!
Fleeter, oh! fleeter,
Come, pony, go,
Where birds sing sweeter,
And pumpkins grow!
Away by the woodland, and down by the stream,
Where the merry stars on its bosom beam!

Grey Squirrels.—A correspondent of the Philadelphia North American, writing from the borders of Lake Champlain, confirms a statement made by Dr. Morse in his well-known geography, and which has by some been regarded as fabulous. He says:

"A word on the instinct of the squirrels here. When they wish to move from one island to the other, they watch the wind till it blows in the right direction, and then you will see them in dozens coming to the beach, each with a large piece of bark in his mouth, which he launches, then jumping on board turns up his tail for a sail, and over he goes to the port of his destination. I might have shot them while making sail, but it looked to me as something almost wicked."

Singular Incident.—During the run of the ship Phœnix, from the Island of St. Helena to this place, an African locust flew on board, which was caught and preserved. The distance of the vessel at the time, being one thousand and thirty miles from the continent of Africa, and a still greater distance from that of South America Query—What did the little navigator subsist on during the voyage?—*Sag Harbor Corrector.*

BACON'S LARD LAMPS.—A new article, superior to all others for this purpose, emitting a good clear light without smell or smoke, and at an expense, counting Lard at 8 cents a pound, of about a quarter of a cent an hour.

These Lamps have been satisfactorily tested, and are recommended as "just the thing" for the use of planters. and all others who study utility, neatness and economy.

A supply of the above Lamps, with Fillers and Wicks for them. For sale by

HAVILAND, RISLEY & CO.

jy 24-d,c&Cultf

TURNEP SEED.

A SUPPLY of the following varieties of fresh TURNEP SEED just received, viz:

Yellow Sweedish or Ruta Baga, very fine for stock,

Large Globe Turnep, } Fine
" White Flat do. } for
" Hanover or White Ruta Baga do } table
" Norfolk do. } use.

For sale in quantities to suit purchasers, by

Aug. 30 18-tf WM. HAINES, JR.

GARDEN AND FIELD SEED.

A GENERAL assortment of fresh and genuine GARDEN and FIELD SEED, among which are the following:

Red and White Clover,
Blue and Green Grass,
Rye and Orchard do.,
Timothy and Herds do.,
Millet and Lucerne do.,
Seed Corn of every valuable variety,
Seed Wheat,
Buckwheat and Potato Oats,

Kept constantly on hand by the subscriber, all of which are offered for sale at very moderate prices. All orders, by mail or otherwise, executed with neatness and despatch.

SOUTHERN CULTIVATOR.

VOL. II. AUGUSTA, GA., SEPTEMBER 4, 1844. No. 18.

From the N. E. Farmer.

THRIFTY AND UNTHRIFTY FARMING.

FRIEND BRECK—I recently made an excursion of some distance in the country, and tarried for a short time in a farming community, where the first eighteen or twenty years of my early days were spent. Many years have elapsed since, and other pursuits have engrossed my time and attention. Yet, often my mind reverts to the scenes of youth, and memory rolls back the recollections of other days, when, in common with all the rural community in which I resided, I felt all the joyous hope of seed-time, entered with zeal into all the labors and excitement of haymaking and harvest, and shared in all the frolic and glee of husking parties; and in all the thoughtlessness and buoyancy of youth, looked forward for thanksgiving, as the very best of all the days in the year.

In visiting the place, after an absence of twenty or more years, I found many striking changes had taken place: many an honest, brawny-limbed farmer, then lord of his broad acres, now occupies but his six feet by two, in the "auld kirk yard;" and others that were then in the vigor of manhood, and had been spared, were bowed down with age, and their thick locks had been plucked by the fingers of time, or silvered o'er by the frosts of 70 or 80 winters. Many of my schoolmates who were then wild and reckless youths, with whom I had an hundred times tried the "tug of war" at *long hold* and *side hug*, were now staid and steady farmers—heads of families engaged in all the business scenes of life. And of the bright-eyed, flaxen-haired lasses, many were transformed to sober and careful housewives and mothers—and others were quietly sleeping the slumber that knows no awakening, most of whom had been carried off in all the bloom of youth and early womanhood, by that scourge of New England—consumption.

But as the whole country was covered with snow, I could not make much of an agricultural survey; but upon inquiry, I learned that many farms had, from bad management and culture, very much deteriorated, and greatly lessened in value; others had held on the even tenor of their way, and wintered about the same number of cattle they did formerly, and some few in the hands of enterprising, intelligent farmers, were advancing with a sure and steady pace, that would yearly add to their value, and to the wealth of their owners.

There had been several causes in operation to exhaust the first named class of farms—such as plowing the lands in the autumn, where much of the finer portion of the soil was blown off by the winds, and washed by the rains and melting snows, and suffering their cattle to roam over their mowing fields, both fall and spring, with a reckless waste of their manure.

In conversation with one of those farmers, (a Mr. G.,) whose farm had run backwards, I suggested to him the idea of collecting the leaves and decaying vegetable matter from a piece of woodland near by. "Why," says he, "I haint much opinion of this vegetable matter—'tis sour stuff: only give me dung enough from the hovel windows, and I can raise as good crops as Mr. I. does, with all his swamp muck, lime, compost and book-farming." I inquired if he took an agricultural paper. "No," said he—"I did take one several years ago, and that had so much to tell about a new kind of potato, that they sold for twenty-five cents a pound, and after all, it warnt no better than the long reds; and about tree corn and mulberry trees; and a good many farmers got bit, by believing their great stories, that I got sick of, and stopped it, and would not now take the gift of one."

I afterwards called upon Mr. I., the "book-farmer," as Mr. G. sneeringly called him, and found him a middle-aged, intelligent farmer, who was quietly improving his farm by every means within his reach. I was so much interested in his management, that I thought I would attempt to communicate an account of it to the public, through the columns of your useful journal, with the hope that other farmers might be benefitted by his example.

Upon looking into his barn, I found his hovel floors were water-tight, and sloping toward the back side. In the rear of the cattle, was a kind of trough of the width of 12 or 15 inches, made by sinking one of the floor-planks two inches; this was also water-tight: the droppings from the cattle mostly fell into the trough, and by giving the cattle a good bedding of litter every night, they were kept comfortable, and nearly as clean as when at pasture. He had the past winter used several loads of saw dust from a shingle mill, and leather shavings from the currier's, for the purpose of bedding, and soaking up the urine. The hovels were daily cleared out by wheeling the manure and litter into the centre of the yard, (which is dishing,) and piling it up in a snug heap. His barn is so situated he cannot dig a cellar under it, but intends the coming season to build a shed for the purpose of keeping his manure under cover for the future. The floors of his horse-stable are tight; every day it is cleared, and the manure and litter is spread under a shed, and by being trodden by his stock, it does not heat and fire-fang, as is too often the case. Most of his winter manure will be mixed with swamp mud, to compost through the summer. I inquired respecting a heap near his barn: he said there were two cart-loads of lime-mortar, that he bought for a trifle, of a man who had taken down a large house; it was mixed with about four loads of brake-root turf, about 18 months ago; it had been left this length of time for the purpose of having the plaster come to pieces, and rotting the turf. Last fall it was shoveiled over, and two lime casks of fleshings, procured at the tanner's, mixed with it. He thought while this animal matter was decomposing there would be a large amount of nitrogen generated, and give him a large amount of nitrate of lime by spring, when it would be again shovelled over, and 35 bushels of good ashes mixed, and then applied to an acre and a half of ground, upon which he should sow wheat: I think he said the compost was to be put on after the ground was plowed, and to be harrowed in with the wheat. The ashes he had purchased at ten cents per bushel

He had a cartload of the waste wool, or flyings, from the wool carder's; this was to be boiled for a short time in lye, to cleanse the oil and grease, and to render the wool more decomposable. By way of experiment, a part of it would be used to manure some of his corn and potatoes in the hill, the rest would be mixed in the compost heap, to remain a year or so. He also had a large quantity of old woollen rags, that he bought of a store keeper for a trifle—having, he said, read in some book, that 100 lbs. of woollen rags contained as much nitrogen as 3000 lbs. of cow manure. Some of these rags were to be chopped up and steeped in urine for a few days, then to be partially dried and sprinkled with gypsum, and used as manure in the corn and potato hills; the other part would, like the waste wool, be composted. He had a number of casks of fleshings that were obtained at the tanners, which would be mixed with vegetable mould as soon as the snow was off, and he could obtain it; he has also taken the hair, lime, and piths of horns from the tan-yard; the bones are broken up by the hammer and mixed with manure and plowed in; they will slowly decompose, and supply phosphate of lime to his land; he had about two barrels of the settlings of salts from the pearlash factory—similar, he thought, to the material known as glass factory manure: an account of its use and value is given in Mr. Colman's Fourth Report, pages 344--5, by a Mr. Jarvis. There were a few inches of lye upon the top of the salts in the barrels, so strong as to float an egg with nearly one half its surface above the lye. This, he assured me, according to Mr. Jarvis's statement, would convert 10 or 15 loads of loam or muck into a compost equal to the same amount of good stable manure. All these materials, sawdust, wool, fleshings, hair, lime, piths of horns, and salts from the potash, he had for removing, as they were considered a nuisance, and of no value by the manufacturers or owners. The droppings of the fowls are occasionally scraped from the boards, over which the hens roosted, and put in old casks; in the spring it will be moistened with urine and ground to pieces with a hoe, and mixed with plaster of Paris, to be applied to grass land, or put about the corn an potato hills, at the first or second hoeing; he styles it "Yankee guano." He has a strong tight box under his back house, in which is frequently thrown gypsum, or charcoal dust obtained from the coal-pen of the village blacksmith: it absorbs the smell, and once in a week or two, the contents of the box are mixed with dry peat or sawdust, or some other material, to absorb the liquid part, and put into old tight barrels. This is home-manufactured *poudrette*. His hog yard is of good size, has been dug to the depth of 18 inches, and a good plank floor over the whole, which makes it easy shovelling out the manure. The suds from the wash are conveyed to it by a spout, which, with the manure of his hogs mixed with the loam, muck, and other materials, make many loads of vegetable manure. He has tried many experiments that he has seen recommended in the agricultural books and papers that he has read; he says, after he became one and twenty, he did not feel obliged in all things to follow in the "footsteps of his worthy predecessor," his father, and sometimes pursued a new track, and went upon his own hook. He intends getting a small quantity of guano and ground bones the coming spring, for the purpose of testing them by the side of other manures. Several of the kinds he has not yet tried, but from his remarks, I feel satisfied he will find them all invaluable helps for increasing his crops, and from the nature of some of them, valuable and permanent improvers of his soils.

Salem, April, 1844.

From the New England Farmer.

ROOT CULTURE—ROTATION OF CROPS—DEEP PLOWING.

We have as yet seen no writer disputing the necessity or utility of *manuring land* to keep up or increase its fertility; but it would not greatly surprise us if some one, to show his superior sagacity, *did* shortly attack this (generally considered) *settled* point in agriculture.

In one agricultural paper, we find some writer attacking *root culture*; in another, we see the doctrine of *rotation* assailed; and in another, some one, bolder than the rest, attempts to show that *deep plowing* is a "humbug"—or not what it has "been cracked up to be"—in fact, that it is detrimental to the farmer's interest.

Upon the first of these topics—root culture—we are aware some difference of opinion exists among farmers—and *good* farmers, too. We confess ourself on the side of the roots. We have cultivated them to a considerable extent—carrots and ruta baga especially—and our experience in their use has highly commended them to our favor. There is this advantage in roots, (aside from others,) which we consider of much importance: they enable us to get rid of a good deal of coarse fodder, by being mixed with it, while upon such feed the stock thrive as well as if kept on the best hay. We cannot join with those who think root culture unprofitable, though we have a high respect for the judgment of some who hold this opinion.

The expediency of a *rotation of crops* is also called in question, and by some seemingly ridiculed. In the article headed "Change of Crops," copied into last week's Farmer, a case was cited in disproof of the necessity of rotation, where rye had grown well on the same land 27 successive years. Now, the mere fact that a particular soil gives a good crop of one kind for many successive years, is no very conclusive proof to *our* mind, that the *principle* of rotation is not sound and well founded. We were once shown a field bordering on the sea-shore, which we were informed had continued to give excellent crops of grass yearly for 26 years, without the application of any dressing. Such instances are rare, and can only be regarded in the light of "exceptions to a general rule." Why, it is to this principle of rotation, judiciously carried out, that many of the English farmers mainly ascribe the great improvement which they have effected in their husbandry; and in our own country, where the proper "course" has been adopted the rotation system has been found not only an improvement upon old customs, but one of the most important aids which the increased wisdom of the world has given to agriculture.

Rotation of crops is one of the most prominent features of the improved system of husbandry. Under the old method of farming, the land was cultivated without regard to the *nature* of the crops grown, and when it was thought that it required rest, the losing practice of *fallowing* was resorted to. But little importance was attached to the fact of one crop being more *exhausting* than another, or that it was good policy to succeed a crop which *left nothing* in the ground, by one that left its *roots*, to compensate in a measure for what it had taken from the soil. The rotation system was founded upon the utility of a change of crops for the benefit of the soil, and we hazard little when we say that it has been found as profitable in practice as it is philosophical in theory. In these remarks, we have no reference to the "excretory theory" of De Candolle, which, we think, is so far from being proved, that it is yet debateable.

Among other modern improvements (or so considered) now being attacked by certain writers, is that of *deep plowing*. This is one of the very last features of improved husbandry that we should have expected to see arraigned for faults. We had been convinced, from our own experience, and the concurrent testimony of observing farmers, that deep plowing was all that it ever had been recommended to be by its most zealous advocates an invaluable help to the farmer in improving the fertility of his soil, (of course increasing its products,) and saving expense for manure, or enabling him to apply it where more needed. We had convinced ourself—and the conviction is as firm as ever—that deep plowing and manure were the farmer's sheet anchor—his main reliances. We refer particularly to our Northern and Eastern farmers; —to those who till the prairie soil of the West, we have no reference.

To us it seems not a little surprising that this practice of deep plowing, which both here and on the other side of the Atlantic, has been considered, universally, so far as we are aware, as of the greatest advantage to the farmer, should now be decried by a writer, who, gifted beyond all others in the faculty of discernment, has discovered that it works the farmer no good.

However advantageous to our farmers may be the culture of roots or rotation of crops, we deem either of these of less importance than the improvement of *deep plowing*—and we are quite confident that he or they who shall attempt to write it into disrepute, will find that it has secured too fast a hold on the favor of our enlightened husbandmen, ever to be abandoned for the old "shallow" system, which (with all due reverence for the departed,) was indeed shallow in more respects than one.

From the Albany Cultivator.

CLEAN CULTURE.

It is a fact that ground which is kept from vegetation of any kind, will not dry up so much as that on which a crop is grown. There are many who doubt this, but if they would make a proper examination, their doubts will be removed. Make an experiment--take a piece of ground in the garden, and hoe it over every day, or often enough to keep all kinds of vegetation from starting. Sow another piece adjoining, with grass, or some kind of grain. After a drouth of two or three weeks, examine both pieces by digging into them with a spade or shovel. The earth of the grass or grain plat, will be found dry like ashes, to the depth perhaps of a foot or more. The other plat will be dried in only two or three inches--below that it will be found quite moist. Examine the ground in an orchard in a dry time, and if it is not naturally a wet piece of ground, it will be found dry to a great depth. If there is a tree in your corn field, see if the ground is not much dryer near it than on similar ground away from the reach of its roots. The fact is, the roots of vegetation bring up the moisture from a greater depth below the surface, than it could be done by simple evaporation. This may be known by noticing how much more moisture is required to support a crop of corn when the stalks are nearly full grown, than in its earliest stages.

Now, from all this we deduce an argument in favor of *clean culture*—that is, a culture which permits no useless vegetation to grow among cultivated crops; the advantage of which would be to give the crop the whole benefit of the moisture and other nutriment of the soil, instead of giving a portion to the worthless weeds.

In a dry time, we frequently hear farmers say, "it will not do to work my corn or potatoes, they need all the grass and weeds to keep the ground from drying up." Now this, as we have shown, is all a mistake; the grass and weeds make the ground dry faster and deeper. But it is alleged that corn has been injured by plowing or working it when the weather was very dry. We admit that this effect may have followed under particular circumstances: that is to say, if corn gets too large before it is worked, injury may be done. The reason is, that the roots have become extended, and the plow cuts off so large a portion of them, that the remainder cannot supply the stalk, and it soon withers. This is the way the "fired" corn, sometimes spoken of at the south and west, is generally produced. But it is only when the roots of corn have become widely extended, and are torn and mutilated in the operation of working it, that any such consequence follows. If the crop is worked, as it ought to be while it is small, no fears of injury need be entertained.

From the Southern Planter.

PHILOSOPHY OF WHEAT CULTURE.

Dr. Lee, who is one of the most devoted friends of agriculture in America, read a very able paper before a meeting at the State House in Albany, last winter, upon the cultivation of wheat. He calls to mind that from the analysis of Sprengel, the mineral proportion of the plant amounts only to three per cent. of the whole, and that wood ashes presents very nearly the same mineral constituents and in the same proportions; whence he infers, that soils the most wanting in these constituents, may be supplied with a sufficient quantity for all wheat bearing purposes by a small dressing of ashes. He goes on to say:

"Being but slowly decomposed by the vital action of plants, ashes are an enduring fertilizer when compared with stable manure. Mixed with quick lime, their good effects are more speedily obtained. Lime will render alumini either in the soil or in leached ashes, soluble in water, so that it can enter the minute pores of roots. Clay in the soil is always combined with a large portion of silica; and before it has been exhausted by continual cropping, it holds in combination considerable potash and soda.—Lime, by combining with alumini, the basis of clay, liberates these alkalies and silica, which, uniting chemically, form soluble silicates of potash and soda. These also enter into the circulating nourishment of plants, and are decomposed in the stems of grasses and cereals. The silica goes to make vegetable bone, to keep the plant upright; while the potash and soda go back to the earth, to dissolve, as before, another portion of sand, to be also absorbed, and transformed into bone. It is in this way that a few ashes, applied to a sandy soil, will enable grass and grain to take up the eighty-one per cent. of flint found in their ashes. Lime will do the same thing on clay soils, for the simple reason that they generally do not lack potash, soda and magnesia.

"The quantity of lime and ashes to be applied to an acre, will depend entirely on their cost at the place where they are to be used. A few bushels will be of essential service; but a larger dose will be better.

"I come now to speak of the organic elements of the wheat plant, which, as I have already intimated, form ninety-six or ninety-seven per cent. of its substance. Water and its constituents, oxygen and hydrogen, carbon and nitrogen, are the four elementary ingredients of all cultivated plants, beside their minerals. As there is no lack of water or of its elements, oxygen and hydrogen, our attention will be confined to obtaining a full supply of carbon and nitrogen. These are indispensable, and fortunately nature has provided an amount of carbon and nitrogen in the air, if not in the soil, more than equal to all the wants of vegetation. A large portion of the fertilizing elements of vegetable mould, in a rich soil, is carbon, and a small portion is nitrogen; both of which are usually combined with other substances. These important elements are often nearly exhausted in fields which have been unwisely cultivated; and I have paid much attention to the subject of cheap and practical renovation.

"By the aid of clover and buckwheat, dressed with gypsum, ashes, lime, or manure, and plowed in when in blossom, much can be done in the way of augmenting the rich vegetable mould so desirable, to a certain degree, in all soils. Straw, cornstalks, leaves of forest trees, and swamp muck, made into compost with lime and ashes, are of great value. Charcoal well pulverized, and saturated with urine, I regard as the cheapest and most useful fertilizer that can be applied to a poor soil, for the production of wheat or almost any other crop.

"The earths contained in charcoal, as the analysis of its ash demonstrates, are identical with the earths found in the wheat plant. Coal contains a very large portion of carbon, and will imbibe from the atmosphere a large quantity of nitrogen in the form of ammonia and its carbonates. Unlike stable manure, the salts of lime, potash, soda and magnesia, it will not

waste by premature solution nor by evaporation. On the contrary, it is of incalculable value to mix with the liquid and solid excretions of all animals, to absorb and fix in a tangible condition those volatile, fertilizing elements, which are so prone to escape beyond our reach.

"When it is recollected that without nitrogen in some form, it is utterly impossible to grow one kernel of good wheat, and that a pint of human urine or four quarts of that of the cow, or one quart of that of the horse fed on grain, contain nitrogen enough to supply sixty pounds of wheat, we may begin to understand something of the money value of this animal product. But mind this suggestion. Nothing is sooner lost than the hartshorn in an open smelling bottle, or a large share of the ammonia in free urine in a warm atmosphere. Charcoal and gypsum will absorb it in large quantities, and give it out at the roots of plants as their wants require. In feeding plants, great judgment should be exercised. At least one-half of the food fed out to them in the shape of stable and barn-yard manure, is entirely lost. It escapes into the air, or is dissolved prematurely, and carried like the potash in water running through a leach, beyond the reach of your hungry, if not starving plants.

"I have just separated a half pound of wheat flour into its proximate elements of starch and gluten. The gluten I have in my hand. It is nearly identical with animal muscle. It forms from seven to thirty-five per cent. of the bulk of wheat kernels. The more gluten flour contains, the more good bread a given number of pounds will make. A barrel of flour rich in gluten, will make ten per cent. more of bread than one which is nearly all starch. Gluten will bear far more water than starch. The quantity of this meat-forming principle in wheat, depends in a good degree on the quantity of nitrogen in the soil where the wheat is grown."

From the Maine Farmer.

TURNEPS AND TURNEP LIQUOR.

We do not know whether the common flat English turnep, as we call it, is any more nutritive in England than in America. We presume that there is no difference, and yet the farmers make great account of it in England, while here most of our farmers despise it. It has been asserted that the culture of turneps has more than doubled the stock in Great Britain.

It seems that men so shrewd, and so well able to calculate profit and loss as the English are, would not cultivate this root so largely if there were no profit in it. They can raise everything that we do, except Indian corn. Why, then, should there be so much difference in their and our mode of rearing and feeding stock? It may be answered, that their climate, being more moist than ours, enables them to raise turneps easier than we do; and their winters being milder, enable them to let their cattle run among the turneps and gather for themselves. We are willing to admit this, but at the same time remark, that all do not let their stock run out among them during the winter, but gather the turneps for the cattle; and some go so far as to cook them by steam, and find a profit in it.

We propose to give an abstract of a statement made by Col. Scobel, President of the Penwith Agricultural Society, on the subject of steaming turneps for his stock. He stated that he had tried this mode of feeding for twenty years, and that the more he tried it the more he was satisfied with it. He fed them, steamed, to his cattle, sheep, hogs and horses. His cattle amounted, for the last three years, to one hundred head, eighteen colts, seventeen horses, and about one hundred and twenty pigs. He stated that it did not require any more hands or help to steam and feed them out, than it did to feed without steaming. He said that he did not fatten his pigs on turneps, but asserted that he kept all his store pigs in good order by the drainage of his steam vat—that is, the liquor which was condensed and settled to the bottom. He did not steam the turneps over much, merely softening them. His theory is this: There is an acid in the raw turnep skin which physics the animal too much. By steaming, he extracted this, and softened the outside, which was much better than steaming them to a pulp. He also stated, that when thus cooked, they could be given to any extent in any weather, and that they would have the same effect as oil cake or hay and grain.

A Mr. James, who lives neighbor to Col. Scobel, said he had also followed the plan, and for five years had fed his horses and pigs on steamed turneps, and he was satisfied that there was nothing so good for feeding store pigs as the condensed liquor which was drained from the vats. It must be remembered that he cannot obtain Indian corn there at a price which will warrant its use. If he could, he would probably not have made such an assertion; but nevertheless, if the above statements are true, it is an object worth a trial even here, where Indian corn can be raised abundantly.

We give these statements to our readers, not because we know any thing in regard to the merits or demerits of the kind of food spoken of, but as agricultural news, and to let them know what the practice and views of farmers in other parts of the world are in regard to a root that is looked upon here, at the present day, with not very favorable eyes at least. Perhaps some of them may find themselves in a situation to give the plan a trial without much expense. If so, we hope they will do it, and let us know the results.

From the American Farmer.

THE SMUT IN WHEAT.

In looking over the Prices Currents in the chief wheat markets this summer, we have noticed unusual quantities of smutty wheat, and consequent reductions in the prices between such lots and sound wheat. The existence of this disease should not be permitted among farmers and wheat growers, as unfailing preventive means are wholly within the control of all. Unlike the rust, the smut may be prevented, by a very simple and unexpensive process. Such being the case, as the disease not only lessens the product to a very great extent, but depreciates the money value of the grain, and impairs the quality of the flour made from it, common prudence, and a becoming attention to one's interest, would seem to indicate, that every wheat grower should take the necessary precaution with his seed wheat, to prevent the unpleasant recurrence of the disease. All experience of wheat growers go to prove, beyond controversy, that smutty wheat, sown without preparation, will produce smutty wheat, whereas, when prepared, even that which had been previously blackened with the fungus, yields a grain entirely exempt from the parasitical enemy of the plant.

It is not our purpose now to enter into an examination of the various supposed causes which tend to produce the disease; for, at best, the opinions of the various writers must be supposed to be mere speculations, as there are scarcely any two who agree upon the subject. Nor shall we attempt to describe the appearance of the grain when affected by it, as all such information is unnecessary, the experience of every wheat grower having enabled him to anticipate us in that part of our information: it is, therefore, sufficient to the object we have in view, to point out a sure and effectual remedy, and at the same time to urge it upon all wheat growers to avail themselves of it the present fall.

The preventive means used, consist of various steeps, in which the seed wheat is to be immersed for 12 or 24 hours previous to being sown. These are—

1. A brine made of common salt.
2. A ley made of ashes.
3. A ley made of lime—and
4. Stale urine.

Each to be graduated to a strength that will float an egg or a potato. Salt is probably the best.

After the wheat shall have been thus soaked or steeped the requisite time, it should be drained through a basket or sieve, and dried either in lime or ashes, taking care to add a sufficient quantity of either to cover the grains well. While the seed wheat may be in the soak, it should be stirred two or three times well; the light or imperfect grains as they may float upon the surface to be skimmed off and fed to the stock.

The most perfect and effectual method of treating the seed wheat, would be, to wash it in pure water prior to putting it in the soak. By this process you make assurance doubly sure; though we do not consider it indispensably necessary, as the soaking and dusting will answer without it, unless, indeed, the grain be more smutty than usual.

It would be well to change the *soak*, after every parcel of wheat may have been soaked in it; and it is important that the grain, as taken out, and dried, or dusted in lime, or ashes, should be immediately sown and covered. It may remain for 48 hours in the soak without danger of impairing its vegetative properties, though there is peril of that effect being produced, should the grain be permitted to remain any considerable length of time unsown after having been taken out of the soak and powdered with either ashes or lime.

That the *smut* is an infectious disease, there is not the slightest room for doubt; for innumerable experiments prove the fact; but it is equally true, that it is controllable by a resort to the simple means we have pointed out. Then, why should it be permitted to exist and interfere with the interests of the farmer?

Besides the certainty of exempting the product from the disease, the soak operates beneficially, in promoting an earlier germination, and by urging forward the young wheat plants to form rootlets, thus entrenching themselves in the earth a sufficient depth, and defying the bad effects resulting from frosts and the alternations between the freezing and thawing points of the atmosphere.

We have before called the attention of our readers to this subject, and revert to it now, as the approaching seeding time seems to render the occasion a fit one to elicit attention.

From the American Agriculturist.

SUBSOIL PLOWING.

We are highly gratified to observe an increased attention to subsoil plowing, for we consider, if it could be generally introduced among us, it would be found one of the greatest agricultural improvements of the age. In vol. I, page 199, we gave full details of the successful operation of the subsoil plow in England, where it was shown, that by its use, crops may be doubled without adding a particle of fertilizing materials to the land. Two year's subsequent experience by the farmers of that country, corroborate the benefits to be derived by the free use of the subsoil plow, for grain as well as root crops. Mr. Tilley recently asserted before the Cornwall Agricultural Association, that he had the past year raised hundreds of roots of mangel wurtzel, weighing twenty-five pounds each; that the crop of these, per acre, as well as carrots and turneps, was at least doubled by subsoil plowing.

Five years ago, we had a piece of land containing two and a quarter acres of a hard clay soil, which, with the best management we could bestow upon it, yielded less than one hundred and fifty bushels of potatoes to the acre, and four hundred of sugar beet—while parsnips, carrots, or any long roots, it would scarcely grow. We had just heard of Mr. Smith's subsoil plow in Scotland, and determined upon an experiment. We had no plow of this description, nor could we then obtain one: we accordingly took the mould-board off from a large, strong road plow, and used the point of the share alone for subsoiling. We plowed the land in the fall of the year, by taking a common plow and one yoke of cattle, and turning over a surface furrow six inches deep. We then followed directly after this in the same furrow, with three yoke of cattle attached to the road-plow, stirring the soil eight inches deeper, making fourteen in all. This we then bountifully limed, and the

next spring as bountifully manured, and planted it with roots, and the following autumn obtained over one thousand one hundred bushels of sugar beet to the acre from it, and other crops in proportion.

Subsoil plows may now be had in this city, of excellent pattern and strongly constructed, from ten to fifteen dollars each, which will stir the earth from twelve to eighteen inches deep, requiring from two to five yoke of cattle to move them, according to the nature of the soil, and the depth required to plow.

From the American Agriculturist.

TOO MUCH LAND.

During a recent excursion in this, and some of the New England States, I was struck with the comparative sterility of land which might, by proper cultivation, become "the garden of the world." Instead of seeing fields of wheat bearing 30 bushels to the acre, we find that scarcely 12 to 15 is the yield: where two tons of hay should be cut, hardly one is the product; where thriving fruit-trees might be expected, bending beneath the weight of their delicious fruit, our eyes are pained by the sight of gnarled, stunted, and half-dead trees, scarcely able to sustain the life of the few curled-up leaves that come forth as if to reproach their owners by the sight of their consumptive appearance. If they had tongues to speak, how bitterly would they complain of their treatment. Is it because nature is so miserly, that she does not reward man for the labor he bestows on her, or because man will not let her yield a bountiful supply in reward for his labor? What is the cause of this sterility, and the complaints of the farmers that they cannot make a living, though they have hundreds of acres at their command? It is evident the fault is with themselves. They attempt the cultivation of *too much land!*

Our farmers have from 50 to 500 acres under what they call cultivation. Still they are in debt, and in many cases the more they possess the worse they are off. Their land is scattered far and near. Two acres here, and ten there, instead of being compact together. In this manner, more time is often lost in going from one lot to another, in building the fences of other people, and keeping out their cattle, than the whole income of the land amounts to. I have myself lost more time in this way in a single year, than it would take to keep ten acres in the finest condition.

What is the remedy? Sell half of your land and spend the proceeds of it on the remainder, and thus make what you have yield a liberal income. This may appear to those who have always "followed in the footsteps of their forefathers," of adding field to field to their farms, as the height of folly, but I am confident it will be their salvation. There is a good old adage, one that should be remembered by *farmers* as well as others—"Never attempt too much." Depend upon it, there is no course so suicidal as that of owning and attempting to cultivate 200 acres, when you can hardly do justice to 100. Suppose, for instance, a man has 50 acres of naturally good land, and he has but a certain amount of manure, time, &c., to use in its cultivation, which is not enough to keep it in heart, or pay that attention to rotation of crops, which it requires, is it not evident that the land, the owner, or whoever is connected with it, must suffer? Would not all intelligent persons condemn such a course? Yet how many such instances are to be seen all around us! I believe it would be for the interest of many farmers, even to give away a portion of their land, rather than have so much in their care. Self-interest tells us, it is the true policy of such a man to sell what he cannot properly use, for he would gain time to devote to the remainder, money to purchase all that it required, his crops would yield in double ratio, his land increase in value as it increased in fertility, and thus he would be in every way benefitted.

I have seen acres of the best land, overrun with daisies, mulleins, and other noxious plants, that root out the grass, and eat up the life of the soil, without affording nourishment to man or beast, which might by a little attention yield a rich harvest. But the farmer has no time to attend to it, and the land becomes worse than useless; for it is self-evident that land must either increase in fertility, or decrease in value; there is no middle way—it must afford a profit or be an expense.

Look again at the swamp and meadow lands, with which our country abounds, that are now worthless, and causing sickness and death in their vicinity. All these might be reclaimed and made the most productive land, by a small outlay of time and capital; the owners have neither, because they have too much land already calling for their attention. The muck contained in these places, can be made to pay better interest than bank stock; yea, if properly used, it may be the farmer's mine of wealth.

This leads me to inquire how are our lands rightly to be cultivated? I reply, by using the experience and directions of those who have studied the chemical formation of soils, and the effect different manures have on different soils. Much time is lost, and land injured, by the farmer not knowing the relative value of his manure, and the theory of rotation of crops, which might be saved by the expenditure of a little time and money in procuring and reading agricultural papers and books. There is too much of the saving a cent, and losing a dollar economy in this age. When the time shall have arrived that men will be willing to study the theory and practice of farming in all its details, then shall we see agricultural pursuits elevated to a proper standing and yielding a profit that shall rejoice the hearts of all. C. Casse.

Orange County, New York.

From the Plow Boy.

AGRICULTURAL PURSUITS.

So wide is the field of the farmer's labor, and so many the objects connected with his various employments, that we see no reason, having aught of sound argument, why the farmer should not be the most learned of men. They have more to do with the element of nature than others, and are practical chemists, depending upon the earth for subsistence; they, by time, separate, modify, and change the simple and compounds, so as to afford the several elements of which the vegetable kingdom is composed, thus making of the farm a workshop and laboratory. In plowing and preparing his land for seeding, he is a practical mineralogist and geologist; in observing and preventing the ravages of destructive insects, he is a practical entomologist. Indeed, to enumerate his various employments would be hardly possible. He is the practical botanist and meteorologist; but it is quite improbable that one man should be perfect in all these branches: yet the farmer, by a more attentive examination into the cause and effect of all which occurs under his immediate observation, may become a better natural philosopher than heretofore, and, by the cultivation of his mental powers, command and retain that respect to which he is so justly entitled, as one of the producers of the wealth of the nation, and as one of the many pillars of the constitution. Of all the various employments which have from time immemorial engaged the attention of men, none have been so pre-eminently useful, more honorable, nor so nearly connected with our interest as nations, as individuals, than agriculture; its pursuits offer to the ingenious mind more opportunities for research and experiment than any other science, yet it is a lamentable fact, that there exists among the farmers an apathy to the pursuits of knowledge, and a want of that spirit of inquiry respecting the nature and habits of those objects upon the perfected cultivation of which depends the production of real wealth. What is the cause of this? A want of the proper estimation of the pursuit of agriculture. Is the cultivation of the soil regarded with contempt? 'Tis an abused idea, and we believe it too generally prevails, else why are so many of our young men engaging in the professions, too full, long ere this, for the country's good? and why are so many ensconced behind the counter, to learn the art and mystery of measuring a piece of tape? and why are the many mechanical branches so completely overstocked, while agriculture, the main support of the nation, holds out so many inducements for its pursuit, at once more interesting, more profitable, and, as improvements are made, less laborious than either the professions, the mechanical, or mercantile pursuits?

Agricultural pursuits may be made profitable; and the farmer's profits are sure, while, by the fluctuations of the market, the merchant or manufacturer may be robbed of the reward of their labor. They may have done everything which intelligence and industry could to insure success, and yet, at the year's end, wind up business with a loss, not only of profits, but capital too: but this cannot happen to the industrious farmer; his capital is invested in the soil, and he draws upon a fund which has never failed, since time immemorial, to honor all just demands: his profits may be diminished, but never wholly suspended. Although they are more imposed on than any other class of the community, and have less money, still they may grow rich. The mechanic may earn his six, eight, or twelve dollars a week, yet his condition is no better at the year's end than when he commenced it; while the farmer, earning from fifty cents to one dollar a day, grows rich. If the artizan lays down his tools, and the professional man is idle, they are sinking money: not so with the farmer; if he sleeps, his wealth still accumulates. Indeed, the mechanic, physician, merchant and idler, may receive their thousands yearly, yet die poor; while the farmer scarcely receives as many tens, and lives and dies as the lord of the soil. Many deem farming fit employment for such only as have not sense enough to pursue anything else; notwithstanding the glaring facts, that from the soil is drawn nearly all the wealth of the nation.

From the Boston Cultivator.

RECLAIMING EXHAUSTED LANDS.

Messrs. Editors—I present you with the following experiment in reclaiming worn out lands, which will be read with interest; for the mode adopted is so judicious and rational, that such a course of procedure must of necessity prove decidedly advantageous under any circumstances. I have no doubt the plan of mixing lime with earth before using, would be found of far greater importance in the application of that article to land than any other mode; allow me, therefore, to call the attention of your readers to the circumstance of the compost acquiring, by frequent turning, "the appearance and smell of soaper's ashes," and proceed to give, in the words of the writer, the following interesting statement. S. Marshall.

I will inform you the Rockland Farm exhibited a subject for experiment, as it has been reduced by cropping. Having read in various books the result of sowing plaster and clover, it was presumed that the sowing of these would be the extent of the expenses required to fertilize the fields in a few years; but the experiment proved that the plaster and clover used were both lost, as no one could point out, at any season of the year, what field they had been deposited upon. The soil was a cold or heavy clay, blue, white, light, brown, and a few spots of red clay, loaded with hard blue stone and rocks, chiefly quartz, mixed with iron and copper. Some of the experiments were made with plaster; others were made by top-dressing with lime, at the rate of 25 to 30 bushels per acre; the lime being brought 25 miles from the kiln, and laid on the land at 25 cents per bushel. It was formed into a bed, six inches in thickness, and covered with earth that had been plowed and thrown over it before it was slaked; a heavy harrow was passed over it as soon as it had been reduced to powder, and the bed of lime and earth was then *frequently turned* by the plow and harrow, until the whole assumed the appearance and smell of soaper's ashes, containing about ten parts of common soil to one of lime. It was then carted

and spread regularly over the field; and in every instance it gave a return of clover, equal to ten loads of stable manure to the acre. The idea of mixing the lime and earth, was suggested from spreading the refuse of lime and sand gathered from about buildings, and laid upon the fields, the effect of which I observed, was more immediate than any equal quantity of clean lime, although the mixture of lime and earth was equally so; the succeeding rains carrying the fertilizing principle of the lime, as from a sieve, into the soil below, completely dividing it, and rendering that which was before too compact and cold for the roots of the grass and grain to live in, both warm and open—when immediately the whole soil, which before felt hard under the foot, became so elastic that persons of observation, by walking over the field even in the night, distinctly told how far the lime and earth compost extended: the color of the soil was likewise changed into that of chocolate: now these effects seemed to prove that anything which would separate the particles of the soil and admit the air, would render these cold and heavy clays warm and fertile, the free intercourse of air carrying off the acid, &c.; and to meet this idea, plowing in the fall was adopted and found successful. As an experiment, one half a field, six years ago, was plowed in the autumn, the other half in the spring; but that part which was plowed in the spring, has never yet brought grain or grass equal to the other. Spreading manure in the autumn from the compost heap, has also been attended with universal success, both upon grain and grass; the salts of the manure being carried into the soil by the rains upon the breaking up of frost, which had in some measure prepared the soil to receive it. Vegetable substances have also been covered with earth, and when well rotted, the compost has been used with the same success as stable manure; and so long as they operate in separating the soil and promoting the access of the air, they fertilize and change the color of the mould. W. Young.

SOUTH CAROLINA STATE AGRICULTURAL SOCIETY.

In consonance with a resolution passed at the last meeting of the South Carolina State Agricultural Society, the following premiums are offered for stock, at the exhibition to be held in Greenville, on the 2d Wednesday in September next.

For the best Stallion over 5 years old, for Harness purposes, a Silver Cup,	$15 00
For the best Stallion over 5 years old, for Saddle purposes, a Silver Cup,	15 00
For the best Stallion or Colt, under 5 years old, a Silver Cup,	10 00
For the best Mare or Filly, under 5 y'rs old, a Silver Cup,	10 00
For the best Mule, over 3 years old, bred by a member, a Silver Cup,	10 00
For the best Mule, under 3 years old, bred by a member, a Silver Cup,	10 00
For the best Bull, over 1 year old, a Silver Cup,	15 00
For the best Bull, under 1 year old, a Silver Cup,	10 00
For the best Milch Cow, a Silver Cup,	15 00
For the best Heifer, under 1 year old, a Silver Cup,	10 00
For the best Boar, over 1 year old, a Silver Cup,	10 00
For the best Boar, under 1 year old, a Silver Cup,	5 00
For the best Sow, over 1 year old, a Silver Cup,	10 00
For the best Sow, under 1 year old, a Silver Cup,	5 00
For the best Ram, a Silver Cup,	5 00
For the best Ewe, a Silver Cup,	5 00

The local Societies are requested to appoint Delegates to the meeting at Greenville, on the 10th of September, and a general attendance of the members is most earnestly requested.

The papers friendly to the Society are requested to publish the above till the meeting.

W. B. SEABROOK, President.
J. B. Davis, Secretary.

COMPARATIVE VALUE OF ARTICLES USED AS FOOD.

Professor Silliman has given a translation of M. Dombasle's experiments with several articles in feeding animals. Seven lots of seven sheep each were selected, of nearly equal weight, kept in separate divisions of the stable, the weight of each lot ascertained once a week, and the experiment continued five weeks. One of the lots was fed exclusively on lucerne hay, of which each sheep was found to eat 15 pounds per week. Each of the other lots received half the quantity of lucerne, and enough of other kinds of food named to keep them in good health, and of the same weight. The kinds of food used were, dry lucerne, oil cake, oats and barley, raw potatoes, cooked potatoes, beets and carrots: of these substances, the quantity found necessary to equal the half ration of 7½ pounds of lucerne, withheld from all the lots except the first, was as follows:

Oil cake,	4½ lbs.
Barley,	3½ "
Oats,	3 "
Raw potatoes,	14 "
Cooked potatoes,	13 "
Beets,	16 "
Carrots,	26 "

or in other words, 23 pounds of carrots were only equal to 7½ pounds of lucerne hay, 4 pounds of oil cake, or 3 pounds of oats. It may be remarked that the quantity of water drank by each lot of sheep was also accurately ascertained, and while those fed on grain and oil cake used during the experiment about 200 quarts of water to each lot, those fed on roots did not use 100 quarts; and those on carrots, only 36 quarts.

PRODUCTS OF NATIONAL INDUSTRY.

Professor Tucker, of Virginia, estimates the products of our national industry as follows:

Agriculture,	$654,387,597
Manufactures,	239,836,224
Commerce,	79,721,087
Mining,	42,358,761

MAPLE SUGAR.

It cannot be generally known that the great increase in the manufacture of this article is driving West India sugar out of the market: we have been informed that 10,000 hogsheads of maple sugar are sold annually in this city. There is scarcely a farmer in the interior of this State who has not a grove of maple trees from which he makes all the sugar he requires for family use. By mixing a little hot water in the syrup, it makes capital molasses. Great improvement is making in bleaching and granulating maple sugar, and by chemical process depriving it of its woody taste. In time, no other sugar will be used in this country, (excepting, perhaps, cornstalk,) and we can make it in any quantity and at a trifling cost.

To preserve Hams or other smoked meat through the summer.—Wrap up the meat in tow, of either flax or hemp, after shaking out the loose shives, and pack it in a barrel, taking care that there be next the barrel and between the meat a thick layer of tow, packed in as close as possible; then set it away in a dry cellar or upper room. It is enough that the barrel be sufficient to keep the mice out, as no fly or insect will enter the tow.—*Ag. Almanac.*

Arkansas Insects.—The last Arkansas Traveller tells a good story of a citizen of that State who, while on board a steamer on the Mississippi, was asked by a gentleman "whether the raising of stock in Arkansas was attended by much difficulty or expense?"

"Oh yes, stranger—they suffer much from *insects*."

"*Insects!* Why, what kind of insects, pray?"

"Why---*bears, catamounts, wolves*, and sich like insects."

The stranger stopped further inquiry, nor did he deem it necessary to explain to the Arkansas man some passages in Goldsmith's Natural History.

Distraining for Rent.—"Speaking of Turkey," a man up town, on going to dinner a day or two ago, found a magnificent turkey, smoking hot on the table.

"Ben," said he to the boy waiting upon him, "where the devil did this turkey come from?"

"Why, sa," replied Ben. "dat ar turkey is been roostin on our fence dis two night, an dis mornin, I *seize him for de rent ob de fence!*"

A great nigger that! We have a shrewd suspicion that he understands the laws of Turkey much better than his master.—*Pic.*

Paralysis.—A correspondent of the Boston Mercantile Journal communicates to that paper the following extraordinary cure of a case of paralysis. Can there be anything in the mode of *treatment* pursued?

A few weeks since, a gentleman in Salem was seized with paralysis of the left arm, and to use his own words, "it seemed as if a sword had been thrust through his arm from the shoulder to the fingers, and it instantly fell powerless at his side." He hastened to his physician, and he pronounced it a plainly marked case of palsy. He in some degree recovered the use of the same, but it still remaining in a bad state, in company with a friend he went to Ipswich for recreation and exercise, hoping to receive benefit from the same; after strolling about upon the sea shore, and becoming much fatigued, he found a resting place upon the sandy beach. During his siesta, his hand became imbedded in the sand: very shortly a violent prickling and twitching sensation commenced. Receiving encouragement from this unexpected return of action in the part, he excavated a place in which he placed his arm, and covering it up, soon fell into a quiet sleep, and so remained about an hour. On arising he found to his surprise and delight, that he had entirely recovered the use of this arm, and he still has perfect use of the same.

A Yankee Wager.—The cool and collected manner in which a Yankee will come the 'cute,' says the Flushing Journal, over his more obtuse neighbor of a few degrees Southward of "down East," was exemplified in an incident which came under our observation a day or two since. A jovial, good natured and tall harum-scarum dealer in wooden bowls, who has been peregrinating our neighborhood with a wagon load of the article, and by his off-hand and dexterous management, has supplied almost every other house with his ware, stopped at the Flushing Hotel, and was accosting its guests to purchase, and expressing himself willing to effect a bargain on almost any terms, by regular sale, barter, or by wagering on "politics, religion, or any thing else;" hurrahing for Henry Clay, &c., and finally offering to bet that the great Kentuckian would obtain the electoral vote of his own state—Maine.

Mine host of the hotel, who has implicit faith in Polk and Dallas, to stop the mouth of the bowl vender, offered to bet six of the best wooden bowls, at fifty cents each, Clay would not get the vote of Maine; which was immediately accepted by the shrewd Yankee, who insisted that the contract should be reduced to writing; which on being done, it was agreed that the bowls should be deposited in the hands of some third person until the election contest was decided. But when our Yankee asked our friend Hover where were *his* six bowls to put along with them, it appeared as though the ribs of the spectators would have split asunder by their uproarious laughter. Our friend of the hotel offered to purchase them at the stores; but when we came away, the Yankee was driving a bargain with mine host to supply him on much cheaper terms than they could be procured of the store-keepers. It can be easily imagined how the affair ended, viz; that the Yankee sold his opponent six bowls, leaving other particulars out of the question.

The advice of a wise man is to be considered as a prediction.

DURABILITY OF SALT AS A FERTILIZER.

Some four years ago, we applied six barrels of (spoiled) salt fish to a strip of potatoes in a field of four acres, in comparison with yard manure. To every hill, we put half a herring or mackerel, at the time of planting. The season proved a very dry one, and while the vines in the other parts of the field suffered greatly from the drought, those where the salt fish was used, maintained a dark, vigorous and healthy color, vines very large, long, and continued green some time after the others were shriveled, dried and dead. On raising, we found them much larger in size, and nearly double in quantity, to those where the yard manure was applied.

At the time, we attributed the great yield over the others, to the animal substance, as nothing but the bones of the fish were found in the fall, but on further reflection and observation, we are inclined to think that the salt was the most powerful agent after all, as will appear from the crops taken off the three following years.

The next crop we took from the same field was Ruta Bagas, and that part where the fish was used, showed a much more vigorous growth of plants, maintained the same dark, healthy appearance, and could be distinguished from the rest at a great distance, but on lifting them in the fall, we found that the great growth of top was at the expense of the bottom; the bulbs were smaller than those in the other part of the field; thus for Ruta Bagas, it proved rather injurious.

Last year the field was sown with oats, and produced a very heavy crop. The strip where the salt fish were used, was visible to the eye, at a great distance from the field, and the straw much larger and longer; but just before the heads filled out, a severe storm of wind and rain prostrated it; before which it was the most vigorous growth of oats we ever beheld.

After the oats were taken off, we had it plowed deep, the stubble well turned under, harrowed and rolled until well pulverized, and then sowed with wheat, and stocked down with clover and timothy. The plants soon made their appearance, and grew off vigorously in the fall, but owing to the small quantity of snow, and the severity of the frost in the winter, much of the grain was killed, which gives it rather an unsightly appearance, and looks a little patchy.

On passing the field a few days since, my attention was arrested by the vigorous growth, dark color, and the heads presenting in full bloom, were much taller, better tillered in that part of the field where the fish had been applied, while on the other parts, the heads of the wheat just began to present themselves. The lines where the fish was used, could be traced by the eye at a great distance.

The question now presents itself—which is it that has been such a lasting and powerful agent in producing such extraordinary fertility? Is it the flesh, the bones, the salt, or all combined? The animal matter disappeared the first season, and nothing but the bones were to be seen, and the quantity of salt was so small, that it would seem hardly possible that it would have such an effect. Salt as a manure for grass lands, meadows, &c., has been used in all parts of England, with varying success. It is said to sweeten the herbage, and when sprinkled about, and over a portion of pasture, cattle, sheep and horses, will constantly repair to this salted portion, in preference to any other part of the field. It evidently, therefore, rendered grass more palatable to live stock, and upon consulting the old agricultural writers, it was found that the notices of salt as a manure, were many and important, and that it had been used in various agricultural operations, from a very early period.

Salt renders the earth capable of absorbing the moisture of the atmosphere, "a property of the first importance, since those soils which absorb the greatest proportion of moisture from the atmosphere, are always the most valuable to the cultivator."—*Ag. Chem.*

Its fertilizing properties, when applied to land, may be described as five in number.

1st. In small proportions, it promotes the decomposition of animal and vegetable substances. Salt, therefore, promotes the rapid dissolution of animal and vegetable remains, contained in all vegetable soils.

2d. It destroys vermin, and kills seeds, which are thus converted into manure.

3d. It is a direct constituent, or food of some plants; and it has been clearly ascertained, that if salt is applied to a soil, the vegetables afterwards growing on that land, are found to contain an increased proportion of common salt.

4th. Salt acts on vegetable substances as a stimulant. And

5th. Salt preserves vegetables from injury, by sudden transitions in the temperature of the atmosphere. That soils do not freeze so readily as usual, when salt is applied to them, is well known; and that salt preserves crops of turneps, cabbages, &c., from injury by the frost, is equally well estal lished.—*Johnson.* B.

From the Maine Farmer

THE WAY FRIEND HANSON MURDERS TWITCH GRASS.

We examined a field of corn the other day, belonging to our neighbor, Moses Hanson, which had formerly been covered with twitch grass, or as some call it, couch grass, one of the worst pests, as every person knows, that could torment a farmer. The *dry bones*, alias *roots* of the plant, were lying in great plenty in every direction, but thoroughly dead, while the corn was growing in great luxuriance upon their remains. If we mistake not, the following is the history of its management. A year ago last spring, he turned the sod over flat. He then carted on his manure and spread it. He then took his horse, and with a small plow turned the manure, but not so deep as to disturb the sod. He then harrowed it, and planted the long red potato which was hoed as usual. The potatoes soon covered the ground, and so shaded what was left of the grass that it could grow but very little. After the potatoes were dug, he took his plow and team and turned the sod, which had now become partially rolled up on its edge, leaving it so during the winter to receive the close embraces of Jack Frost, and he did hug it tight last winter, "that's a fact."

In the spring, he run the harrow over it and planted his corn—manuring it in the hill. This has been hoed twice, and there isn't twitch grass enough left alive to feed a hog with.

From the Maine Farmer.

SPIRIT FOR CHILLED LAMBS.

Mr. Holmes—Although the usual season for lambs this year is passed, yet I should hope the following would be remembered against another season. If sheep lamb after the middle of April, as they should do, they are liable to lamb in the night, or in a cold storm, and the lambs become chilled with the cold, and die in consequence. A friend of mine mentioned to me that he had heard it said that spirit (rum) was the best thing to be given—made suitably weak by water, and sweetened with molasses; and that this year he had one opportunity to try it, and it succeeded to his most sanguine expectation. Every thing that will benefit the rearing of sheep and production of wool, appears important to me, and, as I think, is important to the State. Elijah Wood.

Winthrop, August, 1844.

BLACKBERRY SYRUP.

This is said to be almost a specific for the summer complaint. In 1832, it was successful in more than one case of cholera. To 2 quarts of juice of blackberries, add

1 lb. loaf sugar,

½ oz. nutmegs, ½ oz. cinnamon, pulverized,

½ oz. cloves, ¼ oz. allspice, pulverized.

Boil all together for a short time, and when cold, add a pint of fourth proof brandy.

From a tea spoon full to a wine glass, according to the age of the patient, till relieved, is to be given at a dose.

☞The man who makes his potato-ground feed flowers, prevents its feeding his children.

From the Maine Farmer.

"I came to the place of my birth and said, "The friends of my youth, where are they?" And echo answered, "Where are they?"

BY JOHN S. LYNDE.

I journeyed on to sunset skies,
Was eager to be there,
To gaze on scenes with longing eyes,
That once were dear and fair.

'Twas when the moon was soaring high,
In clear and starlight heaven,
The whippoorwill soft warbling nigh
The mournful song of even,

That here I sat me down alone,
Beneath my childhood tree,
And called to mind those days far gone,
Those days no more to be.

I dwelt on hours long flown away,
Old scenes to memory come,
I thought of all so bright and gay,
That blest my early home.

The rocks and trees beside the stream,
That youthful band so dear,
Their music came all like some dream,
Lost notes on memory's ear.

'Twas here we met in school-boy play,
When sunshine lovely smiled,
Beneath the trees all green and gay,
I played a joyous child.

The grove that stood beside the spring,
Long years had hid from me,
The trees were fell, and every thing
Had passed time's surging sea.

O'er that fair field where once I toiled,
Green waving branches hung,
The garden old had grown a wild,
In which the blackbird sung.

The clear bright spring that filled the cup,
When boys were let from school,
Had ceased to boil and sparkle up,
Was but a stagnant pool.

The old round rock on which I played,
And drank the mountain gale,
Was rolled away, and downward strayed,
Laid low within the vale.

And that old house and home I left,
When life was young and gay,
Of inmates all, was now bereft,
For each had gone his way.

In that dear cot my mother sung,
Her cradle songs of yore,
The swallows lived—and round it hung
The insects on the flower.

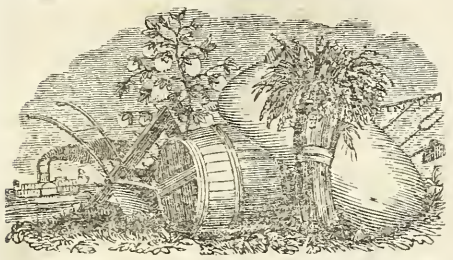
The friends I loved, the things I knew,
Had vanished most away,
And all the strange remaining few,
Wore locks of silver grey.

'Twas then I dreamed of friends of yore,
Their cold and mossy graves,
Bright scenes of youth, deep darken'd o'er
By time's devouring waves.

All things had changed, most friends had fled
Like fading hues of day;
A voice came up from death's dark bed,
And echoed, "where are they?"

August 4, 1844.

Soap-suds to kill Plant Lice.---Mr. Thos. Sinclair, of Brighton, tells us he has been using whale oil scap to kill the lice on his fruit trees. He uses but two pounds of soap with 14 gallons of water, and he finds it fatal to the lice on the leaves and tender twigs. He applies the suds by means of a syringe, and he says it makes the leaves look more thrifty than before.—*Mass. Plowman.*



WEDNESDAY, SEPTEMBER 4, 1844.

☞Numerous complaints have been made by the Farmers in Putnam county, and other places, during the past month, that gypsum (plaster of Paris) no longer acted beneficially upon their land. The reason of this is thus explained by Leibig:—"When we increase the crop of grass in a meadow by means of gypsum, we remove a greater quantity of potash with the hay than can, under the same circumstances, be restored—hence it happens, that after the lapse of several years, the crops of grass on the meadows manured with gypsum diminish, owing to the deficiency of potash." From this extract, it will be seen that nothing is wanted but the application of ashes or potash to the land, when plaster will again act upon it with its former good effects. Plaster will also be found beneficial again after manures have been used for a few years, more especially when made of an intermixture of swamp-muck or peat-earth.

☞It is stated, in the Albany Cultivator, that Ireland contains about 15,000,000 of acres of land under cultivation—only 4,000,000 more than the State of New York; yet Ireland, with a population of about 10,000,000, exports annually more grain than the whole territory of the United States. From government surveys lately made in Ireland, it is stated there is yet remaining five millions of acres, unimproved, capable of profitable cultivation.

It is also stated there are 15,000,000 of acres of a similar character in England and Scotland; so that it cannot be supposed that those countries, notwithstanding the vast advances they have lately made in agricultural improvement, are as yet anywhere near the highest limit of production.

WOOL.

We see it stated in the Tennessee Agriculturist, that Messrs. Buger & Chappell, of New Orleans, advertise for $1,000,000 lbs. of Wool, which is destined for the French market. This will open a new era in the agricultural business of some parts of our country, ad pted to wool growing, as it is said the demand for the new market thus opened will be permanent and increasing.

It has been thought heretofore, pretty generally, that a cold climate was necessary for the production of fine wool, but it would seem that this conclusion does not rest on a good foundation. Some specimens purchased by the above house, at Nashville, Tenn., have been pronounced by the agent the finest samples of wool he had ever seen in this or any other country.

☞Rheumatism having once seriously attacked sheep, the malady will seldom be completely eradicated—so kill the disease at once. There are a thousand proofs (says the Nashville Agriculturist) of the existence of this complaint in sheep. It is particularly prevalent in low marshy countries, in exposed situations. It principally attacks old sheep and young ones. It sometimes appears as an inflammatory complaint, and fever accompanies it; and at other times it has all the characteristics of a chronic disease, the walk of the sheep or lambs being stiff and cautious, marking the rheumatic patient.

☞An exchange paper very truly says, sensible men and women never sneer at mechanics and others who earn their living by their labor. But self-styled gentlemen and ladies not unfrequently do. We have heard of a "lady" who once left a ball-room because a mechanic entered. She married a basket-maker, and died a washerwoman.

☞The best kind of field-bean is of small size, plump, round, and slightly oblong in shape, and of a white color. It is common in the Eastern States, and one of the finest samples of it is now being distributed over the country by that indefatigable friend of agriculture, the Hon. H. L. Ellsworth, Commissioner of the Patent Office.

LUCERNE.

In no former period (says a correspondent of the Mark-Lane Express,) have I experienced the value of lucerne, as during the present protracted drought. I have now nearly finished my first crop, which I have been cutting green for horses and cows, much of which measures in height 36 inches, and very thick. My second crop is now from 24 to 26 inches high, and as thick as the first. I am now about cutting this for hay. It does not appear to be in the least affected by the severe drought, which I attribute to the very great depth the roots run down. I would again urge all farmers to try to grow lucerne; for of all summer food for horses, this is the very best. I am inclined to say, likewise, nothing can be better food for cows, for my own have lived entirely upon it the last three weeks, my feeding pasture being quite burned up for want of rain, and have produced a full quantity of butter.

SALT AND SOOT.

The effect of salt, (says the Boston Cultivator,) when combined with soot, is extraordinary. The Rev. E. Cartwright found, that in one row manured with this mixture, he obtained two hundred and forty potatoes; while in an adjoining row of the same length, treated with lime, the yield was only one hundred and fifty.

☞It is stated that the ship Orpheus, at Baltimore, from Chili and Peru, brought 400 tons of guano. A few more such importations will reduce the price of the article materially.

☞George Bancroft, Esq., the historian of the United States, is to deliver the annual address before the New York State Agricultural Society.

Value of Toads.—A person lately opened a toad in a wheat field, and found sixteen beetles in its stomach, which the patient animal had probably snapped up while they attempted to cross the path.

From the American Farmer.

TABLE OF SOILS.

Thaer, a very eminent agricultural writer, one who is of received authority, thus classifies various soils and their adaptations to the several crops enumerated—from which persons who may be improving their lands may judge of the quantities of manures, vegetable, animal and mineral, necessary to be applied, having first ascertained, by analysis, the constituent elements of which their lands to be improved consist of.

Systematic Names	*Usual Name.*	Clay, p ct.	Sand, p ct.	Humous pr. ct.	Lime, p ct.

Average small quantity of lime

COCKLE BURR.

We gave in our first number a fact, (says the Mississippi Farmer,) communicated to us by James Quesenberry, one of our subscribers, respecting the poisonous effects of this weed upon hogs. The editor of the Southwestern Farmer gives an instance of a friend of his who lost his entire stock of hogs by eating the cockle-burr. J. A. Hamilton, a correspondent of that paper, gives the following case, which is entitled to the highest credit, and it confirms the opinion of our correspondent, Mr. Quesenberry, that the cockle-burr is poison, at the time it is swelling and sprouting to grow, although at other times it may be harmless.

"We have had a similar disease among hogs in this neighborhood to that in Hinds. I have heard several complain of losing their hogs; but none can give the cause of their death. I have been more unfortunate with Mr. Affleck's hogs this season than I ever was with hogs before, but cannot attribute it either to cotton seed or peas, for they had not access to either. When I came here in November, the hogs were running in a sweet potato field, and corn field adjoining it; were fine and fat: when the potatoes were gone, I turned the hogs into a different field, which was intended for their pasture, and had been let grow up in cockle burrs last year, and fed them bountifully with corn. They seemed to do well until the burrs began to come up, when they commenced dying, in fine order. Having heard, from some source or other,—I do not recollect where—that young burrs would kill hogs, I turned them into another field that had no burrs in it, and fed them on boiled cotton seed, and, to my satisfaction, I lost no more hogs until I turned them again into the burr-field: after they had been there about a week, they commenced to die again. I then turned them into a field of green oats, where they have been ever since, without losing any more of them. From this trial, I am induced to believe that young cockle-burrs will kill hogs."

Drink for Haying.—Let farmers who are now hard at work haying, have for drink, milk porridge with corn meal in it. This keeps off fever in the stomach, and is better for allaying a feverish thirst than almost any other beverage.

MARLING IN SOUTH CAROLINA.

That there has been, within the last two years, a greatly increased and growing interest in the subject of agriculture, excited among Southern planters generally, is apparent to the most casual observer; and that its march will continue to be onward, diffusing its benefits upon all classes, needs not the spirit of prophecy to foretell. Evidences are not wanting to attest the truth of this remark—they are to be found in the formation of numerous Agricultural Societies throughout the entire South, and particularly in the old States, for the diffusion of knowledge, and the excitement of a generous and laudable rivalry among our people; in the greatly increased attention which is everywhere bestowed on the subject of manuring: and last, though not least, in the desire everywhere manifested for the diffusion of information by means of agricultural papers and periodicals.

These are the proofs, and they are not only abundant, but daily increasing—and they give earnest of a brighter and more glorious era, in the progress of this important science, than has ever dawned upon the sunny South—an era which will be distinguished for the diffusion of its countless blessings and unparalleled prosperity among all classes of our people. We rejoice, heartily rejoice, at the flattering prospects which the contemplation of this subject discloses to our view. We see in it the evidences of a strong and abiding attachment to the hearths and firesides of our youth, and the homesteads of our fathers—the indulgence of which noble feeling, while it will arrest the tide of emigration that has for so many years been going on, depopulating the old States, and transferring many of their most valuable and enterprising citizens to the regions of the far west, will prompt to the beautifying, adorning, and enriching those spots endeared to us by so many thrilling associations. Such will be as certainly the result of that spirit now exhibiting itself among our planters, as that effect follows cause; and the day is not far distant, when the States of South Carolina and Georgia will boast a more intelligent, enlightened, contented and prosperous people, than has ever tilled their soils even in their virgin purity and richness.

The march of South Carolina to this high destiny is onward and rapid. She has seen and felt the deleterious influence of a system of agriculture which has laid waste her lands and depopulated the State, and her Legislatures, like wise men and patriots, have stepped into the breach to arrest the downward tendency of things; and in that spirit which became a prudent and enlightened people, have ordered a survey of the State by a competent and scientific agriculturist, which is already beginning to discover the advantages that must ere long result from such a policy. That the prospect now augurs the most happy and beneficial influences upon her agriculture and the prosperity of her people is evident, and we beg leave to introduce the following extract of a recent letter from one of her most intelligent planters, to the Editor, and also the subjoined article from the Cheraw Gazette:

"Since the publication of Mr. Ruffin's report of the "Agricultural survey," much attention has been given to the subject of marling. Marl pits have been opened on many plantations, and experiments are in progress in the hands of educated and scientific men, which must improve the spirit and enterprise of our agriculturists, and be highly favorable to the circulation of a good Agricultural paper. A great many important facts, the results of careful experiments, should be, and will be reported."

MARLING.—We are much rejoiced to learn, that many estimable citizens on the Pee Dee, have at length been convinced, by practical experiments, of the highly beneficial effects of Marling, on our exhausted and worn out lands.

We have been recently favored with the perusal of a letter, written by an intelligent, practical planter, who has become an enthusiast in the system of marling, detailing experiments made by himself, which show so clearly its astonishing fructifying qualities, that none will hereafter doubt, who are not determined to reject all proof, and remain in stubborn and wilful ignorance and disbelief.

The writer of this letter, Mr. James F. Belin, says, that he thinks the land he has marled, on which he has planted both cotton and corn, will yield him a profit, at the very lowest calculation, of *one hundred and fifty per cent. the present year!* A portion of this land was "old fields," which he supposes have been tended for over one hundred years. He says he has fifty-five acres of cotton on a part of this land, which, from present appearances, will yield between forty and forty-five bales, of 400 lbs. each. The same land, *without marling*, would not produce over eighteen or twenty bales at the outside, as has been proved by subsequent planting. In 1842, the land here spoken of was planted in cotton, without marling, and the weed did not grow above knee high; now it is in many places as high as a man's shoulders, and remarkably full of bolls—many acres, he thinks, will come very near averaging a bale to the acre.

Mr. Belin has also, the present season, 25 acres of cotton, *not marled*, from which he does not expect to gather more than ten bales, and this from a piece of fresh land, it being only four years under cultivation. This would have been considered a piece of tolerably good cotton, but it will, he says, bear no comparison with that growing on his "old fields."

The effect of marl on corn is equally surprising and satisfactory. He has planted corn on marled land, which he is convinced will yield 14 or 15 bushels to the acre, which formerly would not produce over 4 or 5 bushels; and he gives it as his opinion, that marl is the very best manure that can be applied to land, both on account of its durability and productiveness.

Mr. Henry Davis, in the same neighborhood, has also been experimenting with marl with entire success. He has cotton growing on fresh land, well marled, the stalks of which are six or seven feet high, and well filled with bolls.

Land, with marl beds on it, has suddenly risen in price, and cannot even now be purchased for many times its former valuation. All are deeply impressed with its intrinsic worth, and anxious to renovate their worn out lands from these inexhaustible mines of nature's own formation. May we not justly hope that a new and better era is dawning upon our State—an era of improvement, not of exhaustion—when her sons will cling to the homestead of their fathers, and with patriotic ardor improve the old domain, apply the fructifying marl, reclaim the "old fields," and make them once more blossom and bear, and yield to the sustenance of man?

We have heard of one gentleman who, a year or two ago, bought a tract of land, having marl on it, for $1500, and would not now take $6,000 for his purchase. Indeed, the spirit of improvement appears to have seized upon the whole agricultural community in the vicinity of the marl beds. Another highly intelligent, extensive and successful planter, we are informed, is preparing to build a steam tow-boat, for the purpose of supplying himself with marl and carrying his crops to market. This spirit of enterprise and practical improvement, is truly gratifying to the philanthropist and patriot, and augurs well for the future prosperity of this section of the State.

"Every man of us down here," says the writer of the letter from which we glean many of the facts above stated, "from Henry Davis's to Harllee's, is hauling out marl as fast as he possibly can. I have two ox-carts going, and will in a day or two have three more, and every negro I own, engaged in this business—some digging it up, and others hauling and spreading it upon the land. Mr. L. M. White has been at it for about a month before I commenced, hauling out with a one-ox cart, and spreading it on his fields. Just come down and go with us over our farms, and you will agree with us that it is by far the best manure that has ever yet been found out, or ever will be discovered, while the world lasts and the earth is cultivated."

We are informed, that contracts for any considerable quantity of marl, may be made for its delivery at the Cheraw landing, for five cents a bushel. In Virginia, the quantity used to the acre is from one to two hundred bushels, and when this quantity is applied, the land resumes its original fertility, and becomes almost inexhaustible. It may now become a matter of calculation with our planters, whether this would not be a profitable outlay of capital. It is probable, if the demand became extensive, the price of delivery would be reduced, as the supply is said to be inexhaustible.

PREPARING COTTON FOR MARKET.

MR. EDITOR—In the first No. of the present volume of the Cultivator, I promised you that I would, at a suitable time, give my brother farmers, through the columns of your agricultural paper, my system of preparing my cotton for market. Being this far on my way home from the West, where I have spent the summer on an agricultural tour, I now comply with my promise of giving my plan of putting up my cotton, and I must first say that it will be found extremely difficult for the cotton planter to prepare the great Southern staple as it should be done, while he is all the time going for quantity, and not for quality; but still he may, however large his crop may be, prepare a portion of it as it should be, if he will take the necessary trouble and pains.

But to the point. I take all the care I possibly can in picking it out of the field, endeavoring to keep up with the opening as near as possible, taking all the pains I can to pick it clear of trash: I then dry it thoroughly on a scaffold, keeping one hand picking it over while the cotton is drying: I then pack it away cleanly in bulk, and suffer it to remain until it becomes heated. My finest cotton last year remained in bulk about two months—this year I think of letting it remain three months in bulk. After it has remained long enough for the oil to be drawn from the seed into the staple, to give it that beautiful cream color so much admired, I then commence ginning. I gin it very slowly on a fine saw-gin, picking it over again as it is ginned, so as to get out any remaining trash that may be in it. I have a flue that is fixed to the gin, through which the cotton passes, after leaving the brush. The flue is eight feet long, and is so constructed as to let all the dirt and trash drop in a box below, as the cotton passes over the fingers of the flue: the cotton passes from the flue into the cotton-room. I never suffer much to be packed in the room before I commence putting it in bales: this is done with the greatest care. I press it down with a screw, instead of treading it with feet, as every pressure defaces the cotton to some extent. My bales weigh about 480 lbs. I sew up my packages very nicely, and put up my cotton in the best of bagging.

Now, I request the farmers, before they condemn my plan as too tedious, to make the trial, and they will find it a money-making business. I would, however, state, that I make three qualities of cotton: my first and second qualities, I plainly put my name on, and the place of my residence, the third quality I put the letter M on.

I would have waited until I reached Eufaula, Ala., before I wrote, but presuming that some of the growers of cotton might desire to try my plan, and as the season was passing away, I determined to write from this place. At a future time, I will give you some account of my trip to the West.

With the greatest respect, yours, &c.,

ALEXANDER MCDONALD.

For the Southern Cultivator.

A SHORT CHAPTER OF EXPERIENCE.

Transplanting Peach and Apple Trees; Smut in Wheat—how prevented; Rust; Charcoal; Coal-tar and Soot; Tar and Sand; Lime will kill Wheat; What is the best Method of Improving Fresh Lands?

MR. EDITOR—Some time since, I saw it announced in your paper, that it was a good method, to keep worms from the roots of peach trees, to put half a gallon (if I remember correctly) of ashes around the roots when transplanted, and a less quantity every spring thereafter upon the ground around the tree.

Last spring, I had a quantity of peach and apple trees set out, after the common mode, of which three of the former died. Some short time afterwards, I had a few peach trees of a rare variety, and some few apple trees, to set. As I prized them highly, after placing the tree in the excavation made for its reception, I deposited perhaps one gallon of ashes around the roots, then a layer of dirt, then a quantity of water, then filled the hole with ashes and dirt, and applied more water. The result was—every peach tree died; and but one apple tree looks like doing well, while one or two more are showing only a faint prospect of ever budding again.

You will perceive I used more ashes than was recommended, which shows the importance of one's going by the directions, as prescribed to him, in following out an experiment.

Two years since, I rented a piece of land to sow in wheat, which was cut and thrashed while wet. It was pronounced, by all who saw it, to be the blackest they had ever seen. This I had washed well, but could get no white flour. Several writers in your paper recommended blue-stone as a preventive—no one of them, I believe, gave the relative portions of each, and the length of time the wheat should be soaked. One said one pound of blue-stone to five bushels wheat—another said neither blue-stone nor brine was a preventive, but the wheat should be soaked in both of them—a third said, if kept in a cool place it would keep two or three days. I therefore made a solution of salt, (it should be made strong to bear up the light wheat and all the oats which may be in it,) poured slowly into it one bushel of wheat, frequently stirring it, and skimming off everything that would swim, and let it soak six hours. I then put the wheat into another tub, poured in nearly water enough to cover the wheat, then emptied in a solution composed of three or four ounces of blue-stone, which had been dissolved in warm water, stirred it up well, and let it set twelve hours. I used the same brine by adding a little more salt and water, and the same solution of blue-stone by adding three ounces more blue-stone, for every bushel of wheat sown. I also rubbed the wheat in ashes before sowing it. I often examined it, and only found one head of smut in ten or twelve acres.

If it be said the dark nights in October kept out the smut, I here add, that I sowed in the same field, and on the same day I finished the other, a half a pint of the prettiest and the whitest-looking wheat I had ever seen—which produced about a hundred heads of smut, because I did *not soak it*.

In thinking on this subject, I have thought the wheat should be soaked in blue-stone first, as a considerable quantity of salt adheres to the grains, which, if sown, would probably add to the fertilizing properties of the earth.

There is another difficulty—the rust. Some writers say the French have prevented this disease by using powdered charcoal—yet none of them, whose productions I have noticed, state the quantity the French use for that purpose.—As we have no machines for that purpose, would it do to dampen the coal, and beat it up in a large trough?

The Agricultural Society of South Carolina, in their report of 19th June, state, "We would recommend, in the highest terms, the use of the coal-tar to preserve the seeds from birds." Nor have they stated the relative quantities of each, coal-tar, soot and corn.

Some five years since, tar and sand were recommended to me for the same purpose. I then prepared my tar, sand and corn, and planted ten acres, not one grain of which have I seen since. This also reminds me of a gentleman in Monroe county, Ga., who prepared his wheat in lime, and sowed forty acres, none of which ever came up. Persons who recommend a new project, should also give the proportions, time and manner, of carrying out their views.

There is one question I wish to propose to some of your correspondents. I am now making my fourth crop on gray land, with a clay foundation near the surface, with a few rocky spots, though they are small. What method shall I adopt to improve the land to the greatest advantage with the least expense? Would it do to sow down in rye, corn, buckwheat, or peas, and turn the green crop under? If so, at what time of the year, and what kind of a plow? Yours, &c., P.

Salem, Russell county, Ala.

For the Southern Cultivator.

SMUT IN WHEAT.

Mr. Editor—I discover that you have several correspondents, giving various means to prevent the smut in wheat; and as this is an important matter, I will give you one.

My neighbor, Alexander R. Bell, of this county, has long been considered a great wheat grower, and a great many persons are in the habit of sending some distance to purchase his wheat, on account of its superior quality. About the time he was cleaning his crop, I happened in, and he took me to his barn to show me his great yield: I was astonished to find that there was no smut in his wheat, and remarked it to him. He said no, I never have the smut in my wheat. I inquired the means of preventing it, and he gave me the following:—Sow your wheat the first of October, and when you harvest, let what you intend to make seed of, remain five or six days longer in the field before it is cut, and by this means all the grains will be perfectly ripe and good. This is all he does to prevent the smut, and he never has it in his wheat.

I stated that I had went out to see his yield, which I found to be fine. He sowed one bushel and a peck of wheat, and it yielded him forty bushels and a fraction over: it was as nice and as fine wheat as I ever saw, and made good flour. Yours, respectfully, W.

Columbia county, Geo.

From the Boston Cultivator.

THE FARMER'S ODE.

Let Commerce spread her flowing sails
And Trade her path pursue;
Without the Farmer what avails,
Or what without him can they do?

Let learned Divines and Lawyers boast,
Let Physic follow in their train,
The Farmer's skill is valued most
In making golden sheaves of grain.

Let Statesmen rack their brains with care
Some mighty project to fulfil;
The Farmer's wiser projects are
His flocks to feed, his grounds to till.

His orisons at early dawn,
To the Almighty Power he makes,
Then treads the dew-bespangled lawn,
Or pleasure in light labor takes.

He hears the robin's early song,
And ruder notes of cheerful swains,
While heedful of his crops, along
He travels o'er his own domains.

A stranger he's to fretful care;
No busy schemes perplex his life,
Contented with his homely fare,
His children and a prudent wife.

He labors to improve his soil,
While Ceres shows him her regard,
And blesses all his careful toil,
In fruitful crops for his reward.

No prodigal nor careless waste,
On his domain is ever found;
With open hand he yet will haste
To help the poor till they abound.

And now his earthly labor's past,
And old in virtue he has grown;
To crown his well-spent life at last,
Kind heaven shall claim him for its own.

SELECTIONS, EXTRACTS, &c.

From the American Agriculturist.

ORGANIC IMPROVEMENT OF DOMESTIC ANIMALS.

Sheep and other animals were subdued and domesticated long before their biped captors and masters were able to keep a record of their doings for the benefit of their posterity. Hence we know little of the original stock from which our domestic animals have descended, and less of the early treatment they received at the hands of our own progenitors. Nor is this information important. It concerns us mainly to understand how a change of food, temperature, and of all surrounding circumstances, will either *improve* or *deteriorate* the organic structure and natural functions, which transform for the practical farmer his cultivated plants, their seeds and roots, into wool, beef, pork, milk, lard, butter, and cheese. That there is a wide difference in the results obtained, by the operation of this living machinery in different animals, no observing man can doubt. Of two cows of equal weight, and consuming equal quantities of food precisely alike, one will elaborate for its owner eighteen quarts of milk in twenty-four hours, while the other can form but nine quarts in the same length of time. A pig, whose organization is apparently nearly perfect, will elaborate from a given amount of raw material, twice as much flesh and fat, as another whose respiratory and assimilating machinery are very defective. Experience and science alike demonstrate the truth of the remark, that it takes fifty per ct. more food to produce a given amount of muscular strength and power of locomotion in one horse or ox, than is required in another. Animals that had a common parentage ten generations back, now possess not only widely different forms, but organic and constitutional peculiarities, of great importance to those that may become rich or poor, according to the well or ill management of their herds and flocks. Eminent success alone attends skill in the breeding and keeping of domestic animals. This valuable skill is acquired by close observation, and studying the uniform laws of nature that govern the growth, maturity, and decay of organic beings. The most important and material changes in the development of the organs of animals, and in the function of each organ, are made during the period that elapses from the first formation of the embryo, to the maturity of each living complex structure.

"As the twig is bent, the tree's inclined."

The plasticity of young animals and plants, and the extreme changes that may be wrought in their forms and habits, are truly wonderful. The human brain itself can be moulded in infancy into any shape to suit the whim or taste of a "Flat-Head" or a "Round-Head" Indian. Nor is there a single mental or physical function in the human system, that may not be either improved or impaired by the good or bad influences which may be brought to bear upon it. The science of physiology is a noble science. It enables cultivated reason to trace results—the products of animal life, such as flesh, fat, milk, and wool—back to their known causes and elements.

I can hardly expect to give you even an outline of the organization and workings of this complex vital machinery. There are, however, a few cardinal points in this matter, which I will endeavor to make clear and intelligible.—One is, that no animal or plant can possibly transmute one simple elementary substance into another. If a hen be fed on food that is quite destitute of lime, the organs of her system cannot form an egg-shell, so if a child, colt, or calf, be kept on food that lacks phosphate of lime, its bones will be soft and cartilaginous. No other minerals can be changed into lime or phosphorus.

Animal fat is a compound made up of carbon, hydrogen, and oxygen; and no other simple elements can possibly make it. Lean meat and wool contain the same elements, with the addition of nitrogen, sulphur, and several other earthy ingredients in minute quantities.

Knowing that no animal can create anew one particle of matter, and that each compound product has its peculiar constituent elements; knowing also how much of those elements is contained in any article of food, we can judge of its fitness or unfitness to produce either bone, muscle, fat, milk, wool, or any other animal product. In other words, we can wisely adapt our means to the ends we have in view.

Suppose a farmer had one hundred hens in his poultry-yard, and he desired them to lay as many and perfect eggs as possible. Would it be an unreasonable prescription to say to him that "you must feed them liberally on food which contains not only lime, but all the elements of the contents of an egg-shell in a concentrated form? Deny not the raw material, if you expect the bird to elaborate for your table, or for market, a large product of this article of human food."

Is it anything extraordinary that a race of cows, whose mothers for many generations have had their milk-forming organs largely developed by being fed on food well adapted to that end, should secrete far more milk from a given amount of raw material, than a race of wild cows, whose lacteal glands had been denied all the advantages that result from quietude, rich pasture, and regular dry milking?

A sheep consumes several pounds of food daily. Of this, at least eight ounces are composed of the constituents of wool. Now if the capillary organs of this animal transform only two per cent. of these elements into wool in twenty-four hours, then in one hundred days the sheep will grow one pound of this valuable product. This will give a fleece which will weigh 3 65-100 lbs. in 365 days. Is it not practicable so to improve the vital action of the wool-forming machinery of our twenty millions of sheep in this country, that this machinery shall transform four instead of two per cent of the raw material of wool into that substance? That this organic machinery is perfect, no one pretends to doubt; or that it has already been greatly improved, is not denied. The manufacture of wool out of its constituent elements, is a branch of science of great importance to the farmers of the United States. They possess an inexhaustible quantity of the raw material of wool, and enjoy every advantage for its profitable production. To develop the capillary organs of the sheep, the animal should have a warm, or rather a comfortable, well ventilated apartment in winter—should be kept quiet throughout the year; that is, it should not be compelled to travel too much to find its food. It should have the organs that form this animal product *at all times* stimulated to a preternatural action, by having the arteries that convey nourishment to these organs, preternaturally loaded with the elements of wool. A plant grows best in a soil rich in the elements of such plant. So, too, with an animal, and especially a young animal, elaborates the most flesh and fat when its blood-vessels are best supplied with the elements of those products.

Clover, oats, turneps, beans, peas, and other leguminous plants, contain more of the constituents of wool than timothy, herdsgrass, potatoes, and corn. All animals should be fed regularly, and particular attention should be paid to their health and comfort. It is, perhaps, needless to say, that every improvement in the practical workings of all this living machinery can be transferred from parent to offspring by judicious breeding.

The action of the respiratory organs in all domestic animals has a material influence upon the formation of fat, muscle, milk and wool. The lungs never cease night nor day to expel more or less of the elements of animal food through the windpipe into the air, in the form of carbonic acid and vapor. The organization of some animals is so defective that they consume in this way a much larger quantity of the constituents of flesh, fat, milk and wool, than is necessary or profitable. The more an animal exercises, the faster he breathes, and other things

being equal, the poorer he becomes; because, instead of nourishing and supplying the waste in the system, the elements of the food escape in a larger ratio from the assimilating organs. The food of animals consists essentially of carbon, hydrogen, oxygen, and nitrogen. The first escapes through the lungs, the second and third escapes in vapor, perspiration and urine, and the last (nitrogen) also escapes by the kidneys. Hence, a cow, when driven twelve miles a day, never gives as much milk as she does when consuming the same amount of food and remaining quiet in a pasture or stall. It is an easy matter to enlarge or diminish the size of the blood-vessels that convey the elements of milk to the lacteal gland of the cow, or the vessels that convey the elements of wool to the capillary organs of the sheep. It is not difficult to increase both the size and strength of the muscles of a colt, or of a young bullock. Like the enlargement of the muscles in the arm of a blacksmith, judicious exercise must come to the aid of judicious keep. D. LEE.

Albany, April 30, 1844.

From the Southern Agriculturist.

EXPERIMENTS WITH MARL.

We are very happy in hearing, that many planters in various parts of the middle and lower districts of our State, are seriously marling their highland crops, in the cultivation of corn, cotton and peas. The number of acres marled by each, is no accurate test of the zeal, faith and industry of the planter—his relative ability to plant more or less—the facility of procuring his marl, and of carting it to his fields—with a variety of minor considerations; all have great weight in our estimate of his enterprise.

In the last April report, published by the Agricultural Society of Black Oak, in St. John's Parish—a section of the State abounding more with marl than almost any other—they state that upwards of 1,200 acres are under cultivation, having been marled in the preceding year. Of these, they state the number of acres marled on twenty-five of the plantations, amounting to 1,113 acres. This report is entitled to the utmost confidence, it being from a Committee of Inspection, in which are some of the most practical, liberal and enlightened planters in the State. They evidently discriminate, not giving the names, but declining to publish the experiments of some, who, from want of information or other cause, are not conducting these experiments properly. They have excluded 100 acres of marled land, probably on this account, and others may have escaped their notice altogether. They appear, also, to have excluded all who applied the marl this year to the present crop, because it could not have had a sufficient time to become incorporated properly with the soil. We have heard of some persons, and in that neighborhood, also, who say that they are marling their fields, and only apply from ten to twenty bushels per acre. This may proceed from want of information on the subject of marling: it probably will, by its total failure, mislead and discourage them, and such of their acquaintances as are equally ignorant of its inadequacy. We suggest that the Agricultural Societies should warn all within their influence, of the certainty that such experiments will fail, and issue handbills showing the proportions of marl to different descriptions of land, and to the quantity of vegetable matter and of animal manure, that it may have to act upon—reducing them to the best state for nourishing the crops.

One gentleman, well informed in other respects, said that he was about to procure a boatload of marl for his field this last spring: on being asked how he intended to use it, he said, that he would try it fairly, and put at least a double handful of marl to each corn hill. If he did this, he probably lost his crop, and would blame the marl for it, instead of blaming his own inexperience.

Every planter in the middle and low country, should put into his overseer's hands a pamphlet, teaching the advantages of marl, and the best mode and proportions in using it; insisting that the addition of vegetable matter is indispensable to the beneficial use of marl and other stimulating manures. A.

AGRICULTURAL SOCIETY OF S. CAROLINA.

REPORT OF THE STANDING COMMITTEE.

The Standing Committee of this Society, on the expenses incurred on Produce of the State, would beg leave to submit statements relative to the sums expended on domestic imports:

They do not wish to touch on any speculative doctrine of political economy, involving the necessity of mutual exchanges for reciprocal advantage, but propose to show in what articles our money is expended, and whether any balance remains. The Committee leave it to the good sense of the Society, and the community in general, to determine, how far many of these expenditures are inevitable, or whether they may be moderated for the good of the State. In the extended trade between the North and the South, it is very difficult to ascertain the accurate amount of what we buy, and the statement now submitted does not pretend to effect more than approximate to the truth. It may, however, give some clue to the labyrinth of domestic trade, and invite those well informed on particular items, to add such correction as may finally lead to something like a correct statistic. The object of the Committee is simply to exhibit a debtor and credit statement of our receipts and expenditures, as a suggestion of the propriety of producing for ourselves, much of what we now purchase, so as to retain at home so much of the proceeds of our labor as will enlarge the resources and comfort of every family in the State.

To strike a balance, the value of exports must be stated.

Export of 60,500,890 lbs. Cotton,	$6,000,000
" 80,000,000 lbs. Rice,	2,000,000
" Lumber and other commodities,	500,000
Total Exports,	$8,500,000

IMPORTS OF 1843.

Sugar,	5,917 hhds.	5½ cts.	$383,922
Coffee,	38,294 bags,	8½ or $13	501,722
Molasses,	4,359 hhds	24 cts.	135,000
Flour,	52,000 bbls.	$5	260,000
Corn,	300,000 bushels,	50 cts.	150,000
Oats,	100,000 "	30 cts	30,000
Peas,	40,000 "	62 cts.	24,000
Hay,	24,826 bundles,	87 cts.	74,478
Bacon,	5,000 hhds.	6 cts.	300,000
Lard,	20,000 kegs,	6½ or $3	60,000
Butter,	18,750 kegs,	$12 each,	225,000
Salt,	91,122 sacks,	$1 30	118,458
Cheese,			30,000
Plows and Garden Implements,			20,000
Northern Hardware,			250,000
Machinery,			200,000
Horses, Mules, Cattle, Hogs,			1,775,000
Building Materials, Lime, Granite, Carpentry, &c.,			150,000
Equipages,			150,000
Furniture,			50,000
Shoes,			1,081,700
Hats to ¼ of 256,000 whites at $4,			340,000
Dry Goods,			2,000,000
Foreign Imports,			1,588,852
Total,			$9,808,932
Travelling expenses must be computed as one of the regular drains to the State, 2,000 persons at $300,			600,000
Total Imports,			$10,408,932

The discount against this sum, for re-exportation, may be thus estimated.

Sugar, 383,922 Coffee, 501,722 Molasses, 135,000	1,020,644,	deduct ¼,	$255,161
Hardware,	250,000	deduct ¼,	62,500
Lard,	60,000	" ¼,	15,000
Foreign Imports,	1,553,852	" ⅓,	526,284
Dry Goods,	2,000,000	" ½,	1,000,000
Deduct from $10,493,932 this am't,			1,858,945
			$3,639,987

This exhibit of imports has been compiled from the account current files of the Mercury and Courier for 1843, corrected as far as practicable by merchants most likely to possess accurate information. The importation of corn last year, was comparatively small, owing to the failure of the North Carolina crop; but in years past, has considerably exceeded the amount specified, though at present on the decrease. The greater portion of our Sugar, Coffee and Molasses, particularly the first two, is received coastwise, notwithstanding freight and distance. Much of this import is distributed throughout the State. The aggregate of all these items, shows a considerable balance against the State, moderated by the probable discounts for re-exports to Georgia, North Carolina, Tennessee, and Alabama.

Although the cost of the Sugar, Coffee and Molasses, is merged in the foreign imports, yet so large a portion comes coastwise, and does not appear on our Custom-House books, that a deduction must be calculated as well from those items, as from the foreign imports. From the foreign imports, a third may be deducted for re-exportation, and from the dry goods at least one half. The amount of dry goods from the North is probably more than two millions, but it is impracticable to arrive at an estimate. The importation of dry goods to Columbia, Georgetown, and Hamburg, enter considerably into our calculations. Independent of our catalogue of expenses, a considerable amount is spent for beef, pork, fish, baskets, pails, mats, and a thousand other articles. The fact that we have no surplus, is confirmed by the stationary amount of coin in the country. If our exports exceeded our imports, the surplus would be paid for in specie, but the statements of the Banks show, that in an average of years, the amount of coin imported and exported, balances—incontestibly proving that we are not in a prosperous condition. Again—if what may be said of a community of individuals, may reflect some idea of the condition of a State or nation, and we refer for an example to the planting interest in particular—it will be established that the planters are generally incumbered with debt and complaining, yet tributary everywhere for many of the necessaries of life. As we are essentially an agricultural people, it is fair to conclude, a sympathetic influence pervades other sections of society, and that our habits and pursuits require reform.

All which is respectfully submitted.

R. W. ROPER, Chairman.

From the Farmer's Cabinet.

IRRIGATION.

It is said that "Van Helmont planted a willow, which weighed 5 lbs., in a pot containing 200 lbs. of earth. This he watered for the space of 5 years, and at the end of that time the tree was found to weigh 169¼ lbs., while the earth in which it had stood, being dried as at first, was found to have lost only two ounces. Here, then, was an increase of 164 lbs. weight, and yet the food of the plant had been water only."

If, then, watering is attended with such great results in the case of a tree, is it not reasonable that, in the case of herbage, it is still more important? It is not by any means, at this day, contended that the only food of plants is water; but water generally holds in solution minerals, which are food for plants; and it carries those dissolved minerals to the roots of plants, exactly where they are wanted. Land may have all the necessary minerals and manure, indispensable to plants, and yet in a dry season the grass won't grow; how important, then, is irrigation, if only to dissolve those minerals.

Mr. Liebig, I think it is, who says that in Germany, lands which have formerly been nearly barren, have been made, by irrigation, very productive. The mode adopted in this country for watering meadows, is considered by many as too expensive: they have consequently plowed up their meadows and do not water at all. What the mode of watering is in Germany, I do not know, but I would respectfully suggest the use of a wheel mentioned by Dr. Arnott, in his Elements of Physics, by means of which, "streams are caused by their own action, to lift a part of their water into elevated reservoirs." For the purpose of watering meadows, where streams lie high, a small portable wheel of this kind, of about three feet in diameter, would save the labor of making a great many small channels. But where the water is situated low, and

is required to be raised a considerable height, "a large water-wheel is placed so that the stream may turn it; and around its circumference buckets are attached, to be filled as they sweep along below, and to be emptied into a reservoir as they pass above; or instead of buckets, the spokes of the wheel are themselves made hollow and curved, so that, as their extremities dip into the water at each revolution, they receive a quantity of it, which runs along them as they rise, and is discharged into a reservoir at the centre. These are called Persian wheels, but they are in common use on the banks of the Nile, and elsewhere."*

I would suggest the formation of agricultural clubs, to make trial of such wheels, and for other improvements. All the expense of such a wheel, defrayed by a club of ten or twenty members, would be so small to each member, in comparison with the great object gained, that the expense would be no objection. A wheel for the purposes of farmers generally, would not cost more than five dollars. RUSTICUS.

Lancaster county, Pennsylvania.

*These wheels are frequently used in this country for the purpose of raising water for tan yards.

From the Central New York Farmer.

IMPROVEMENT.

MESSRS. EDITORS—After the very polite and flattering invitation you have given me, publicly and privately, to write for your paper again, I should do injustice to you and violence to my own feelings, did I not comply with that request. I am willing, yea, anxious to do all that is in my power to forward the now advancing interest of agriculture. In this letter are the sentiments I entertain and cherish relative to this great subject. I have ever held that the farmer should progress with the progressing spirit of the age, and in order to do this, means must be employed commensurate to the obstacles to be surmounted and end to be attained. That farmer who is willing to beat and beat the beaten track, will be about as able to compete with those whose motto is "excelsior," as those who are fifty years behind the time in manufacturing clothes. That one who will unhesitatingly assert that he knows all about farming, and that there are none who can teach him, shows to an enlightened farmer that he is basely ignorant of the business which he disgraces by his bungling mode of conducting his affairs. That man who says an agricultural journal is a money-making machine *merely*, convinces me at least that he never had one in his hand—that he knows nothing of their aims or accomplishments. He who is too illiberal to give 50 cents or a dollar a year for a paper, which might be worth fifty dollars to him, will not be very apt to expend much in improving his farm. My friends, men who will indulge in denouncing such noble public spirited men as Buel, Bement, and a host of others, as asking self-aggrandizement—gratifying their thirst for public applause, and only aiming to fill their pockets, having gulled the people into their measures, to buy their stock, take their papers, and follow their system of farming; I say, sirs, such men must be possessed of a spirit contemptible in the extreme. They are no more fit to be farmers than a hottentot is to be President? Fit, did I say? language is inadequate to say of such men what I honestly think. Have they no ambition? Are they cherishing the sentiment that farming is mean, and not respectable? They know nothing of the *true* farmer. Do they feel that they are overlooked by the "professionals?" Rise, thou sluggard, and come forth with all that dignity of which the intelligent farmer is possessed! Assert your rights—claim your place due you in society, and drive from your bosom the thought that tilling the soil is mean. Mean to till the soil!! The farmer a bondsman! I answer those, and those only, who make themselves such for lack of energy.

"We hold these truths self-evident, that all men are created equal:" such was the feeling of our forefathers, and such the feeling of the philanthropist of the present day. Legislation comes to our aid, protects our industry, and encourages our enterprising spirit—she fosters the germ which the most brilliant talents of the world have watered. Sirs, the whole superstructure of national greatness rests upon the intelligent portion of the farming class. Is it not wisdom for legislation to protect her interests? Those nations who have given agricultural concerns and men the highest place in public affairs, who have acknowledged their worth, respected and protected their civil, religious and political rights, have been the most happy, prosperous and independent nations of the earth.

Men spend whole lives in the cultivation of the intellect: this is well and commendable when used for good purposes. Men make attainments in every branch of business very rapidly; so rapidly that it almost taxes our credulity to believe what our eyes and facts convince us as truth. Why is it? What means are employed? From ten thousand sources we hear the reply in thunder tones, application and experiments combined, have effected all this. But the experimentalist is to be set aside as seeking self-aggrandizement, and to be looked upon as getting above his business. But such sentiments and their supporters are soon to be forgotten, while those who are fast surmounting these difficulties and prejudices will have a place in the hearts of their countrymen alongside Washington and kindred spirits. The one leader of the revolution of '76—the other leader of an agricultural revolution of the present age. One had to contend against superiority of numbers and wealth—the others against nine-tenths of those who are theoretically engaged in the same business with himself. The one was victorious, and reaped a rich reward; the others are destined to achieve a signal victory, and receive the thanks and applause of coming generations for the obstacles they have and are still to surmount. Their march is onward and upward. Men of brilliant talents and noble souls are putting hand to the work, and begging those who are nominally farmers, to join with them and help to dispel the bug-bear clouds which hang in imagination about the pathway of the farmer. We know full well of the effects which early training will exert over a person. We are aware that it binds all, more or less, to the customs and maxims of our predecessors; but farmers must think for themselves, or they will ever continue to beat the almost adamant track of their ancestors.

England is much in advance of us, and will continue to be until we take the same or similar steps to rival her. Has a bountiful Providence favored her more than us? Are her lands better adapted to tillage than ours? Is her climate more genial to the farming interest? Has she men who are able to rival ours in profound thinking or useful inventions? Experience, history and common sense, all combine to answer no!! Yours, truly, W. S.

Binghampton, August, 1844.

NEW YORK AGRICULTURAL INSTITUTE.

The object of this Institute is to afford facilities to those desirous of entering upon a course of study preparatory to farming, the advantage of which has been made evident by the researches of a large number of scientific men and experienced agriculturists.

The necessity for an improved system of husbandry is apparent from the decreasing harvests of many parts of the sea-board States. The present reckless tillage of too many of our farmers, reduces the finest lands to sterility by a succession of exhausting crops; and emigration is the consequence. These evils, unless speedily checked, will destroy our prosperity; for the cultivation of grain is becoming unprofitable, and too great an importation of food from the west would in a short time absorb the resources of the wealthiest eastern States. The only effectual remedy is the improvement of cultivation; not a mere application of tons of manure, and shiploads of lime, per acre, but their economical use. Common manuring has been practised from the remotest antiquity, and good crops have been obtained; *but it is the judicious addition of such substances as are necessary to the soil, in proper quantity, with a view of attaining a definite purpose, that constitutes professional agriculture.*

To individuals, this system will prove a source of wealth, even on ordinary lands. Less capital is required to hold the same surface, because every acre yields a revenue: two or three crops can be taken annually, where one is now scarcely attainable: the heavy expenses of manuring and keeping stock are reduced to a trifle; and machines can be made to perform much of the work now in the hands of laborers, sustained at a heavy expense. In maintaining sheep and cattle, the use of food properly prepared and selected for its chemical value, will reduce the charges to the lowest point, while the development of the animals is better secured.

By requiring a preliminary course of studies, and introducing the exactness of science into agriculture, it will rise to the dignity of a PROFESSION, and be regarded as a suitable calling for persons of liberal education, instead of an obscure art. Numbers of talented young men, who, after leaving college, see no other roads to distinction or wealth but medicine, engineering, law, or divinity, will direct their energies towards the improvement of farming—a change not less serviceable to the art than advantageous to themselves; whereby they exchange the uncertainty of competition in employments already overstocked for the certainty of systematic agriculture, chemistry, analysis, and physiology; and measures have been taken to introduce a course of instruction in agricultural mechanics and rural architecture. These are distinct classes, so that students can attend any separately.

In *Agriculture* will be taught all facts in chemistry, geology, and botany, useful to the farmer—the drainage and preparation of soils—the collection, storage, and preservation of provender and fruits—the feeding and improvement of stock—management of orchards, vineyards, &c.—the preparation and economy of manures, both organic and mineral, with their action and causes of success or failure. In short, all the topics embraced in the courses given by Professors of Agriculture in European colleges, will be discussed.

Chemistry, as an abstract science, is taught by Professor Draper in the University.

Anatomy and Physiology, by Professor Pattison. This course is directed more especially to an examination of the structure and functions of the human body, and may be attended with great profit to the student.

Analysis of Soils, the ashes of plants, and manures, will be conducted by the students under the direction of the subscriber, with such assistance as may be required.

The city of New York offers numerous advantages in carrying out the objects of the Institute—the facility of access—the high cultivation of many farms, nurseries, &c., in the vicinity—the conservatories and market gardens—the large collections of farming implements—the choice seeds obtainable—the numerous artificial and mineral manures that can be examined—constitute it the best locality in the United States. Good board and lodging near the University can be had for from $2,50 to $3,00 per week.

The *Institute* is situated in the University of New York. It opens the first Monday in November, and continues in session until the first of March. This period has been chosen for the accommodation of those engaged in farming. Fees for the course on Agriculture, $20; for Analysis, $30; for both, $40. The courses on Agriculture and Analysis are conducted by

D. P. GARDNER, M. D.,
Formerly Prof. of Chemistry, &c., in Hampden, Sidney College, Va.

For further information, address, post-paid, Dr. Gardner, 412 Fourth-street, New York.

Brine for Sheep.—When the salt is allowed to get wet in troughs, it will kill sheep.

From the Western Farmer and Gardener.

SPIRIT OF THE AGRICULTURAL JOURNALS.

Hay.—According to Sinclair, the nearer it approaches to ripeness, the more nutritive matter it contains. Clover should be cut when the flowers first begin to fade.

Turneps among Corn.—When from any cause corn is so thinned as to be only half a crop, make clean the ground and sow turneps. This will help to make up for the loss.

Table of the number of bushels of wheat, barley, oats and rye, to each individual in the different countries.

In Great Britain,	12	bushels.
Denmark,	20	"
Prussia,	12	"
Austria,	14	"
France,	7	"
Spain,	5	"
United States,	18½	"

This was ascertained in 1828, and it is probable that the proportions have not much changed.

Fall Fodder for Cattle.—For those who have only one or two cows and have a plat of ground, when the grass begins to decay, sow some Indian corn in drills, filled in with manure if necessary, and covered slightly. Keep it free from weeds, and every night and morning in the fall you can cut an armful, and it will come out in extra quantity and quality of milk.

Remedies suggested against the Curculio.—It being ascertained that those insects do not fly far, use the galvanic battery, a ring of copper and one of zinc, or a cup of tin surrounding the tree, in which put lamp oil ⅛ inch deep. It will prove an effectual barrier. Burn all the punctured plums, too, that fall off, to diminish the insect the next year.

Sweet Apples vs. Potatoes, for Hogs.—The apples will be found to make the most pork, and are easier raised; but they should be of the best kind, and ripe, as hogs are fond of grafted fruit, as well as men.

Chess and Wheat.—The doctrine is now exploded, that wheat will produce chess, or chess wheat; but this is certain, that when the earth is turned up, many seeds of weeds and other things are turned up with it.

Conversion of Lard into Oil and Stearine.—There are in Cincinnati not less than thirteen factories, in full operation, making from 300 to 2,500 barrels each in a season, or 100,000 gallons. The oil sells at sixty cents a gallon by the barrel, and seventy-five cents by retail. The stearine made by one establishment amounts to 750,000 pounds per annum, two-thirds of which (the summer) is suitable for making candles.—This stearine sells for seven cents per pound, which is used for culinary purposes, is equal to the best leaf-lard, and sells for six cents per lb., when well put up in kegs for shipping.

Bugs on Vines.—Almost any kind of dust strewn on vines has a tendency to keep off insects, but a new dusting will be necessary after each shower.

Fall Transplanting of Fruit Trees.—From the 20th of August to the last of September, has been found a successful time for transplanting strawberries, (these may be done earlier,) pears, plum and apple trees, currant and raspberry bushes—this according to the season, and when the summer wood has ripened. Take two spadings of top soil to mix with the roots; make the hole a foot wider than the roots of the tree. Previous to taking up the tree or bush, remove every leaf with a sharp scissors. Take up every tree in the morning of a clear day, and place the roots in a tub of soap-suds; let them remain till the afternoon, or even twenty-four hours.

Seed Potatoes.—These should not be too ripe, as they are apt to be diseased.

The Blight Insect, or Scholytus Piri.—Mr. Samuel Hatch, of Marshfield, N. Y., showed limbs of apple trees girded beneath the bark by a small beetle. It attacks pear trees, apple trees, and quince trees, and works secretly under the bark, cutting off the source of the ascending sap, and ruining the part of the limb which is above its operations. An apple tree limb was brought to the office of the Central N. Y. Farmer, which concealed thirteen little dark brown beetles in each joint or bud. On being shown to Dr. Harris, he had no doubt it was of the same species as the pear tree destroyer. Limbs thus infested should be cut off immediately and burned.

Salt on Hay.—About four or five quarts per ton, is sufficient; more may produce too much thirst in the animals eating it.

Cure for Burns.—After opening the blisters, if formed, dip the part in cold water, and then plunge it still wet in cold water for a minute or two. This prevents the air from getting to the burn.

Saltpetre.—Five rows planted with corn, soaked in a solution of salts of nitre, or saltpetre, yielded more than twenty-five rows without any preparation. No worms touched the first.

Gapes in Chickens.—This is caused by worms in the throat. Take a small feather and strip off the web, except about an inch and a half at the top. Wet the end and turn it back. Let a person hold the chicken on its back, extending its legs. The operator takes hold of its head with his left hand, placing the thumb and forefinger on each side of the bill, so as to hold the mouth open. Draw the neck out gently but firmly; introduce the feather over the tongue, and watch when the chicken breathes, which opens the windpipe; then enter it quick, and do not be afraid after the point is entered. Push down gently two or three inches, and then withdraw the feather, turning it with a cork-screw motion. The worms will follow, and others will be loosened by sneezing. This repeat once more, but not oftener. In nine cases out of ten, the cure is immediate.

Currants—as standards or trees. This does not seem to suit our climate. They require some shade and bushiness to encourage moisture.

Boston Centre Draught Plow, Prouty and Mears.—This plow, it is said, by the aid of a wheel and a new arrangement of the gearing, a late invention of the patentees, carries a furrow ten inches deep and twelve inches wide, and turning it over with the greatest ease and facility, and leaving not a vestige of the sod to TELL. It requires no holder or guide, farther than to set it into the land, and turn it out at the end; and this can be done to perfection by a boy of eleven years of age.

Decay of Fruit Trees in Charlestown, Muss.—This seems to have been going much in the same way this season, as in the neighborhood of Cincinnati, and elsewhere in the West. There is soon to be an explanation of this matter, it seems, by competent individuals, both here and at the East.

Compost Manure.—Until the earth can be brought to give something for nothing, we may not despair of reaping benefit from the well mixing and stirring up of stable manure with earth, and other proper materials for the compost heap.

Charcoal.—This mixed with loam, is still growing in favor with agriculturists. It is the most astonishing article to make use of for all purposes of cultivation; and especially for plants under artificial treatment, says an eminent horticulturist.

From the Boston Cultivator.

RECLAIMING WET LANDS.

MESSRS. EDITORS—Mr. John Chamberlain, of this town, has reclaimed about three acres of wet land, and as the beautiful smooth field now forms a fine contrast with the once ugly looking swamp, that seemed like a nuisance on the farm, I will give an account of his management, hoping his good success in improvement will encourage others to do likewise, and now is a favorable time for the business.

Drains were made around the margin, and a large one through the centre. The centre drain was made very wide with slanting sides, on which a good crop of grass is produced; and this mode of making drains Mr. Chamberlain most approves of; and many others who have made these slanting drains prefer them to deep perpendicular ditches.

The hassocks were levelled by cutting them up with a bog hoe, and then they were piled up and burnt. Then gravel was hauled on about six inches deep, and compost applied, about 20 or 25 loads to the acre. The ashes were spread on with the manure, and grass seed raked in. He commenced about three years ago, and finished last year. It is now all in fine English mowing, and the best grass on the farm, producing two tons to the acre the first crop, besides the rowen. He manures with a little compost annually. The cost of reclaiming was from 50 to 60 dollars per acre, and Mr. C. now values it at more than $100 per acre. Before it was reclaimed, it was of no profit. E. C. FLAGG.

Southborough, August, 1844.

From the Tuscaloosa Monitor.

WOOL-GROWING IN ALABAMA.

On a former occasion, we alluded to the barren and hilly parts of Alabama, to some extent, unfit for any other use, as affording fine sheep walks, that might be made exceedingly profitable in the growth of wool. We are glad that an experiment is now making, as the letter of Messrs. Harris & Clayton will show. These gentlemen, both known to us as upright and industrious men, (and good practical printers withal,) have invested capital in a flock of sheep, of various bloods, which they keep some eighteen or twenty miles north of this city, having brought them from Tennessee last spring This is the first attempt, so far as we have been informed, that has been made upon a liberal scale, with proper attention, for the production of wool as a business, in Alabama. That the increase of the flock will pay a better dividend than almost any other investment, we have very little doubt.

The samples alluded to in the letter may be seen at our office, where several gentlemen have already examined and admired them.

As an enterprise, wool-growing in the South has been comparatively untried. It is estimated that forty millions of dollars are annually paid by this country for foreign wool, a great part of which sum might be kept at home by extending the production in parts of the United States where it can be successful. Whether Southern qualities will be equal to those of the North, we are not prepared to say; but wool fit for staple manufactures can assuredly be grown here, as we trust the experiment of Messrs. Harris & Clayton will demonstrate.

The following is their letter:

TUSKALOOSA COUNTY, Aug. 25, 1844.

MAJOR MILLER—Dear Sir: Enclosed we send you a few samples of our wool, both short and long. We are now shearing our flock, and shall have near five hundred fleeces, though we do not intend clipping our ewes this fall. We hardly know whether these are as fine samples as we could send you, but we think they will form an average at any rate. These samples are all from lambs, except the Bakewell buck. He is in his second year, and cost us five dollars. The Bakewell lamb's wool is, I think, seven inches: please straighten it and measure, and give its length.* It was dropped in February. No. 7 is from a half-blood merino lamb, dropped in February, and his fleece, when we clipped it, weighed full three lbs. See how thick it grew. But just look at No. 1, 2 and 3: they would grace Prince Albert's own back, in the form of a coat. These samples are at the inspection of the public.

Very respectfully,
Your obedient servants,
HARRIS & CLAYTON.

*Full seven inches by actual measurement.

From the Central New York Farmer.

WORK FOR SEPTEMBER.

Although considerable work is expected to be done this month, still it is not so pressing as the last, but the provident farmer will always go ahead of his labors, and thus preserve the mastery of the manifold operations of his farm, as by the pursuit of such a course, he not only renders his business a source of pleasure, but one of profit.

Plowing.—Flush up the ground you intend to appropriate to small grain, and be sure to plow well and deep, and to lay the furrow nearly flat, if the ground turned down be a sward. Do not take too wide a slice, nor suffer balks to occur, as they are not only injurious to your soil, but lessen its production.

Wheat.—This crop, although not cultivated to any great extent in this vicinity, is considered, in some sections, the most important crop to which the farmer can direct his attention; it is at the same time, one of the most difficult to cultivate with uniform success. Different, and even opposite causes, must be pursued under different circumstances, in order to obtain the same desirable results, a good crop; difference of soil—difference of climate—difference in the time of sowing—and difference in the variety of seed. This last we found verified this season, as the bald wheat was nearly all destroyed by the worm, while the bearded escaped, or at least was very little affected by the insect. Material variations are frequently required in the mode of culture, which renders the business of raising wheat one of the most complex of all the branches of agricultural practice.

Soil and Preparation.—In preparing the soil for many other crops, it is rare that much caution or skill is necessary; for instance, corn requires high manuring, and a rich soil, and it is scarcely possible to carry this to excess. But with wheat, the case is otherwise; land naturally rich, or highly manured, is apt to cause, during the hot season of summer, a too rapid growth of stem, at the expense of the seed; and rust, lodging, and ultimate failure is frequently the consequence. This evil, we have found, is caused to a far greater degree if strong unfermented manure is applied, which causes a still more luxuriant growth of straw. It is an established law in vegetable economy, that an extraordinary growth of the straw and leaves is always at the expense of the fruit and seed. Therefore, unfermented or fresh manure should never be applied to land intended immediately for wheat. It is best, when practicable, to apply fresh manure to other crops which are to precede wheat. In this way the manure becomes well rotted and thoroughly incorporated with the soil by the time the wheat is sown upon it. Land may be highly fertilized by this course, without any bad effects; indeed, some of the best crops are obtained from ground enriched in this manner—instances of which may be often seen in places where large quantities of manure have been deposited, demolished buildings, &c., where grain is often three times more productive than on adjoining ground in the same field.

When the above course of manuring is pursued, land is rarely made too rich for wheat, provided it is accompanied with deep plowing. This is indeed highly important in fertile soils. Nearly all who raise large crops on such soils, have made use of deep plowing in previous years. There are, however, some very shallow soils, where the subsoil will not admit of this practice; such of course must form exceptions.

It is now generally conceded, we believe, that *rest* is of no use to land and can never improve its quality while nothing grows upon it.—Ground which is not employed in producing food for animals, should be occupied in preparing food for plants; or, in other words, instead of lying naked, it should be producing some suitable crop to serve as a coat of manure to enrich itself.

Peas, beans and clover, are among the best crops to precede wheat, as they are very different in their nature from it, and consequently afford a greater change in the succession. Clover, in particular, possesses several advantages; its roots loosen the soil, furnish excellent manure when plowed under, and unlike the natural grasses, does not form so tough a sod as to require summer fallowing in order to break and pulverize it.

A neighbor turned over a tough green sward last year, which had been pastured for two years, and after giving it a thorough harrowing, sowed his wheat early in September, from which he obtained a good crop at a very small expense.

Corn for Fodder.—The usual time for topping corn has arrived. We are of the opinion that very early cutting the top stalks is unfavorable to corn. Whether the enhanced value of the stalks counterbalances the injury to the corn, is not so well settled. Our opinion is not only against early topping, but against topping at all. We prefer to let the corn stand untopped until the grain is glazed, and then cut it at the bottom, and set it up in small stooks to dry. Care, however, must be taken not to put it away until the grain is perfectly dried; and the same precaution is necessary with regard to stalks intended for winter food for cattle. We have no fears from storms, fogs or frosts, after the corn is once stooked. We do not assert that these cannot injure it then; but we have for years followed this plan, and our corn has escaped all harm from these causes. We have never had it injured, unless the stooks have been prostrated by violent winds. Fears may be entertained, that in this situation the corn will mould. But our experience teaches us otherwise. We have had it in this situation, through successive days in warm weather, and no injury suffered. Here it is secured against frost, against birds, and mostly against the dirt, which autumn rains throw upon the leaves and husks. Let it remain in stook, until it is well dried—from three to five, or six weeks, according to the state of the weather. Large stalks stand in stook much better than small ones. The larger the corn, the better it is suited to this process of curing.

Rye.—Your rye should be put in during this month, and the sooner it is sown, the better chance it will have to resist the frosts, and of not being winter killed. Sandy or gravelly soils, are best suited to its growth, and though many affirm that it does not require that the land should be manured, we have no doubt ourself that a moderate portion of manure well rotted, of ashes or lime, would have a very salutary effect. Whatever ground it may be put upon, every possible pains should be taken to have it in fine tilth. If it be not well pulverized, it will assuredly not thrive as well as might be desired.

When sown on stubble, a good crop may be raised by once plowing, if well done, by which the weeds and stubble should all be turned under; after which, the ground should be made free on the top, with a light harrow. By sowing early, good pasture for calves and young sheep is secured, after the common grass have failed; and even in the spring it may be fed down with small stock, without injury to the crop. Another advantage of early sowing is, the roots become much firmer fixed in the ground, and are not so apt to be flung out of the ground by the frost; besides, when sown early, less seed will answer for the same ground As in the common course of farming, there is more or less land upon farms which are in good condition to produce rye, that would not produce wheat, and from which a crop of rye may be raised with as little expense: we therefore recommend to farmers to sow rye, and be careful about the quality sown, as there are two or three varieties of this, which are in common use amongst us: one kind is lighter in color than the others, and commonly called white rye; this is to be preferred, as it produces equally as well as the darker kinds, and when well ground, makes a very wholesome and palatable bread, which is preferred by many people to wheat; for mixing with corn-meal for making bread, it is allowed to be superior.

Timothy.—Now is a good time to put in timothy and red-top seed. The ground should be well manured, and brought to a fine tilth. If you desire to cut it next summer, sow it alone; if that be not your object, you may put it in with your wheat or rye. In the spring, a top dressing of a compost, composed of ten bushels of ashes, and one of lime or plaster of Paris, would be found of great utility. The quantity of seed per acre, is from 12 to 16 quarts.

Rye Grass.—If you sow now, you may graze upon it next season, without injuring it. Two bushels of seed to the acre should be sown. The ground should be prepared as for any other of the grasses.

Pilfering.—This is a season when the owners of orchards, gardens, &c., especially in the neighborhood of thick settled towns and villages, are greatly annoyed by the depredations of boys, thieves, trespassers, &c. A strange notion seems to prevail among many persons on this subject. They do not regard the taking of fruit, vegetables or melons, as *stealing*. They consider it as a kind of venial offence, rather implying smartness, than criminality. It is high time that this notion was exploded, and that those who plunder orchards, gardens, and melon patches, were taught that they are as guilty of stealing, as though they took the owner's money, horse or other property. It is not generally known that the revised statues of the State of New York, declare the robbing of orchards, gardens, &c., to be a misdemeanor, and punishable by fine, and imprisonment, or both, in the discretion of the court.

This reminds me of a circumstance which happened when I was a little fellow, just old enough to be mischievous. I was beset by a parcel of my companions, to go and pilfer the parson's pears. The tree was large, hung full, and they were of a most delicious flavor.

Whether I was afraid of detection, and a flogging—whether respect for the parson, (for in those days children were brought up to respect the pious,) prevented me; or whether I was deterred by the recollection of my bad luck in pilfering melons, I cannot remember—but I told them decidedly, I would have nothing to do with the matter, and did all in my power to dissuade them from their enterprise.

I don't know how, but so it happened, that my honesty got to the parson's ears, and on Saturday afternoon, I received an invitation to go and see him. Away I went, conscious that I had done nothing amiss: how light beats the heart of innocence! The good man met me at the door; and taking me by the hand, said, "I have heard that you refused to join in pilfering my pears. Now, I mean to convince you that '*honesty is the best policy.*' Here," added he, placing a large basket of the finest fruit before me, "eat what you please, and take as many with you as you can carry." I felt that moment happier than Napoleon with empires at his feet. And the circumstance led me to remark, in early life, the consequence of an adherence to the maxim.

B.

From the Central New York Farmer.

HORN DISTEMPER OR HOLLOW HORN.

This disease, sometimes called, likewise, the horn-ail, is often fatal from unskilful treatment, It often makes its attack very suddenly, and may be known by the drooping of the head, lopping of the ears, a glassy appearance of the eye, lashing the sides with the tail, bloating of the chest, loss of appetite, &c.

Treatment.—Bleed from the neck, and cut off the end of the tail, if it is soft and loose. Prepare a solution of salt in vinegar, and make it strong with pepper, and pour it into each ear at the temperature of blood heat: this may be repeated twice in the 24 hours as long as the symptoms require. Put a table-spoon full of spirits of turpentine into the cavity on the top of the head a few times. Give two balls of tar rolled with meal, of the size of a butternut, twice a day.

The above method of treating this disease, is recommended by Mr. Samuel W. Bartlett, late of East Windsor, Ct., as having been very successful in a large number of cases treated by himself, and others in that vicinity.

WEDNESDAY, SEPTEMBER 18, 1844.

PREPARING COTTON FOR MARKET.--Our excellent friend and correspondent, A. McDonald, of Eufaula, Ala., has favored us with his mode of preparing cotton for market, the importance of which we cannot press too earnestly upon the consideration of cotton planters. For we are well satisfied, from our observation of the sales of cotton in this city, that no labor bestowed on cotton is better rewarded than that of putting it up neatly. Purchasers always look well to the order in which it is when offered, and their bids are regulated accordingly. If in good order, they offer what they believe its value--but if in bad, they of course make a sufficient deduction from the price, to remunerate them for putting it in good order.

No idea is more erroneous than that which is entertained by many farmers, that any bagging will answer, if it be strong enough to get it to the first market. They should recollect that it has to be much handled before getting it to its final destination, either in America or Europe; consequently, unless the bagging be good, it will not be in a fit condition to be exposed to sale on its arrival, until a considerable additional expense be incurred. All these things are taken into consideration by the cotton dealer, who purchases of the planter, and the price of his cotton is regulated accordingly. A difference, therefore, of a few cents more in the yard of bagging, is but a trifling increase on each bale, while it not unfrequently affects the value of the cotton ¼ cent per pound.

Let the cotton growers reflect upon these things, and be governed by them, and our word for it, their labor will be well rewarded.

SMUT IN WHEAT.--In our last number, we copied an article from the American Farmer on this subject, and to-day we have two communications as to the means of preventing this disease in the wheat crop: and as the season for sowing will soon be here, we commend them to the consideration of the reader. The plan adopted by Mr. Bell, to avoid smut, is entirely new to us; and, if it be a sure preventive, is certainly a great saving of labor, compared with the plan usually adopted of soaking in a brine or ley, and then rolling in ashes or lime.

We hope Mr. B. will favor us with the result of his experience in reference to the matter, --inform us how long he has practised this plan, and whether it has been always successful.

☞The editor of the London Agricultural Gazette, in an article relative to the frauds practiced upon farmers by the adulteration of manures—especially guano—says: "One would think, from the constant occurrence of these frauds, that farmers were not yet convinced of the expediency of the old rule—'*Taste and try, before you buy.*'" We should rather be excused (says the Boston Cultivator) from literally practicing this in the case of manures such as guano. We should prefer some one should "taste" for us.

GAPES IN CHICKENS.—The Southern Planter has the following from Mrs. E., a "gude housewife" and great chickenarian, in relation to this subject, which may prove beneficial to many throughout the country. This disease has, in almost every case, within our recollection, proved fatal to chickens. It strikes us that Mrs. E.'s mode of curing this disease is a good one, and we therefore recommend it to our fair country-women:

"Put the chickens in a covered basket, and hold the basket over a pretty strong tobacco smoke, and smoke them till they get *drunk enough* to cease crying. But avoid the error committed by a good lady, who followed the latter part of the prescription *too* literally. She waited till the chicks had ceased crying, but waited too long: they had died. Young turkies are benefitted by the same application."

SUBSTITUTE FOR SLAVE LABOR.—Mr. Bryant Cobb, of North Alabama, proposes to give up slave labor, and to offer suitable encouragement to induce good German farmers to settle about him, also some machinists and mechanics. He is located in a fertile valley, which is well watered; it is large enough for 15 or 20 farms; several saw-mills are in operation. He proposes to furnish farming implements and one year's provisions to industrious families, and let them farms on long leases, or make such other arrangements as may be thought mutually beneficial. Mr. Cobb's address is at Cobb's Store, North Alabama, about 15 miles Southeast of Huntsville. Latitude 32 50.

POTATOES.

We think it would be worth the while of some of our Southern farmers to make a trial of the suggestion contained in the article below, which we copy from the Buffalo (N. Y.) Commercial Advertiser, relative to raising potatoes from the *seed*, instead of the potato itself. Though it will take about three years to perfect the plant propagated in this way, yet, if it will ultimately improve this valuable article, is it not worth a trial? We believe the cultivation of the Northern potato, in this section of country, has not generally been very successful. Is it not possible that this plan would better adapt the potato so grown to our soil and climate? We are not aware that any one in this vicinity has tried the plan proposed, and we therefore make the suggestion to such as may have time or inclination to try it.

"If any of our readers have an opportunity to save potato balls or the seeds of this plant, we advise them to do so. The tops with the balls on can be hung up under a shed and dried, and kept ready for planting next spring. It is the opinion of several eminent agricultural writers, in Germany, Russia and Great Britain, that by continuous propagation from the tubers for many years, without recurring to the natural seed of the plant, it has lost much of its vigor and vital power. A late number of the Journal of the Royal Agricultural Society of England has a valuable paper, written by a Russian, on this subject, whose name we do not remember. The 'Dry Gangrene,' or a disease which may be designated by some other name, has affected for several years, the potato crop of Great Britain, Germany, Russia and Sweden. In each of these countries, and on the Hudson river in this State, and we know not how many other places, new seedlings have been propagated, which are said to be much superior to any old roots.

"The potato crop of the State of New York alone exceeds 30,000,000 bushels a year. We have the authority of Mr. Coleman for saying that in some parts of Germany they now contrive to raise 4,000 bushels potatoes on five acres of land, or 800 bushels per acre."

CURE FOR THE BITE OF A SPIDER.--We yesterday published a case of death, (says the Baltimore Sun,) resulting from the bite of a spider, which has induced a correspondent to send us a cure for similar cases. He says that the leaves of green plantain, mashed and applied to the wound, and the free drinking of strong tea made of the same herb, is an infallible and speedy remedy.

For the Southern Cultivator.

MR. EDITOR—I was much pleased with the suggestions of Liebig, jr., in a late number of the Southern Cultivator, on the subject of legislative aid to agriculture, by the establishment of a State Agricultural Society, and also a Professorship of Agricultural Chemistry, at the State University at Athens. The benefit and advantage other States have derived from legislative assistance, are incalculable, and will be felt and acknowledged by future generations. It will give a stimulus and energy to agriculture that will add to the wealth and resources of the State.

The reason that agricultural schools have so generally failed is, that they were not conducted on scientific principles. Physical labor, without science, becomes irksome to a young and active mind: so soon, however, as the mind becomes engaged and interested, the fatigue of the body will be unheeded. The plowshare opens to the view of the scientific farmer the richest treasures of geology and mineralogy. It is a cabinet that is inexhaustible and ever varying. And when chemistry unfolds the arcana of nature, and shows the different kinds of soils adapted to the production of each and every variety of vegetation, then agriculture becomes a science and the mind directs the physical labor to the greatest usefulness and advantage.

It is, then, the duty and the interest of the State, to place within the reach of her citizens the means of becoming scientific farmers. By establishing a Professorship of Agricultural Chemistry at her University, the young men then leaving the institution and returning home, would spread throughout the State, a science that would do more good to the community than all the Latin and Greek that could be crammed into their heads.

The true policy of the State requires the serious attention of her legislators to the consideration of these subjects. It is hoped, by one farmer, that the next legislature will make the necessary appropriations to carry into effect both the suggestions herein mentioned. PHILOS.

☞The first saw-mill in New England, and probably the first in this country, was built at Agamentico, (now York,) in Maine.

Corns.—One thickness of flannel confined over the corn, anointed twice a day with spirits of turpentine, will effect a cure. This is an important *discovery*. Wonder if the editor of the Connecticut Farmer's Gazette ever effected a cure with it: if he has not, he had better try it himself, before he recommends it to others.

From the Boston Cultivator.

MENDING A TREE.

We saw at Isaac Frost's, Newton, a tolerably large apple tree that had the bark eaten all around by the mice, some years ago, and of course would have died without some extra pains to save ti. Mr. Frost set about a dozen scions in the tree, one end in the green bark and wood below, and the other above the wound. They all took at both ends and grew well, excepting one which took only at the bottom and, is forming a little tree by itself The scions are now about two inches in diameter, and are touching each other. The tree is in a fine condition. This method of mending a tree is attended with some trouble, but by this simple means, which can be done in a few hours, a valuable tree may be saved, as has occasionally been the case.

Making Jelly.—Those who would make fine jelly, should always avoid boiling the juice of the fruit, when it is desirable to have the article, when made, retain the flavor of the fruit from which it was prepared. After the juice is pressed from the fruit, and the proper quantity of sugar added to it, let it be heated until the sugar is dissolved: after this is effected, no further heat is required.

A Curious Fact.- The following is the contents of a hawk's nest on a large pine tree, nearly one hundred feet from the ground, on the farm of Liberty Partridge, in Westminster, Mass. One black snake, 3½ feet in length; two large adders; two green snakes; one striped racer snake; five striped snakes; six chickens; five sparrows; one striped squirrel; two mice; one toad; one frog; two young hawks nearly half grown.

Agriculture.—What profession is more honorable, and more useful, than that of the tiller of the soil? The wisest men of the age have proclaimed farming one of the most humble, honorable and useful employments, that Providence has bestowed upon man—that is, scientific farming; for, a farmer without any knowledge of science, is not capable of cultivating an acre of land. Some farmers are too independent to get along well. I have actually seen farmers, (but not fit to be called farmers,) who would not only refuse to pay one or two dollars a year for an agricultural paper, but would expose their ignorance so far as to denounce them as containing nothing but falsehoods, manufactured by the editors, and their aristocratic correspondents, who pretend to be farmers, whose dishonest designs are merely to swindle the poor farmers out of a dollar or two, by their filthy papers. Such *farmers* as these ought to plow a hole deep enough to hide themselves, and be ashamed ever to be seen again on a farm.—J. J.

Leicester and Southdown Sheep.—The best breeders in England are now crossing these two breeds of sheep; but in general they do not breed from the cross. They keep the breeds pure, and kill the cross-bred stock. This is when raising for the butcher. A mixture of the Southdown does not make the Leicesters or Bakewells so fat as they are alone.

Plaster on Fruit Blossoms.—This will make them productive, when otherwise barren.

Solution of Lime.—This is destructive to slugs.

Tornado in Effingham County.—We understand that a destructive tornado passed over the upper part of Effingham county on Tuesday morning. The dwelling house of Mr. Hinely, near the Louisville road, together with all the out-buildings, except the kitchen, were blown down, and partitions of the window curtains of the house found at the distance of half a mile. Fortunately no person was injured. We did not learn the extent of the damage, but are informed that it was considerable.—*Sav. Republican.*

☞ We learn from a gentleman who left Fort Leaven on the 10th of last month, that preparations were then in progress among a body of about five hundred U. S. dragoons, to march Westward under the command of Major Clifton Wharton. The objects of the expedition are to endeavor to make peace between certain Indian tribes that have been a long time at war, to hold Councils with various tribes along the route, and to impress them with the necessity of preserving peace among each other. Also by the display of a considerable and well appointed force, to convince them of the ability of the United States to punish them for any aggressions committed upon our citizens, while in the Indian country. An artist is to accompany the expedition, to take sketches of the Indian Councils, games, &c. We also learn that the Dragoons are in fine condition, and fully prepared to act with efficiency. Major W. is one of the ablest officers of the army, and has been in command at Fort L. for some time.—*Phil. Inq.*

From the West.—The American Fur Company's boat Nimrod arrived here yesterday from Council Bluffs. She brings no news of much interest. The steamer Frolic was heard from, eight days ago, about 350 miles above the Bluffs, pursuing her way safely onwards to the Yellow Stone. A large number of the Company's men had deserted, or refused to do duty, and an express was brought down by the Nimrod for recruits. The Missouri river is becoming very low, and the sand bars and snags form considerable obstacles to navigation.—*St. Louis Rep., 29th ult.*

Terrible Explosion.—Our citizens were startled from their slumbers last night, about 12 o'clock, by a terrible noise, shaking of dwellings and rattling of windows, caused by an explosion of about 20 or 2200 lbs. of powder in one of the cylinder mills of the powder manufactory of the Messrs. Austins, about a mile from this village, demolishing the building and machinery and scattering portions of it for half a mile about. There was about 600 lbs. of copper balls in the mill, which are probably thrown to a considerable distance, but we have not learned that they have done any injury. We are happy to say that no lives were lost and no person injured. The cause of the explosion is unknown. The machinery was in operation at the time, but no one was in or about the mill. Loss $1,000. The accident will not prevent the supply of powder as usual.—*Akron (Ohio) Beacon.*

Astonishing effect of Electricity in curing hysterical lockjaw.—The following account of the efficacy of this astonishing remedy we should do wrong in withholding, though it should never again prove effective. We have the account from some friends, who chanced to be present, and saw the patient eating the first meal she had taken in five days a few minutes after the spasm had ceased. She had been previously nourished by drawing milk through the apertures of the closed teeth, through which the edge of a knife could be passed with the greatest difficulty. The young woman was thus affected in consequence of exposure to cold and fatigue and was completely recovered by the electro-galvanic apparatus applied to both angles of the jaw. The machine had not made forty revolutions, when the jaw opened to its full and natural width. We learn that it has been successfully applied for nervous diseases of the eye; also in a case of poisoning by laudanum, where two entire ounces had been swallowed. In this case the patient was revived by the machine, and collapsed alternately during five hours, the intervals becoming shorter till speech was re-established. Curvature of the spine has also yielded to its powers. Indeed, its proper application is as varied as diseases of general debility and irregular action.—*Journal of Commerce.*

BACON'S LARD LAMPS.—A new article, superior to all others for this purpose, emitting a good clear light without smell or smoke, and at an expense, counting Lard at 8 cents a pound, of about a quarter of a cent an hour.

These Lamps have been satisfactorily tested, and are recommended as "just the thing" for the use of planters, and all others who study utility, neatness and economy.

A supply of the above Lamps, with Fillers and Wicks for them. For sale by

HAVILAND, RISLEY & CO.

jy 24-d,c&Cultf

TURNEP SEED.

A SUPPLY of the following varieties of fresh TURNEP SEED just received, viz:

Yellow Sweedish or Ruta Baga, very fine for stock,

Large Globe Turnep, } Fine
" White Flat do. } for
" Hanover or White Ruta Baga do } table
" Norfolk do. } use.

For sale in quantities to suit purchasers, by

Aug. 30 18-tf WM. HAINES, Jr.

GARDEN AND FIELD SEED.

A GENERAL assortment of fresh and genuine GARDEN and FIELD SEED, among which are the following:

Red and White Clover,
Blue and Green Grass,
Rye and Orchard do.,
Timothy and Herds do.,
Millet and Lucerne do.,
Seed Corn of every valuable variety,
Seed Wheat,
Buckwheat and Potato Oats,

Kept constantly on hand by the subscriber, all of which are offered for sale at very moderate prices. All orders, by mail or otherwise, executed with neatness and despatch.

SOUTHERN CULTIVATOR.

VOL. II. AUGUSTA, GA., OCTOBER 2, 1844. No. 20.

ORIGINAL COMMUNICATIONS.

For the Southern Cultivator.

A HINT TO SEEDSMEN.

MR. EDITOR—The writer has been for several years in the habit of buying more or less garden seed, and frequently after taking much pains in preparing the ground, has been mortified at having no plants. The reason is plain: the seed were *over age*, and did not germinate. I propose, as a remedy, that friend Landreth, and other horticulturists, who prepare seed for market, be required, yes, *required*, on pain of forfeiting their customers, to mark the year in which the seed are grown upon their labels, in the place of "warranted fresh." Then, by a little attention to the time or age of vitality in seeds, (vide table, 2d vol. S. Cultivator, page 2,) the gardener might be saved the disappointment of the loss of time, seasons, labor, &c., saying nothing about the cost of seed. *Will dealers in seed* look to this matter a little? They might thereby do the country great service.

PUMPKINS.—This year I raised a very fine crop of pumpkins on a piece of poor corn land, (which had been improved a little before,) laid off for corn about 3½ by 4½ feet, and planted about the middle of April, in every ninth hill—i. e., every third hill in every third row, without any corn: about one peck of compost manure was used to the hill, well dug and mixed in and about the hill; old cotton seed were used in a few rows without any perceptible difference. The ground was, of course, worked mainly in view of the corn crop, but the yield was very handsome, though I cannot tell the precise quantity, as they have been fed liberally to my stock for several weeks past, (since the squash vines failed,) leaving them still very thick in the field. The injury to the corn crop could not be more than the hills not planted. This plan succeeds much better for me than the one in the Southern Cultivator, (vol. 1, page 5,) which I partially tried last year.

SEED CORN.—This is the time to select your seed-corn. Go into your best corn-field, select the largest ears from the most prolific stalks, and when well dried put the ears by till planting time.

ROTATION OF CROPS.—I have read a great deal about proper rotation, &c., and would like to see something more specific on the subject. I would be thankful, if some of your experienced correspondents would give their views, founded on experience, as to the best course of rotation for a man who does not make cotton, and works level land, poor enough and rather sandy. How would corn, peas and wheat, or oats do? and how should they follow each other—and the reason why?

ARTICHOKES AND PEAS.—Has any one tried these together? I think they would make a hog-pasture of the richest character, and do but little hurt to each other. The artichoke should girt every plantation by filling every corner of the fence, keeping out briars and bushes: thus planted, they will pay well for their room—they also present a handsome bordering for a field or plantation.

Yours, &c., GREENE B. HAYGOOD.

Casulon, Clarke county, Sept. 27, 1844.

For the Southern Cultivator.

MR. EDITOR—In the 16th No. of the Cultivator, I am glad to see that "Franklin" has again resumed the subject of "Overseers." I have not the pleasure of being acquainted with Franklin, but I am certain that he has handled that very interesting subject in a masterly manner, and in a manner which does not only reflect on him the honor of much practical skill in the art of husbandry—but, at the same time, such communications add intrinsic value to agricultural papers, which will be seen and appreciated by the wise and virtuous.

I agree with Franklin, who says: "My idea of a fine crop is first an increase of negroes," meaning a natural increase, as may be proved by his third interrogatory to an overseer. It is a remark made by travellers, both foreign and domestic, and has now a place in the records of our history, that the people of the Southern portion of the U. States are characterized by "liberality, kindness and hospitality." These are encomiums of no ordinary grade, bestowed upon us as a people, not by fawning sycophants, but by historians and philosophers, and whose jealousy of us has ever circumscribed such expressions in our favor to the narrowest possible limits. And while I endorse with pleasure the sentiments of "Franklin," I would urge the propriety for us, as a people, to continue to merit such laudations by universal benevolence, as well to our slaves as the "stranger within thy gates." It has recently been declared, by one of our Southern patriots, that "the slaves in the Southern States are the happiest peasantry on earth;" and, with such a system of management as that taught by Franklin, the above declaration will never suffer refutation.

Franklin propounds ten or twelve questions to an overseer applying for employment, the first of which is, "Will you obey orders implicitly, fully," &c. This question pre-supposes the proprietor is himself a practical planter; and here, perhaps, some would urge an objection, by stating that many persons own plantations who know nothing about planting: but here I take the liberty to say to all such as are unfortunate enough to own a plantation of negroes and land, destitute of a common knowledge of planting, either part with the property, or serve an apprenticeship by acting in the capacity of your own overseer. I also endorse the proposition of Franklin, when he says, "I appeal to the experience of all planters: during the recent hard times, has any single planter been brought to the block, (meaning his property,) unless for the security of debt, who made all or nearly all his articles of consumption within himself, though he made ever so small crops of cotton?" If agriculturists, throughout the whole country, would be governed by the maxim, "buy little and sell much," we should all do better; cold, hunger, hard times and tariff, would cease to annoy us.

D. B.

Houston county, Ga.

For the Southern Cultivator.

MR. EDITOR—The market for the present crop of cotton is now about to commence, and the price will mainly depend upon the quantity produced. Could the manufacturers know with certainty what will be near about the amount of bales produced in the United States, prices in our markets would be fair and remunerating, all things being considered. But while the buyer and manufacturer depend upon the vague and oftentimes spurious reports of A. B. and C., prices will be unstable—one day too high, and the next too low; first, to the serious injury of the planter, and in turn to the buyer. It appears to me that all these evils are within the reach of a remedy, and nothing could be more desirable, for uncertainty is a baneful check upon all kinds of business operations. The cotton planter, in conscience, asks no more from the buyer than fair and remunerating prices, and this is what the buyer is willing to give: but each party having made his calculation upon the probable amount of production, based upon wild and incorrect stories of partial travellers (being bad judges too) through the country, both parties are honestly deceived, and one or the other made to suffer loss. The remedy I would beg leave to propose, is to be found through your agricultural journal co-operating with all others within the cotton growing States, after the following manner:—In the first place, let the President of each Agricultural Society in each county in the State, and in all the cotton growing States, submit to the papers for publication, a report of the prospect and condition of the crop, with the probable number of bales likely to be produced. Counties destitute of regular organized Societies, can send their reports by the most intelligent subscribers to the paper. These reports, coming from the most intelligent planters of every county, could be relied on for veracity, and be condensed in a tabular form, and compared with the last year's production—each party, then, both planter and buyer, will be furnished with almost absolute data on which to act. By this means prices will be more firm, and security afforded against losses to both parties.

The cotton crop in Houston county, where I reside, was very likely until the last of August; heavy rains, and some remarkable cool days and nights, with a heavy wind, have altered the appearance very materially—and I venture the assertion that the present crop will fall short, in this county, of the crop of last year, from one-third to one-fourth.

SELECTIONS, EXTRACTS, &c.

EXTRACT FROM COLEMAN'S AGRICULTURAL REPORT.

In all parts of the country, women are more or less employed on the farms, and in some parts in large numbers. I have frequently counted thirty, fifty, and many more, in a field at a time, both in hoeing turneps and in harvesting. I have found them, likewise, engaged in various other services—in pulling weeds, in picking stones, in unloading and treading grain, in threshing machines, in digging potatoes, in pulling and topping turneps, in tending cattle, in loading out dung, and in carrying limestone and coal. Indeed, there is hardly any menial service to which they are not accustomed; and all notions of their sex seem out of the question whenever their labor is wanted or can be applied. The wages of women are commonly six-pence and eight-pence, and they seldom exceed ten-pence a day, excepting in harvest, when they are as high as a shilling. The hours of labor for the men are usually from six o'clock, a. m., to six, p. m., with an interval of an hour for breakfast and an hour for dinner. The women rarely come before 8 o'clock, and quit labor at 6, with the usual indulgence for dinner. Many of the laborers walk two and three miles to their work, and return at night. Their meals are taken in the fields, and in the most simple form. The dinner is often nothing more than bread.

In the season of harvest, immense numbers of Irish come over to assist in the labor, and this presents almost the only opportunity which they have, in the course of the year, of earning a little money to pay the rent of their cabins and potato patches. Nothing can exceed the destitution and squalidness in which they are seen—starved, ragged and dirty, beyond all description, with the tatters hanging about them like a few remaining feathers upon a plucked goose. At their first coming they are comparatively feeble and inefficient; but, after a week's comfortable feeding, they recover strength, increasing some pounds in weight, and, if they are allowed to perform their work by the piece, they accomplish a great deal.

I found, in one case, on two farms—which, though under two tenants, might be considered as a joint concern—more than four hundred laborers employed during the harvests, a large proportion of whom were women, but not exclusively Irish. The average wages paid the men in this case was one shilling sterling (or twenty-four cents) per day, and their food, which was estimated at about nine-pence (18 cents) per day. Their living consisted of oatmeal-porridge and a small quantity of sour milk or butter-milk for breakfast; a pound of wheaten bread, and a pint and a half of beer, at dinner; and at night, a supper resembling the breakfast, or two-pence in money in lieu of it. I was curious to know how so many people were lodged at night. In some cases they threw themselves down under the stacks, or upon some straw in the sheds, or out-buildings of the farm: but in the case to which I refer above, I was shown into the cattle-stalls and stables, the floors of which were littered with straw; and here the men's coats and the women's caps and bonnets upon the walls, indicated that it was occupied by both parties promiscuously. This was indeed the fact. Each person, as far as possible, was supplied with a blanket, and these were the whole support. I am unwilling to make any comments upon such facts as these. They speak for themselves: they are matters of general custom, and seem to excite no attention. I do not refer to them as matter of reproach to the employers, who were persons of respectable character and condition, and whose families were distinguished for their refinement. But it presents one among many instances in which habit and custom reconcile us to many things which would otherwise offend us; and lead us to view some practices, utterly unjustifiable in themselves, with a degree of complacency or indifference; and as unalterable, because they have been so long established. I believe there is only one part of the United States where anything resembling such a condition of things prevails, or would be permitted; and there only among a class of beings whose claims to humanity seem not very well established in all minds, and whose degradation, on account of their complexion, appears absolutely hopeless. But, even here, this indiscriminate consorting is not common; nor would it be permitted by any respectable planter.

This condition of things should certainly save this country from the reproach, if it be one, which some English tourists are disposed to attribute to American manners, that of treating the sex with too much courtesy and deference. I cannot bring myself, however, to view the subject with any lightness whatever. My confident conviction is that the virtue of a community depends on nothing more than on the character of the women. In proportion as they are improved, and treated with deference on account of their sex, women are brought to respect themselves, and the character of the men is directly improved: character itself becomes valuable to both parties. But in proportion as the condition of women is degraded, and they are considered and treated as mere animals, self-respect is not known among them, character is of no value, and the moral condition of such a class, or rather its improvement, is absolutely without a hope. Nor is it without its pernicious influences, which must be too obvious to require to be pointed out, upon the classes in the community above them. Much fault as some persons have been pleased to find with the deference paid to the sex in the United States, I should be very sorry to see it in the smallest measure abated. I do not believe, taken as a whole, there is a more virtuous population upon earth, than are the women of New England and the middle States; and nowhere is there a greater decency and propriety of conversation and manners. I speak of these portions of the country in particular, because with them I am intimately acquainted, and have a right to speak with confidence; but I have no reason to say that the same respectability of character does not prevail in other parts of the United States.

I do not claim for my country anything like an immaculate condition of society; very far from it: but I do claim for them a highly improved moral condition, and have no hesitation in saying, that in most of our country villages prostitution is unknown, and an illegitimate child is a comparatively rare occurrence. I add, with equal confidence, that under the influence of our free schools and universal education, and the disinterested and philanthropic exertions among all sects, for the religious education of the young in Sunday schools, the beneficial and ameliorating results fully equal every reasonable expectation. This comes of the value of character, and the lessons early inculcated upon them to respect themselves as women. I would, if possible, strengthen this sentiment; and therefore would, in no department of life, render less prominent the distinctive barriers between the sexes. In all my intercourse with society in the United States, and with opportunities as large as any man of observing all classes among them in the various conditions of life, I have never known an instance of a woman going to a public bar for drink, or sitting down in a public bar-room with men, or alone, to regale herself. The ale-houses and gin-shops in England are as much accustomed by women as by men, and the results of such practices are exactly what might be expected—an extreme vulgarity of manners, and a large amount of drunkenness among the lower class of women. What, as a matter of course, comes with it, need not be told; but the records of the police courts leave no one at a loss.

My observation in this case must be understood as applying solely to the lowest class; these constitute a very numerous portion. They apply, likewise, mainly to cities and large towns. In respect to the deportment of the middle and the highest class—with whom my intercourse, through their kindness, has been familiar and extensive—nothing in manners or conversation can be further removed from that which is vulgar or offensive; and for propriety and highest degree of refinement, nothing can be more exemplary and delightful.

In districts strictly agricultural, the low rate of wages does not admit of much expenditure in this way; and, if there are indulgences, they must be at home in the village ale-houses, and only occasional. For a considerable portion of the year, the farm laborers are not allowed any beer in the haying and harvesting: their allowance seldom exceeds one and a half pint, which, as it is small beer, cannot be considered excessive. I could not learn that any allowance of whiskey or spirit is ever given them by their employers, or that it is ever carried by them into the fields. The drinking, in this country, with the lower and laboring classes of people, seems, in a great degree, confined to the licensed houses, of which, certainly, there is nowhere any want.

In passing through the village of Glossop, in Derbyshire, a modern and an exceedingly well-built village, in a distance, I should judge, of less than three-fourths of a mile, I counted, as I passed along on the box of a coach, thirty-five licensed retail shops, most of which were probably for the sale, among other things, of intoxicating liquors. Indeed, the number of licensed retailers in every village in England is quite remarkable, and would seem, in many cases, to include almost every fourth house.

I am not disposed to object to the employment of women in some kinds of agricultural labor. The employment of them in indiscriminate labor is liable to the most serious objections. Nothing can be more animating, and, in its way, more beautiful, than on a fine clear day, when the golden and wavering harvest is ready for the sickle, to see, as I have several times seen, a party of more than a hundred women and girls entering the field, cutting the grain, or binding it up after the reapers. In cultivating turneps they are likewise extremely expert. In tedding and making hay, and in various other agricultural labors, they carry their end of the yoke even; but in loading out dung, and especially, as I have seen them, in carrying broken limestone in baskets on their heads, to be put into the kilns, and in bearing heavy loads of coal from the pits, I have felt that their strength was unnaturally taxed, and that, at least in these cases, they were quite out of "woman's sphere." I confess, likewise, that my gallantry has often been severely tried when I have seen them at the inns acting as hostlers, bringing out the horses and assisting in changing the coach team, while the coachmen went into the inn to try the strength of the ale.

As far as health is concerned, the outdoor employment of women is altogether favorable. As far as virtue or moral purity is concerned, outdoor employment in itself is not more objectionable than employment within doors. Indeed, from the inquiries which have been made into this matter, and the elaborate reports that have been given to the government, it does not appear that the agricultural districts, where the custom of out-door employment for women prevails, are more immoral than the manufacturing districts. But the natural effect of such employment upon women is to render them negligent of their persons, and squalid and dirty in their appearance; and with this neglect, of person, they cease to be treated with any deference by the other sex, and lose all respect for themselves, and then follow the invariable concomitants, mental and moral impurity, and degradation.

The working, likewise, promiscuously with men, which is done continually, must expose them to rude jests, and to language and manners which, among the lower class of men, are too often grossly indecent and immoral. In all other respects, many kinds of outdoor agricultural employment must be and is, as it is admitted, favorable to health and vigor. The general health and vigor of such women, so many hours engaged in reasonable exercise

in the open air, contrasts most favorably with the effeminacy, debility, and early decay of those who are confined in heated and close manufactories, or in sedentary employments within doors. Nor in point of moral conduct, as far as mere occupation is concerned, is there any reason to suppose that the agricultural classes would suffer in comparison with the manufacturing classes, or with the host of young women in cities, employed in various trades and in-door occupations. We have few instances, in the free States, of women being employed in field labor. The women in Wethersfield, Connecticut, have for years been accustomed to the cultivation of onions, doing everything for the crop, excepting plowing and manuring the land, even to preparing it for the market. They certainly have suffered no evil, but the contrary. Can men, dependent upon their own exertions for support, find wives better able to manage their household affairs, more frugal, more industrious, than the young women of Wethersfield? It must seem strange to many persons, if I also add, as I know I may with truth, that many of these young women are persons of good education, and to a degree, allowing for the retired condition of society in which they have been brought up, even of refined manners: so totally different, indeed, are the conditions of the laboring classes in England and the United States. In truth, no comparison can properly be instituted between them. In general, among the laboring classes in England, their low condition, their ignorance, and want of education, and the almost absolute impossibility of raising above the estate in which they are born, render them, to a great degree, reckless and improvident. Character becomes consequently of far less importance than it would otherwise be. There are wanting, consequently, the motives to that self-respect, which constitutes the highest security of virtue; and, under such a condition of things, it is not surprising to find a laxity of morals, which produces swarms of illegitimate children. This is attended by the usual consequence—an absence, on the part of the parents, of that sense of obligation to support and provide for their offspring, which is to be found in its purity and strength only in legal wedlock.

From the Plow Boy.

INDIVIDUALITY.

Friends, can you fail to notice, day by day, the great difference there exists between us members of the human family? Do you not observe the analogy, that as there are no two leaves precisely alike on the same tree, so there are no two individuals precisely alike in our common stock? We cannot account for this truth, but it is evident to all our senses. It seems surprising, then, that our fellow creatures, with this truth before them, should act in any other way toward each other than that of charity.

To illustrate it, let us take a plow for example, an implement which has called forth the genius of so many to improve. It is surprising what a number have been patented, and how frequently other new ones appear. If you go into Massachusetts, you will probably find them using a plow different in some particular to any you have ever seen before, and if you see the inventor of it, he will endeavor to show you the superiority of his plow over any other; but you go elsewhere and see other kinds of plows, whose inventors will each tell you that their plows are superior to any other. Which would you take among so many? Would you not get perplexed, and wish you had not seen them? or would you not have rather to consider the form and quality of the land you possessed, and judge for yourself which plow would best answer your purpose? Your decision proves your individuality. Each man knows best what will suit him; therefore, his plow to him is better than any other plow.

A man has invented a machine for brick-making, and from some of those who have adopted it, we are led to suppose that it is much superior to the old way, for that it performs much more and much better work. But other parties who have tried it, say that it is quite a failure, for altogether the machine is far more expensive than the old way, and produces very inferior work. Who is to decide, when one man tells you it is right, and another tells you it is wrong? Why, our own reason and judgment must reign paramount. We must use our individuality and decide for ourselves, because what may suit one man may not suit another.

So it is with diet; as the old saying goes, "what is one man's food is another man's poison." How common it is to hear persons say they could not live without tea and coffee, because, perhaps, they never tried to live without it. Those in the habit of drinking whiskey have said the same thing, yet the coffee drinker (not comprehending man's individuality or natural difference) condemns the whiskey drinker because he does not leave off his whiskey and live upon tea and coffee. Some persons, again, eat a great deal of meat, and say they could not exist without it—they should lose all their strength and not be able to perform their daily toil; without, at the same time, knowing that there are millions of human beings who have to perform their daily toil without ever tasting a bit of animal food, and such individuals no doubt would say that they could not exist if they gave up their vegetable diet and had to live on animal food.

Again—we must decide for ourselves which is best for us, by using our reason, and not condemn a man and call him a fool for destroying his constitution, because he drinks nothing but the pure water from the crystal spring.

Always bear this beautiful guiding principle foremost in your mind—THAT YOU MAY BE WRONG; but also exercise the reason God has given you to ascertain what is right or wrong for yourself.

Suppose you see your neighbor plowing his fields and planting his corn in some way different from you: he may, for instance, be trying some new mode which he has learned through studying an agricultural paper, or by his reasoning ascertained some facts in relation to the soil. Pray, then, throw aside the narrow prejudice and the short-sighted feeling which would pour forth its notes in ridicule. Wait patiently till you see the result, and if it proves successful, why you are, in common with many more, much benefitted thereby; and, if it should turn out a failure, you are likewise benefitted, for you feel the more satisfied that your own course is the best to pursue, and you are indebted to the individual who ventured beyond the common path for the sake of an investigation which might have benefitted all mankind.

Remember public opinion, which is the great governing power in our land, is not always right, for very often the brave spirits who step aside or beyond it, are those to whom we are indebted for some of the greatest blessings we now enjoy. If we were always to abide by public opinion, we should still continue plodding to the old church, on the old road, and putting our corn-meal across our horse's back with a lot of stones on the other side to balance it. But this will not do: if we want to progress, we must use our own intellects. We must examine all things and hold fast that which we consider good, without regard to the ignorant prejudices of (unfortunately) too many of our brethren. Bear in mind that it is not alone for self that we attain a new eminence, but for all those who choose to follow in our footsteps. But if we allow ourselves to be bound by public opinion to do as our fathers have done before us, we shall indeed have mill-stones round our necks, going on, or rather standing still, with our rude log cabins and our corn bread and pork. "Well," some of you may say, (to prove your difference of opinion,) "we are very well contented with all that." "So be it," I would answer, you enjoy that; but we will endeavor to go a little further, by using all our energies to build a better house wherein we can be free from many troublesome insects which we now have, and where we can enjoy a little more health and comfort. We would plant some fruit trees around our house, make us a tidy garden for domestic vegetables, adorned a little with some sweet-scented flowers to add a little more to our happiness; but our principal attention would be devoted to our fields, endeavoring to remedy deficiencies in the soil by applying the requisite manures and so on. If you differ from us, why well and good; you may go on in your old path and enjoy your corn and pork in contentment—though we cannot leave you this time, without saying a few words more to remind you of the prejudices which mankind, and especially those in power, have had to anything new or anything differing from the present. Remember Galileo who, for proving that the earth went round the sun, stood in such danger of his life. remember the prejudice and opposition Fulton had to contend with before he astonished the world by the power of steam: remember, also, the opposition manifested at the Revolution, as to the practicability of a republican government. Yet, every day the more demonstrates its glorious advance.

If you please, use your reason on our short essay and decide for yourself. Though we are so different, there is no doubt but it is for a good purpose, and that we are naturally so, we ought ever to bear in mind throughout all our wordly dealings.

A very celebrated writer said he fully and conscientiously believed that it was the will of the Almighty that there should be diversity of opinions among us, as it affords a larger field for our Christian kindness.

From the New Genesee Farmer.

COMFREY.

Prickly Comfrey.—[*Symphytum officinale.*] *If all is true* that has of late been published respecting this plant, it promises to become a very important acquisition to our agricultural products, not only as food for cattle, but for man. It was first noticed as an agricultural plant in Loudon's Gardener's Magazine, in 1830, by D. Grant, of Lewisham; where it was tried by a number of cultivators. Cattle of every kind are said to be fond of it: and Mr. Grant thinks an acre might be made to produce thirty tons of green fodder in one year. The plant is of easy propagation by seeds or roots; it is also of great durability, and if once established, would probably continue to produce crops for many years; and in that point of view, it would seem to be a valuable plant for the cottager who keeps a cow. In the spring of last year, there appeared in the Keene Sentinel a letter from the Rev. E. Rich, of Troy, New Hampshire, recommending the cultivation of comfrey for its foliage as fodder for stock, and for its roots as an article of diet for man. He observes, "it will probably yet prove one of the best and cheapest articles of healthful diet now known; not outdone by the potato or Indian corn!" He then details some experiments in the preparation and use of the roots as food, by drying and grinding, then boiling as porridge, &c.; and says he found it very beneficial for colds and other diseases of the lungs and bowels. He advises mixing one-third of comfrey meal with wheat or Indian, for porridge, puddings, griddle-cakes, &c. Should the taste, at first, be in any degree unpleasant as is often the case with new things, any agreeable condiments can be added. The letter further states, that the roots are to be dug once in two years, and that they will yield at the rate of more than two thousand bushels per acre; (!) and the two cuttings of the tops in one season, gave at the rate of six tons of hay per acre.

In an article on this subject in the Portsmouth Journal, last November, the editor, after alluding to the letter of Mr. Rich, states that Mr. A. Robinson, of that town, planted a bed of comfrey in his garden, last spring, half a rod square, the plants set in rows fifteen inches distant. They scarcely started till July, and the season was very dry; but on cutting the plants in September, the product, when dried, was 22½ pounds. He has no doubt but that next season, when the roots become well set, the bed will yield, at least, two cuttings of twenty-five pounds each; or at the rate of about 8 tons per acre. Mr

Robinson says his stock of all descriptions eat it freely; and he thinks this plant will prove a valuable acquisition to our agriculture.

Comfrey is called a native of Siberia, but it may be regarded as indigenous to this country. It belongs to the order *Boraginæ*, which consists of plants not remarkable for useful or nutritious qualities.

The plants can be found in almost every neighborhood, and it will be an easy matter to try experiments with it.

SOUTH CAROLINA STATE AGRICULTURAL SOCIETY.

GREENVILLE C. H., Sept. 10, 1844.

The State Agricultural Society met at Greenville, as ordered by the meeting in December last. The President called the meeting to order, when the delegates and members enrolled themselves.

The Society being now organized, Col. R. F. W. Allston introduced the following resolution:

"That the resolution passed in November, 1840, requiring the payment of an 'entrance fee' on the part of competitors for the Premiums of the Society, not being members, be, and the same is hereby annulled; and that the Premiums of this Society shall hereafter be held open to the present competition."

This motion was discussed by Mr. Allston, Col. Brooks, Dr. Gibbes, Mr. McBee, and Gen. Thompson, and was finally adopted, with the following amendment, proposed by General Thompson:

"That the Premiums of the Society shall be free to all members, either of the State or Local Societies—all others shall pay one dollar for the privilege of competing for said Premiums."

Mr. Roper then introduced the following resolutions:

Resolved, That a combined system of Agriculture, Manufactures and Commerce, are essential in promoting the prosperity and happiness of a community.

Resolved, That the large extent of country opened and preparing for the culture of cotton, in the Western and Southern States, and the superior adaptation of the soil to that culture, and other motives, render it important for the farmers of South Carolina to resort to a more varied means of promoting their individual and the general welfare.

Resolved, That, to accomplish this purpose, we recommend a system of household manufactures in every article where domestic skill can be made available. We recommend the raising of our own flour, bacon and stock, with an abundant grain, root, and hay crop, for the purpose of sustaining them, together with provisions and supplies of all kinds.

Resolved, That a scientific mode of culture, with the application of manures, which in all civilized countries have become objects of national direction, will greatly advance our prosperity: and that a memorial be sent from this Society to the Legislature, praying a continuance of the system of Agricultural and Geological Survey, till the whole State be scientifically explored, and the domestic resources of the country fully developed. And further, we recommend to all farmers the advantage of consulting the Agricultural and Geological Surveyor as to the nature of their soils, and best means of increasing their fertility and adaptation to raising a greater variety of products, than are at present cultivated.

These resolutions were discussed by Mr. Roper, Gen. Thompson, Dr. Gibbes, Hon. J. R. Poinsett and Major Perry, and adopted; and the following Committee appointed to petition the Legislature accordingly, viz: R. W. Roper, Dr. Gibbes, and V. McBee.

[Col. Allston then introduced resolutions proposing some alterations of the Constitution of the Society, which were adopted, but for the want of room, we omit them. Ed. Mountaineer.]

On motion, it was agreed the Exhibition should take place at 10 o'clock on to-morrow, and the Oration at 1 o'clock.

The following are appointed as the Committees to make the awards:—

On Horses.—O. B. Irvine of Greenville, R. F. W. Allston of All Saints, E. C. Leitner of Spartanburg, Paul Hamilton of Pendleton, A. G. Verdier of St. Lukes, B. H. Wilson of All Saints, Isadore Lartigue of St. Peters, Thomas Henderson of Newberry.

On Cattle.—J. R. Poinsett of All Saints, Jas. B. Davis of Columbia, Whitfield Brooks of Edgefield, Wm. Summer of Newberry, G. R McCullough of Abbeville, J. B. O'Neall of Newberry.

On Mules.—R. W. Gibbes of Columbia, Henry Parr of Fairfield, B. Stratham of Greenville, Wm. Walker of Spartanburg, R. W. Roper of Charleston.

On Hogs.—George Seaborn of Pendleton, J. Glenn of Newberry, V. McBee of Greenville, S. M. Earle of Greenville, Geo. Nicholls of Spartanburg, S. M. Wilson of Pendleton.

On Sheep.—B. Dunlam of Greenville, John Rivers of St. Andrews, B. F. Perry of Greenville, Rev. Mr. Potter of Pendleton, Samuel Clark of Edgefield, James A. Black of York, M. Subet of Newberry.

WEDNESDAY, Sept. 11.

The Society met at 10 o'clock, and the meeting being organized by the President, the Secretary read the proceedings of the 10th.

The Hon. J. B. O'Neall introduced the following resolution, which was unanimously adopted:

Resolved, That the President of the State Agricultural Society be requested to present to Mr. Edmund Ruffin, late Agricultural Surveyor of the State, the thanks of this Society, for the able and efficient discharge of his duty.

Col Brooks, of Edgefield, introduced the following:

Resolved, That the Agricultural Societies of Greenville, Pendleton and Spartanburg, be respectfully requested to reply to the following queries at the next meeting of this Society in Columbia, on the 4th Monday in November:

1st. What is the nature and kind of soils in your respective Districts? What are the principal products? What modes of cultivation are in use?

2d. What are the usual rotations of crops in practice? What manures are in use, and in what way applied, whether broadcast, in checks or drill?

3d. What agricultural implements are in general use? What kind are used in seeding small grain—what in the preparation of land, and what in the cultivation of corn and cotton?

4th. What are the favorite breeds of Horses, Cattle, Sheep and Swine—and how is the District supplied with these domestic animals? How are they wintered, and what grasses are used for hay?

5th. What fruits are cultivated, and what is the condition of the Horticulture of the District?

6th. Are there any dairy and grazing farms in the District, where cheese and butter are made for market?

7th. What effect is produced upon the Agriculture of the District by the practice of leasing land upon shares, and what agricultural changes are necessary to advance the prosperity of the District?

8th. Are root crops for stock cultivated? If not, be pleased to state the cause.

9th. State the average annual crops of cotton in each District, and the probable average per acre.

10th. If there be any manufactures in your District, communicate the number and kind, the number of hands employed in each, the quantity of the raw material used in the cotton factories, and especially the profits of each establishment of whatever kind, and such other information as it may be convenient to furnish, or important to the Society.

11th. Is there Marl or Lime in your District? If so, is it used for agricultural purposes, and what is the cost per bushel to the farmer?

These resolutions were advocated by the mover, and agreed to.

Col. R. F. W. Allston's proposed amendments to the Constitution were now called up, separately put, and agreed to by the constitutional majority.

A Silken Flag, manufactured by the Misses Flemming, of Spartanburg, and painted by a native Artist, (Mr. Wm. K. Barclay, of Columbia,) lately presented to the 36th Regiment, was exhibited to the Society.

Two specimens of colored and figured Silk, manufactured by Mrs. Dantzler, of Spartanburg, were exhibited. Mrs. Belcher presented a Straw Bonnet and Hat, made by herself.

On motion of Hon. J. B. O'Neall, it was unanimously agreed that the thanks of this Society be tendered to each of these ladies, for the skill, taste and elegance of their several specimens, and to Mr. Barclay, for his skill as an Artist.

Mrs. Poinsett presented, through the Hon. J. R. Poinsett, to the Society, some baskets of Grapes, grown in her garden; which, on motion, a Committee was nominated, of *venerable bachelors*, consisting of Messrs. Dunham, Stone and Goodlett, to hand around for distribution to the ladies in the gallery, and return thanks to Mrs. Poinsett.

Dr. R. W. Gibbes brought the attention of the Society to a Resolution, adopted some time since by the State Agricultural Society, to sustain an Agricultural paper, proposed to be issued by Mr. Morgan, Publisher of the Temperance Advocate, in Columbia. He stated the necessity of this paper, its remarkable cheapness, and the advantages likely to result from its support.

Mr. Smith, of Laurens, exhibited a Plow, called a *Labor-saving Plow*, and the following Committee were appointed to examine its advantages: Chancellor Johnson, B. Statham, Col. Glenn, W. Brooks and B. Duncan, and the Charman, reported favorably of it.

The Committee having examined minutely all the Stock, which was highly encouraging to the Society, were now ready, and being called upon, reported their awards as follows:

The Committee on Horses beg leave to report, that the exhibition of Horses was highly creditable and gratifying, giving promise of extensive and material improvement in the Stock of this section of the State.

Your Committee award the premium for the best Stallion over five years old, for Saddle purposes, to J T. Whitefield, of Anderson, for his bay horse, by Bertrand, dam Blackburn's Whip, (bred by himself.)

For the best Stallion under 5 years old, to Samuel M. Earle: for his yearling, by Monarch, dam by Nullifier, (bred by himself.)

For the best Mare or Filly under 5 years old, to Gen. Thompson's Chesnut Mare, 4 years old, by John Bascomb, dam by Red Gauntlett, (bred by himself.)

Your Committee particularly recommend Mr. Leverett's Filly, Fanny Elsler, as an animal next to that taking the award.

O. B. IRVINE, Chairman.

The Committee on Cattle, having examined the many fine animals submitted to their inspection, have unanimously agreed to the following awards:

The premium for the best Bull, over 1 year old, to Dr. C. B. Stone, of Greenville, for his Durham, bred by himself. At the same time, the Committee are of opinion a Bull exhibited by Mr. Moore, of Greenville, deserves a favorable notice.

The premium for the best Bull under 1 year old, to Col. E. C. Leitner, of Spartanburg, for a Durham, bred by himself.

For the best Milch Cow, to V. McBee, for a native cow, bred by himself.

For the best Heifer, under 1 year old, to S. M. Earle, for a Durham, bred by Col. Hampton.

J. R. POINSETT, Chairman.

The Committee on Mules, respectfully report, that they have considered the merits of the Mules offered for premiums, and have unani-

mously awarded it to Maj. Elias Earle, jr., of Greenville, for his Mule, 1 year and 4 months old. R. W. GIBBES, Chairman.

The Committee on Hogs, respectfully report, that they have diligently examined a very large number of various breeds of hogs, and most highly creditable to any country.

For the best Boar, over 1 year old, they award to Maj. J. M. A. Turpin, of Greenville, for a Berkshire and Lancashire cross—not without a most favorable notice of a strong competitor in a Berkshire, the property of the Hon. J. R. Poinsett.

For the best Sow, over 1 year old, to Dr. C. B. Stone, of Greenville, for his Berkshire.

For the best Boar, under 1 year old, to Dr. A. B. Crook, of Greenville, for his Berkshire.

For the best Sow, under 1 year old, to Col. D. Hoke, of Greenville, for his Berkshire.

GEO. SEABORN, Chairman.

The Committee on Sheep make the following Report:

They have examined three pens of Sheep, belonging to Dr. Crook, S. M. Earle and Mr. Stone. Whilst they would recommend most favorably all exhibited, they award as follows:

For the best Ram, to Dr. Crook—Bakewell and Southdown, (bred by Col. Hampton.)

For the best Ewe, to S. M. Earle—Bakewell, (bred by Col. Hampton.)

B. DUNHAM, Chairman.

These Reports were severally received, and the President made the distribution.

Hon. J. B. O'Neall was now called upon, and made his Address. And, on motion of General Thompson, the Society returned him thanks for its ability, and requested its publication, which was so agreed.

On motion of the Hon. J. B. O'Neall, Hon. J. R. Poinsett was requested to take the Chair of the President, and Col. Brooks introduced the following resolution.

Resolved, That the thanks of this Society be returned to the President for his ability and impartiality in the discharge of his duties; and to the Secretary, for his diligence in the discharge of his labors.

The President, on resuming the Chair, responded to this compliment with much feeling, and took his seat. The Secretary added, "that he would only say, no occupation in his life afforded him so much pleasure as the discharge of his duties as Secretary."

On motion of Hon. J. B. O'Neall:

Resolved, That the thanks of this Society be tendered to Mr. Smith, for his "Labor-saving Plow," and that it be recommended to the favorable notice of the farmers.

Dr. Gibbes moved that the thanks of the Society be returned to the Methodist Church, for the use of their building.

JAMES B. DAVIS, Rec. Sec.

THE FARMER'S FIRST LESSON IN CHYMISTRY.—A class has been formed at a place down in Hampshire (Punch does not feel called upon to speak more explicitly) for the study of agricultural chymistry. The plan for instruction is catechetical. The following lesson is founded on the responses, as reported to Punch by his own correspondent, delivered at one of its recent meetings. Mistakes, they say, afford often a valuable lesson. If so, it is hoped that the lesson subjoined will be of great value:

"Chymistry is keepun' a doctor's shop. An atom is a mossel o' zummut; a bit o' dust or zand, loike. The weight of an atom is the heft on un. Light is accordun as it med be: daylight, moon-light, or candle-light. Heat is that are as comes out o' the vire."

To the question, "What are the phenomena of heat?" the reply was, "Dooan't 'zactly know what you manes, zur. The effect of heat is, rooastun' mate, bilin' taters; burnin' yer vingers if you gets too close to 't. Lightnin' is a thunderbolt fallin' out o' the clouds; a thunderbolt is a thing like a clinker. An acid is any zort o' zour stuff, like vinegar or varius. An alkali is a foreigneerun' name var zummit or other, may be for a pig. Potash is ashes from under a pot. Soda is stuff as washerwomen uses. Ammonia is one o' them fine names as yer gentlefolks gives their darters. If you puts zulphuric acid to lime, and makes zulphate o' lime, why, of coorse, if you adds it to wuts, (oats) you gets zulphate o' wuts. A zimple body means a zimpleton, like Zilly Billy at the poorus. The laws of chymical union is like the laws of any other Union, pretty strictish, and o' coorse every chymical union has got a beadle. Chymical affinity, attraction, cohesion, composition, decomposition, analysis, synthesis, is a parcel of outlandish gibberish. Justus Liebig is zome Vrenchman."

The foregoing statements, we imagine, exhibit some slight discrepancy with the views of Faraday; but as the agricultural mind expands, its ideas of chymical science will very likely become rather more accurate.—*Punch.*

STEAM PLOWS.—A manufacturer in Cincinnati, has forwarded to St. Louis a plow that is to be driven by steam, for turning up the prairies of Illinois.

WAGES OF FARM LABORERS IN ENGLAND.

The wages (per year) paid in the county of Northumberland, as given by several gentlemen familiar with the subject, to the parliamentary committee, are as follows:

First Example.

36 bushels of oats,
24 " barley,
12 " peas,
3 " wheat,
3 " rye,
36 to 40 bushels potatoes,
A cow's keep for a year,
Cottage and garden,
Coals from the pit,
£4 in cash.

Second Example.

10 bushels of wheat,
30 " oats,
10 " barley,
10 " rye,
10 " peas,
A cow's keep for a year,
800 yards of land for potatoes,
Cottage and garden,
Coal,
£3 10s. in cash,
2 bush. barley in lieu of hens.

Third Example.

36 bushels of oats,
24 " barley,
11 " peas,
6 " wheat,
1000 yards of land for potatoes,
A cow's keep,
House and garden,
Coal,
£5 in cash.

The Scotch laborers seemed to me, from a very limited observation, strongly attached to their employers. On one farm, where I had the pleasure of visiting, one of the laborers had been in the employ of the same family forty years, and another sixty; to each of whom, although their labor now was of little value, the farmer continued the same rate of wages which they had in early life. This, indeed, would seem to be no more than just, that the honest laborer, whose life had been spent in the service of another man, should not be turned adrift in his old age; but, alas! how rare is justice!

The condition of the laborers in this country is a subject of such deep concern to the community, on the ground of pecuniary profit, as well as philanthropy and justice, that I shall again revert to it. The common wages of farm labor, vary for men, from five shillings to twelve shillings per week; but I think a fair average would be eight to nine shillings sterling. A shilling may be reckoned at twenty-four cents, so that the monthly wages for a man may be put down at eight dollars and sixty-four cents. This is the whole, where labor is paid for in money, excepting as a matter of kindness, the farmer generally brings the coals for his laborer. I am not yet able to speak of the condition of things in Scotland, but it is constantly boasted that the education of the Scotch laborer is always provided for, and that, in point of instruction, they are far superior to the English. This remains for me to see.—*Colman's First Report on European Agriculture.*

From the New Genesee Farmer.

WHEAT CULTURE.

Wheatland Farming.

The following article, by our esteemed friend, Wm. Garbutt, of Wheatland, we are sure will be read with interest and profit by many of our readers, and will prove of more value to some than many times the cost of this paper for a year. Mr. Garbutt, as is well known, is one of the oldest and best practical farmers in the purely wheat region of Western New York. His style of writing is peculiarly characteristic, evincing deep thought, as well as great practical experience. He is more used to wielding the plow than the pen, and depends more on his own observation and experience for guidance in his business, than on the theories and speculations of others; although he is not dogmatical, like many possessed of less knowledge, nor is he unwilling to be taught even through the columns of an agricultural paper. On the contrary, he has always been a warm friend of such publications—and, as past volumes of the Genesee Farmer will show, he has ever been willing to communicate the results of his experience, whenever he thought his brother farmers might be benefitted thereby.

The opinions set forth in the following article are entitled to the highest consideration, however widely they may differ from those of other intelligent farmers. Mr. Garbutt makes no claim to infallibility, however, and he does not wish or expect every farmer to adopt his opinions. His object is to elicit experiments and discussion, and induce other farmers to give publicity to their opinions on questions relating to their profession.

We think we discover one or two slight mistakes in his article—particularly in reference to the manufacture of manure; but we pass the matter for the present, in hopes that some other experienced practitioners will send us their views on these subjects. B.

MR. BATEHAM—I am glad to find the discussion of the best method of raising wheat, and the most profitable system of farming, introduced into the Genesee Farmer. The interchange of views and opinions by practical farmers is the surest way to arrive at the truth, and believing it to be the duty of every one to contribute something to the general stock, I will take the liberty to give my views on the subject.

I differ from those who believe that plowing in clover and sowing the ground alternately with wheat, is the most profitable course of farming, or the best method of raising wheat. I consider pasturing the clover two seasons with sheep more profitable to the farmer, more enriching to the soil, and more beneficial to the wheat crop, than plowing it under. I will endeavor to give my reason for this opinion, and leave it for the cultivators of the soil, for the next ten years, to decide whether my views are correct.

It is well known to many farmers that dried vegetables, such as hay, straw and stalks, make more and much richer manure by being fed to animals, to say nothing of the profit of keeping the stock. But green vegetables, and particularly clover, are not much improved (as manure) by feeding, as they do not require the heat, moisture, nor the same amount of fermentation to prepare them for the food of plants and it is the economy of nature that nothing is lost; vegetables are the food for animals, and the breath and droppings of animals are the food of growing plants. But to my wheat growing.

Let us suppose that A. B. and C. have each 100 acres of good land, in equal condition for producing wheat, together with sufficient grass land for keeping the teams and other necessary

stock of the farm. Now, suppose A. divides his land into two equal fields of 50 acres each, and has one in wheat and the other in clover each year. The clover he plows under and sows with wheat annually, and he has 50 acres of wheat to harvest. If he pursue this course for ten years, his wheat crop, I believe, will not average over 20 bushels per acre—but call it 22 and it will be 1100 bushels; from which deduct 50 bushels for seed, and he will have 1050 bushels for market. Call this 6s. 6d. per bushel, which is as high as we can calculate for an average, and it will make $853.12 yearly income for A.

B. divides his land into three equal parts of 33⅓ acres each, one of which he has in wheat, the other two in clover each year. He also keeps 450 sheep; these he pastures on his fallow till it is plowed, instead of plowing in the clover as A. does. The third field he divides with a temporary fence, and takes 20 acres of it for hay, which, together with his chaff and straw, will be sufficient for his sheep; and the 13 acres not mown, together with the fall feed on the meadow and stubble, will afford ample pasture for the sheep after the fallow is plowed. B. having 16⅔ acres less wheat to sow and harvest, his expenses of labor will be very little more than A's. His sheep will make his hay and straw into excellent manure, which he must put on the 20 acres of mowed land, and this is to be his next year's fallow.

B's 33⅓ acres of wheat will average for ten years under the sheep system, 27 bushels per acre, or 900 bushels—from which take 33⅓ for seed, and he has 866⅔ for market; this, at the price before named, will give him $704.16 for wheat. His 150 sheep will yield in wool and increase of flock, $1.50 each, or $225 in all, making the whole amount of B's income $929.16.

C. divides his land into ten acre lots, with several of the division fences temporary, so as to be removed at pleasure. He will have annually 30 acres in wheat, 10 in barley, 10 hay, 20 pasture, and 10 in hoe crops, of which 2 acres should be potatoes, 3 wurtzels, and 5 corn. He will keep two hundred sheep, (which he can do, and keep them well,) and breeding sows sufficient to raise 20 hogs annually for market. The hogs and sheep will make all the stalks, hay, and straw into valuable manure, which will be much improved by feeding the sheep with wurtzels. The 3 acres of wurtzels, 5 of cornstalks, 10 of hay, and 40 of straw, will winter 200 sheep well; and the fallow, together with the after feed on the mowed ground and stable fields, and twenty acres of pasture, will be abundant for their summer keeping.

The 10 acres of mown land must be well manured and plowed in the fall, for the next spring's hoe crops; the 10 acres previously hoed must be plowed in the fall for barley; and as soon as possible after the barley is off, give a shallow plowing and thorough harrowing, so as to vegetate all the barley and other seeds on the surface, then give it a light dressing of well rotted manure, plow it well, and sow it with wheat. In this way, C's thirty acres of wheat will be, ten after barley, and twenty summer fallow, on which his sheep were pastured till plowed. The 20 on summer fallow, will average 30 bushels per acre for 10 years, owing to the increased quantity and the quality of manure he will annually apply; and the 10 after barley, will be as good as A's 22 bushels per acre—making the whole amount of wheat, deducting 30 bushels for seed, 790 bushels, worth, at the price stated, $641.89. Then the 10 acres of barley will average 40 bushels per acre; (this has been my average yield for ten years past,) deduct 20 bushels for seed, and the remainder, at 3s. 6d. per bushel, will be worth $166.63. The 3 acres of corn, highly manured, will yield 50 bushels per acre; deduct 1 for seed, and keep 30 to feed the sows and young pigs, and the remainder, at 3s. 6d. per bushel, will be $95.81.

The wurtzels feed to the sheep and hogs in winter; the two acres of potatoes, with the thirty bushels of corn, and the stubbles, &c., will keep the sows and twenty hogs raised for the market, until they are a year old, when they will average 200 lbs. each on foot, at 2½ cents per pound, which will be $100. The sheep, at $1.50 each, will be $300: the whole together making an income for C. of $1304.32. But he will have extra expenses in cultivating his land; he must employ three extra laborers—one for the year, at $120, and two for seven months, at $12 per month—$168: but these men will do each one month's work in harvesting and thrashing, which will be worth $18 per month. If we deduct this from their wages, it will leave $234, as the extra expense of cultivating C's land: deduct this from the proceeds, and his income will be $1070.32.

Each of these three farmers must use alike of plaster, say eight tons per year—five on their land and three on their manure in the yard. Their wheat must all be seeded each year with clover, and B. and C. must add three quarts of timothy per acre. But their expense in seeding will not be greater than A's, owing to his having more acres to seed. If B. and C. do their duty in making, saving and applying their manures, B's ground will improve, and his crops increase over A's, and C's over B's more than in the foregoing estimated proportions.

RECAPITULATION.

Yearly income of A from 100 acres is		$853 12
"	B "	929 16
"	C "	1070 32

Now, fellow cultivators, test this matter for yourselves, and let your experience settle the question. But *do not forget* that C. must pay particular attention to his stock and *manure*—especially the sheep in winter.

Wheatland, Aug., 1844. WM. GARBUTT.

From the Central New York Farmer.

FALL PLOWING.

MESSRS. EDITORS—Will you allow one, who has derived much instruction and pleasure from a perusal of your pages, to contribute his small share to the common stock of agricultural knowledge, by placing at your disposal a short communication on the subject of fall plowing. The season is now at hand when this work should be performed, and I beg leave to state some of the advantages which are, in my opinion, to be derived from it. One important advantage to be derived from fall plowing, is a more thorough and complete pulverization of the soil intended for spring crops, than could otherwise be obtained. This, on stiff soils, is of the first importance. The action of the frost during the cold season, has the effect to divide and pulverize the upturned furrows, and to separate the parts, so that in the spring a mellow tilth is found, which cannot fail to be beneficial to all crops we may desire to raise. Upon this point, I am not aware that there is any difference of opinion, and I only call attention to it here for the purpose of urging the advantages of fall plowing. And, as a means of facilitating this process of pulverization, the plan of lapping the furrow slice is undoubtedly to be preferred. To this, I am aware, many persons object, but to me it seems capable of the fullest demonstration, that as by lapping the furrow both the surface and the edge of the furrow slice are exposed to the action of the atmosphere, a more perfect pulverization must take place than when the flat surface only is exposed, which must be the case when the furrows are turned perfectly flat, as is frequently the case. There may be, and doubtless are, good reasons for flat plowing even in the fall, as on ground where the grass is tall and cannot otherwise be covered, and perhaps other causes. But these are only exceptions to the general rule. At other seasons of the year, and on dry or porous soils, it is doubtless proper, in many instances, to invert the soil so as to leave a smooth and even surface. But I have been led from the subject of fall plowing to a dissertation on the method of plowing generally. Another reason for fall plowing, although it may be considered only as consequent upon those before alluded to, is the fact, proved by the almost unanimous voice of farmers, that crops on fall plowed land are generally better than on land plowed solely in the spring. I have known excellent crops grown on ground which was plowed in autumn only, without any preparation in the spring further than a thorough harrowing, and so far as my information extends, has proved generally successful.

I desire, however, to mention one other argument in favor of fall plowing, which I regard equally important with those already mentioned. I refer to the great advantage of advancing the spring work by having, as far as possible, all the plowing done in the fall of the year. In those sections of country, where winter grain is not extensively grown, and where, consequently, the principal reliance must be on spring grain, the spring work is excessively fatiguing and laborious, especially for teams; and any method which will relieve this branch of farm labor, must be advantageous to the farmer's interest. It not unfrequently happens, too, that land intended for spring crops is so much saturated with water in spring as not to admit of plowing until just about the season for sowing or planting, so that when the land is to be plowed, the putting in of the crop must inevitably be delayed beyond the proper season. Add to this the consideration that all crops can be got in in better season, and all the operations of the farm performed in a more proper manner, when sufficient time is allowed, than when all the labor of plowing and putting in crops, fencing, &c., is crowded in the short space of two months, and we have, as I should think, sufficient reasons for practising fall plowing to a much greater extent than is now prevalent in this country.

I have now given you my views at sufficient length upon this subject, and will only add that if any of your readers hold to different principles from those I have advanced, they will confer a favor on your correspondent, and doubtless on the public also, by communicating them to you, where they will have a fair chance of becoming known to the community. I do not desire controversy, but shall be ready to discuss the subject with persons entertaining different views, provided the discussion can be properly conducted and with a view of arriving at correct results.

I have, however, written sufficient for my first communication, and will close by expressing the satisfaction which I have derived from agricultural reading, and urging upon farmers the propriety of sustaining agricultural journals.

August, 1844. PLOWMAN.

From the Central New York Farmer.

THE REAPER'S HARVEST SONG.

The light winds gambol among the flowers,
The clouds have rolled away,
And the mists have fled from the leaping streams
Before the coming day,
And the ripened grain on the fruitful plain
Invites us, "*sons of toil*,"
Now, with ready hands to gather in
The products of the soil.
For lo! 'tis the harvest time,
The blessed harvest time.

Away to the harvest field, away!
The sun wheels up the sky;
No bondsmen we, but untasked and free,
Our sickles keen we ply;
And the waving ranks of bearded grain
Fall prostrate on the field,
And grateful we bless the HAND that gives
Such full and ample yield.
For lo! 'tis the harvest time,
The blessed harvest time.

Work! work! for the day will soon be gone!
We may not linger now,
Each trusty steel ply with earnest zeal,
With bared and moist brow.
In faith we sowed, and with gladness reap
The bounties GOD has given;
And fondly trust when He binds his sheaves,
He will gather us in heaven:
At the coming harvest time,
His blessed harvest time! DE VERE.

Cassville, N. Y., August, 1844.

WEDNESDAY, OCTOBER 2, 1844.

☞Look at the swamp and meadow lands, (says an exchange paper,) with which our country abounds, that are now worthless, and causing sickness and death in their vicinity. All these might be reclaimed, and made the most productive land, by a small outlay of time and capital. The owners have neither because they have too much land already calling for their attention. The muck contained in these places, can be made to pay better interest than bank stock: yea, it properly used, it may be the farmer's mine of wealth."

☞A writer in the London Gardener's Chronicle, says he has entirely discarded the old mode of allowing cucumbers to run on the surface of the ground. He trains them to trellises, and finds that he has not half the trouble with them that is required by the old plan, and that the plants continue much longer in bearing, when so treated.

Coal Tar as a Paint.—This article, which is abundant and cheap, has long been used successfully as an economical paint, particularly for iron. A correspondent of the American Agriculturist says:—"I think it would be well to call the attention of farmers to the use of coal tar as a paint. The tar produced in coal gas-works is used extensively in England for painting fences, out-buildings, &c., and is being introduced in this country also. It never alters by exposure to the weather, and one or two good coats will last many years. It is the cheapest and best black paint that can be used. Our buildings are painted with it; all our apparatus also; and even the wrought-iron pipe we place in the ground is coated with it. I think if its advantages were fully known, it would be generally used throughout the United States. The Government soak the bricks used in building the Fort at Throg's Neck in this tar, which renders them impervious to water; and posts painted with it are protected from rot, when in the ground, as effectually as if they had been charred."

☞Last year, (says Dumfrie's Courier,) we stated that a gentleman of our acquaintance had planted beans in the same rows with potatoes. The result, we learn, exceeded his expectation, the produce being 36 bushels of beans and 12½ tons of potatoes per acre, both of excellent quality.

☞Two tea-spoons full of finely powdered charcoal, (says the N. Y. Herald,) drank in a half tumbler of water, will, in less than fifteen minutes, give relief to the sick headache, when caused, as in most cases it is, by superabundance of acid on the stomach.

Guano.—The Lancaster Guardian says: The most easy and simple method of detecting an adulteration in guano, and also ascertaining the quality of the article, is the following:—Take four pounds of guano, and add one quart of water for every one of guano; stir them well together, and let them stand for a few days; if the guano be good, it will float an egg or a potato, and if it floats well, add water in half pints until the egg or potato sinks to the bottom; and that guano which floats an egg with the greatest quantity of water is the best. If any earth or sand has been mixed with the guano, it will be found at the bottom of the vessel.

☞A correspondent of the Exeter News Letter gives the following reasons for early rising, which are conclusive. It is to be regretted, however, that, with many, fashion and idleness are of superior influence to sound reason. The writer says:—"The practice of early rising should be adopted—1st. Because nature does not require but a few hour's sleep. 2d. The morning air is the most healthy and invigorating to the system of any in the course of the day. 3d. The body and mind are better prepared for the necessary business of life in the early part of the day than any other. 4th. By avoiding the habit of sleeping in the morning, there are more hours of consciousness and activity, so that life is made to appear longer than it otherwise would."

☞Those who wish for neat bedsteads, (says the British American Cultivator,) should wash them well with boiling water, and then put quicksilver, beaten with the white of eggs, in every crack and corner. One white is enough for a bedstead, with as much quicksilver as it will receive. It is the only thing that will keep bugs away when the bedsteads cannot often be attended to. It is a certain poison to bugs.

Tomato Tart.—The New England Farmer says: Roll out your dough very thin, and place it on the plate in which you intend baking your tart, and slice your tomatoes very thin, spread them over the dough very thinly, take about two table spoonsful of brown sugar, and one of ground cinnamon bark; spread the two over the tomatoes, bake it well, and you have a fine tart.

☞The British American Cultivator says that the fumes of brimstone will remove fruit stains and iron-mould from linen and cotton. Moisten with cold water, then hold it over the smoke of the burning brimstone.

Large Pears.—We were presented (says the Southern Geo. Recorder) by a friend, a few days since, in DeKalb county, with a pear weighing within a few grains of 1¼ pounds. The same tree from which it was taken, we were informed, was full of others equally as large, if not larger. They are quite juicy and well tasted.

☞Two or three spoonsful of strong ley, made of oak ashes, and mixed with molasses, are recommended as a positive cure for croup.

☞A writer in the Michigan Farmer, recommends buttermilk for the destruction of lice on cattle.

From the Southwestern Farmer.

CURING PEA VINES.

Your correspondent, C. M., in calling the attention of your readers to the curing of the pea vines, deserves, at their hands, thanks. It is an important means of keeping stock, which, if well cured, will do better than any other species of forage we have. I have seen it cured for 20 years, and as the mode is different from his, I beg to give it to you, leaving to your choice to dispose of as will suit you. After you have either cut the vines near the ground, or pulled them up, leave them in a swath until they have wilted, not taking longer than half a day. Then, with forks, throw them up into hand-cocks, small at the base, and as high as will not press together, only by their own weight: after remaining thus for a couple of days, open out for an hour or two in sun and haul up. Having provided a rail pen with surplus rails, and boards to cover, then put rails in for floor a few inches above the ground, a foot or so apart, on which throw in some 2 or 3 feet thick the vine; put on another floor of rails, and fill again 2 or 3 feet: continue thus until the pen is 10 or 12 feet high and cover. Many persons fork in a layer of straw of any kind, oats, rye or wheat, with every layer of the vine; many use salt in both ways, and no question but what it is as saving in the end.

Now for the reason. If the vine is cured as "fodder or other hay," you will lose every leaf, much of the stem, and one entirely unacquainted with the vine, would lose nearly all—for they would let it remain until dry. Lucerne, clover and pea vine, require the same treatment, there being so much sap in the stalk that you would lose all the smaller part before the stems, or thick part, was cured—but by merely wilting, the leaf and leaf-stalk is retained in a degree, and by throwing into cocks, the air passes through: the moderate heating it receives has a tendency to ripen the juices, making sweeter for stock, and toughens the vine—and very little exposure will cool it off.

Some persons pull and put in pens as above, and the use of salt will protect: it may mould a little, but try the mouldy part to even a well-fed mule. Those who are saving to their land all they can, will not pull up the vine, but cut off with a grass knife, saying the tap root is a benefit, and ought not to be taken from the land. One thing I press on those who have no experience—rather run the risk of losing, by having put up too green than too dry. I have seen them in a house 14 by 18 and 12 feet high, when 2 to 3 feet from the wall they were very hot, yet stock ate them very greedily. I thought they were lost.

Saving Seeds.—"Like produces like," is a general law of nature; the same both in the vegetable and animal kingdom. If a cultivator, then, desires to have any production earlier than usual, let him procure the first seeds that ripen on a well grown and productive plant, and so proceed year after year, and he will obtain this desideratum.

Every variety of vegetable may be rendered more productive, by selecting every year the seed of the most productive and well-formed plants. For instance, peas that grow in long, full pods, on vines that bear abundantly; and if you would have them earlier, take those which ripen first; choose beans the same way; select the finest heads of grain for seed before reaping; select seed corn from stalks that bear two or more good ears, and take the largest and best formed ears. Choose from stalks that are large at the bottom and run off to a small top, not very high. For early onions, select seeds that ripen first, and have good form: turneps the same, and so on, following the same rule throughout. There is no work, attended with so little care, which is so much neglected by the farmer as this.—*Plow Boy.*

Go to Work.—There are thousands and tens of thousands of young men among us whose only resource against the accumulated miseries of

a destitute manhood, and a disgraceful old age, is the workshop or the farm. It is useless, at this day, for every young man to aspire to the lot of living by his wits, for it is a task in which few who undertake it have the talent requisite to ensure success. How many there are at present "loafing" away the precious years of youth in our cities and villages, who ought to be acquiring the rudiments of some honorable and useful trade. Learning is by no means incompatible with the practice of the arts; for, the more one "knows" the more likely will he be to succeed, and to do honor both to himself and the profession in which he is engaged.—*Plow Boy.*

From the New Haven Palladium.

The Halo or Solar Phenomenon.—The Rings around the sun yesterday (September 9th) for two hours before and after midday, appear to have been generally observed by our citizens with much interest, and to have awakened an intelligent curiosity to learn more respecting appearances of this kind, and their causes.

The present Halo was remarkable for its duration, and afforded favorable opportunities for observation. About mid-day, it consisted chiefly of two complete rings, one about 45 degress in breadth encircling the sun at its centre, and the other about 72 degrees broad, having its center in the zenith, while its circumference passed through the sun. The smaller circle was accompanied by an eclipse of the same major axis and of small eccentricity. Directly opposite to the sun, 36 degrees north of the zenith, the circumference of the larger circle was intersected by two other circles of nearly or quite the same diameter, forming, at the point of intersection, a bright spot, such as would naturally result from the combined light of the three luminous rings. The ring that encircled the Sun exhibited the colors of the rainbow, frequently with much vividness and beauty. The other rings were white, and fainter as they were more distant from the sun. Small portions of circles, however, with prismatic hues, appeared at different times both in the East and West.

On recurring to works that give an account of solar halos of past times, it will be seen that the majority of them correspond, in their general features, to this, having a circle and eclipse around the sun, a large circle with its circumference passing through the sun's center, and two other circles intersecting this at a point directly opposite the sun. Thus in the 7th and 10th volumes of the American Journal of Science, two halos are figured bearing all these characteristics. The circles, however, are sometimes still farther multiplied, and of dimensions varying from the present.

Such a uniformity of structure must depend on *some* law, which regulates the formation of halos; but the nature of this law is not fully developed, although its investigation has occupied the most eminent opticians, as Descartes, Newton, Huyghens, Mariotte, Young and Brewster. The cloud which forms the basis of the phenomenon, is always the same, both in the solar and lunar halos, consisting of a thin, gauze-like, milky vapor, called by meteorologists, *cirro-stratus.* It is known to be very high, falling within the region of perpetual congelation, the lower limits of which, in our latitude, are about two miles above the earth. The moisture deposited by these clouds, would be in the form of snow or particles of ice, and it is from the peculiar reflections caused by the bright surfaces of such crystals, that these phenomena are believed to be produced. Not much difficulty has been experienced in accounting for the production of the ring that encircles the sun, since its cause is somewhat similar to that which produces the rainbow; but to explain the origin of the ring which has its circumference in the sun's center, has been found much more difficult. The reflection of the sun's light from crystals of a cylindrical and prismatic form, has been supposed to furnish a clue to the explanation, although it has not always clearly appeared how this would produce the appearances in question.

From the Southern Agriculturist.

PARTICULARS OF THE EXPERIMENT OF MARLING

Mr. Editor—I noticed in the last number of your valuable journal, a communication headed, "Successful Marling," in relation to a field I had marled for the present crop of cotton, in which the writer expresses a desire to learn the particulars of this experiment. It affords me pleasure to give any information in my power on the subject, being fully satisfied myself, from a previous trial, of the great efficacy in the use of marl. I instituted this experiment to endeavor to put its beneficial effects beyond doubt, and to convince those who were yet sceptical of the inestimable value of this substance. Your author has been misinformed as regards the land which was marled being an *old field.*

The following were the particulars of the experiment:—Twenty-five acres of very light high land was cleared of its original growth, oak, hickory and pine, in the winter of 1842, and planted in cotton every year: in February last, the beds were levelled with the hoe, and the marl carted on, at the rate of 150 bushels to the acre, which was well pulverized, and strewed over the field as equally as possible—strength of marl 70 per cent. The land was bedded in March and planted on the 1st of April. Ten rows through the middle of the field were left without marl. The cotton crop has suffered very much from continued drought, the marled cotton much less so than any other. In the above experiment no manure was used. It was my intention to have had the cotton of this field kept separate, in order to test its relative production with that of my other fields, but during my absence from home, the cotton was mixed.

In 1843, a square of 105 feet was marled in the same field, at the rate of 100 bushels to the acre—marl 70 per cent. The beneficial effects were very evident, particularly in the early maturing of the fruit: a gentleman, who visited this field in the summer of 1843, was asked his opinion as regards the appearance of this square of cotton; he replied; that it was more luxuriant; that he saw very few blossoms compared with the other portion of the field: on examination it was discovered that *pods* had taken the place of the *blossoms*—showing evidently, that the marled square was at least ten days in advance of the other.

The bed of marl is about one mile from the field: when not interrupted, carted twelve loads a day—seven bushels a good load for two small mules, the road being very rough.

Yours, &c., John A. Ramsay.
Charleston, Sept, 17, 1844.

Fruit Trees.—Plant a few trees of the best kinds you can get; if not rich food for the palate, hogs will not refuse them. If you will listen to old saws you will never plant any; there will some be found who have not succeeded—they, of course, condemn the fruit, rather than their own management.—*Plow Boy.*

MR. AND MRS. CHAPMAN'S
BOARDING AND DAY SCHOOL.
No. 228 Broad-st., Augusta.

☞ THIS Institution has been under the direction of its present principals for six years, and the success which has attended it has enabled them greatly to increase the facilities it affords for the education of young ladies. Provision is made for thorough instruction in all the departments of female education from the elementary English studies to the higher branches of literature and science. The next term will commence Tuesday, October 1st. Pupils can enter at any time during the term, and will be charged for the time they are members of the school.

Tuition $8, $12 and $15 per quarter, according to the age and standing of the scholar. Music and French at the usual rates. Board $15 per month.

References.—Rev. C. S. Dodd, Rev. W. T. Brantley, Rev. G F. Pierce, Dr. W. H. Turpin, Mr. J. M. Adams, Mr. D. Hand, Augusta; Gov. Crawford, Milledgeville; Dr. E. E. Jones, Madison; Col. Wm. Jones. Warren; Dr. F. George, Jasper; Mr. W. B. Munro, Columbus.

BACON'S LARD LAMPS.—A new article, superior to all others for this purpose, emitting a good clear light without smell or smoke, and at an expense, counting Lard at 8 cents a pound, of about a quarter of a cent an hour.

These Lamps have been satisfactorily tested, and are recommended as "just the thing" for the use of planters. and all others who study utility, neatness and economy.

A supply of the above Lamps, with Fillers and Wicks for them. For sale by
HAVILAND, RISLEY & CO.
jy 24-d,c&Cultf

TURNEP SEED.

A SUPPLY of the following varieties of fresh TURNEP SEED just received, viz:

Yellow Sweedish or Ruta Baga, very fine for stock,
Large Globe Turnep, } Fine
" White Flat do. } for
" Hanover or White Ruta Baga do } table
" Norfolk do. } use.

For sale in quantities to suit purchasers, by
Aug. 30 18-tf WM. HAINES, Jr.

GARDEN AND FIELD SEED.

A GENERAL assortment of fresh and genuine GARDEN and FIELD SEED, among which are the following:

Red and White Clover,
Blue and Green Grass,
Rye and Orchard do.,
Timothy and Herds do.,
Millet and Lucerne do.,
Seed Corn of every valuable variety,
Seed Wheat,
Buckwheat and Potato Oats,

Kept constantly on hand by the subscriber, all of which are offered for sale at very moderate prices. All orders, by mail or otherwise, executed with neatness and despatch.

WM. HAINES, Jr.,
No. 232 Broad street, Augusta, Ga.

SELECTIONS, EXTRACTS, &c.

From the Farmers' Cabinet.

WORN-OUT LANDS.

In the American Farmer, of December 27th, appeared an extract from a communication by John Jones of Wheatland, to the Farmers' Cabinet, in which he makes allusion to the astonishing effects brought about in the renovation of worn-out lands in Delaware, by Dr. Noble, of Philadelphia. On land which cost but fifteen dollars per acre, and produced but five bushels of wheat three years ago, by the application of eight loads of manure, costing, freight included, less than one dollar and fifty cents per load, the Doctor has raised forty-seven bushels of wheat from *one* acre, and from the remainder rather less, the average being an enormous increase over the produce of former years. The Editor of the American Farmer expresses an "increase desire" to learn the secret by which the Doctor has been enabled, at the small expense of less than twelve dollars per acre, to effect such astonishing results.

We would inform him there is no secret whatever in the method pursued, but such as any farmer might discover for himself, if he would but take the trouble to read some of the numerous works upon the application of chemistry to agriculture, lately published. Knowing by chemical analysis or examiuation, the composition of the grain and straw of wheat, and that of the soil, it was an easy matter to apply those materials which were needed, in order to produce a healthy and vigorous growth. He prescribed for his wheat and soil as he would for a patient, and with equal success, health and strength have been restored to the suffering subject.

The Doctor formed a compost obtained from various sources, consisting of the refuse of tanners, soap boiling establishments, &c.; in short, of such animal and vegetable substances as contain soluble salts, or which can be made subservient to the growth of plants. In the selection of these substances he was guided by their composition, as made known by chemical analysis. "Give," says the rational agriculturist, "to one plant such substances as are necessary for its development, but spare those which are not requisite, for the production of *other* plants which require them."

"An empirical," or quack system "of agriculture, has administered the same kind of manures to all plants, or where a selection has been made, it has not been based upon a knowledge of their peculiar composition." The phosphate of soda or lime, the silicate of potash, and sulphate of ammonia, or other salts containing these in other combinations, are necessary for the production of wheat; these have been supplied by the Doctor, and why should we be astonished at the results which have followed their application? He has adopted the *scientific* method of manuring, and if his knowledge of the composition of the soil and wants of the crop was exact, and his conclusions correctly drawn, he could not err in the application of his manures. His is *indeed* a triumph of science over the old fashioned, uncertain, and empirical mode of farming; here is an example worthy the attention of every farmer, and especially should it be considered by those whom prejudice has so blinded that they cannot perceive the vast benefits arising from the judicious application of scientific knowledge to agriculture. It is indeed "creditable to the Doctor as a scientific farmer;" we hail him as a benefactor, and desire that he may persevere in that path of usefulness in which he has found both pleasure and profit. J. S. L.

Philadelphia, Second month, 6th, 1844.

LABOR-SAVING PLOUGH.

The Columbia (So. Ca.) Advocate says:—The following is a description of the Labor-saving Plough exhibited at Greenville, S. C. We also append certificates furnished by gentlemen who have tried the Plough, in order to satisfy the incredulous that it is no "humbug." Our readers are aware that it was highly approved by the committee appointed to investigate its advantages over other similar ploughs.

Labor-Saving Plough, or a new and improved model.—The subscriber has tested the utility of this Plough by six years experience. It is an improvement taken from a Plough first constructed by Mr. C. Garlington, and afterwards improved by Mr. Smith, and combines the following desirable qualities:

In the first place, its structure is such as to prevent the horse from injuring the corn or cotton with his feet. In cultivating hill sides the rear Plough fills up the furrow made by the one in front, which cannot be done so compactly with the single plough. On stony land from the operation of two plough shares and the increased weight, the work can be performed much better than with a single plough. In new land, the double plough does superior work after the land is broke with a coulter. It is not impeded by roots any oftener than the single plough. One round finishes a cotton row.

Mode of Planting.—After the land is broken up, I lay off with a single shovel plough, drop the corn, and then plough round it with the double plough which makes a beautiful ridge, a little the highest in the centre. After the corn is large enough for ploughing, plough round it with a shovel on the stock, the earth can be thrown from each side, so as to cover all the grass, and cotton can be made with less hoeing than the ordinary plough requires.

MITCHELL SMITH.

N. B. I can plough six acres in each day, the week round.

—

I have used the plough of Mr. MITCHELL SMITH, above described, and concur fully with the representations made by him. It is, in my judgment, the most valuable plough I have ever seen. In using it, I have worked a single horse, and have found it easily drawn with the ordinary shovel ploughs on the stock.

H. C. YOUNG.

—

LAURENS DISTRICT, S. C., Nov. 9th, 1842.

Dear Sir: I am highly pleased with the improvement that you have made in the construction of a tool that is of such vast importance in cultivating our soil. I commenced my crop with it and ended with it, and I am now able to say to you that I have gathered nearly as much more of corn and cotton to the hand, than I have ever done heretofore. I find the objections that I had, previous to using it, were groundless.—It requires no more strength to manage it than any other, it matters not what may be the situation of the ground; to say the least of it, I have no doubt but that in a few years you will see them used more than any other farming tool now in use. Yours with respect,

JNO. W. WALLACE.

CURE FOR FOUNDER.

The seeds of sunflower are the best remedy known for the cure of founder in horses. Immediately on discovering that your horse is foundered, mix about a pint of the whole seed in his feed, and it will give a perfect cure.—*Cultivator.*

SHELL-FISH AS MANURE.—Having noticed the good effects of shell-fish in gardens, applied to carrot and onion beds, it occurred to a gentleman of our acquaintance that the same species of manure would be found equally useful on a larger scale, in the case of a green crop cultivated in the open field. Accordingly, he instructed his laborer to repair to the shore, and excavate four cartloads of live shell-fish, composed chiefly of wilks, cockles, and muscles. When carried home the deposite was thrown into a heap, and allowed to remain until it began to emit an unpleasant odor. Warning thus given, the shells were smashed and mixed with peat earth, to absorb the moisture and facilitate the application. They were then laid in the drills, after the manner of bones, at the rate of 16 bushels per acre; sown with turnips; and, the better to test the utility of the experiment, turnips were planted the same day over thick layers of barnyard manure. The seed on the shells took a wonderful start, the plants showing themselves at the end of three days, notwithstanding the intense drought; while the dung operated so slowly, that eight days elapsed before the slightest tendency to greening appeared.

Thus far the shells and substance enclosed have worked perfect wonders, and bid fair to outvie crushed bones, and even guano. The carbonate of lime and animal matter in shell-fish are great nourishers of vegetable life.—*Dumfrie's Courier.*

PRUNING FRUIT TREES.

Hints on the system of Pruning Fruit Trees, as practiced in the London Horticultural Society's Garden.

As the raising and cultivation of fruit trees forms one of the principal objects of pursuit by a great mass of people in this enlightened country, I should be pleased to offer a few hints (if you should think them worth publishing) on a proper system of pruning, and a few first principles in connection with it, which may prove useful to some of your readers who are not thoroughly acquainted with that important operation—important, because on the performance of it, in a great measure, depends the health, vigor, and production of fruit. To have a true knowledge of it, it is necessary that the operator should be in some measure acquainted with the laws that govern vegetation, and know the functions the different parts have to perform; for, unless he does, how can he be sure of the consequences that are to follow; and it is no ways improbable that that which was intended for a service, may turn out an evil; hence it is obviously necessary that the operator should be acquainted with vegetable physiology, in order to insure success; quite as necessary as it is for the surgeon to know the functions of the human system, in order to perform a successful amputation.

I shall now endeavor, and at the same time hope, to satisfy your readers, by pointing out the principal thing that is necessary to be known, namely, the functions of the leaves. It is essential also to know that every part of a plant, from the minutest fibre to the ponderous stem, has its own useful office to perform; but as the development of all those parts entirely depends on the leaves, it is on that account I consider them the principal organs of the vegetable fabric.

The roots absorb moisture (containing the food of plants) by their extremities, and it is transmitted from them through the stem by means of channels, formed by nature for that purpose, to the leaves, where it undergoes a chemical process. The fluid, on entering, contains many different substances, owing to the particles of matter it meets with in its progress through the vessels of the alburnum. This fluid does not become the proper food until it is duly exposed to the sun's rays which act on the cuticle of the leaves, when that fluid that is superfluous passes off by evaporation, and that which is left becomes elaborated and prepared as the proper food, passing into the system, and depositing a new layer of wood to the outside of oxogenous, and to the inside of endogenous structures, passing on to the roots, always leaving something after it, that adds to the diameter of each part it passes through, and finally elongates the tips of the roots or forms new roots. The matter that does all this is prepared by the leaves, by which alone the great importance of them is clearly shown. It is an admitted fact that the greater the quantity of leaves over a given part, the more that part increases in diameter. The secretions for fruit are likewise prepared by the leaves, and deposited in the tissue for the ensuing year's fruit; hence the more leaves the more secretions for fruit will be formed. But this does not hold good in all cases; for instance, strong, rank leaves that hold or receive no proper juices, and leaves not fully exposed to the sun's rays, are of no use for the formation of secretions; therefore, if the leaves are not properly exposed to the sun's rays, digestion is prevented, and they become worse than useless. It is highly essential that the juices are prevented from being lost in the formation of useless wood.

The system I am going to describe, which is practised in the London Horticultural Society's garden, and first put into practice in England, by Mr. R. Thompson, the acknowledged leading pomologist of Europe, principally depends on summer management. It is as follows:

Allow the young shoots to grow until the leaves become too crowded; then cut off their growing points only. By this means you will stop their elongation and confine the juices to the already formed leaves, where they will become fully elaborated for the ensuing year's fruit, which would not occur so readily if left to the formation of useless wood; for, be it remembered, it requires the secretions properly prepared, by the action of the sun's rays, in order to produce fruit; this check will cause the shoots to throw out lateral branches, which must be stopped in the same manner, for the confinement of the juices, as already described.

This system of summer pruning will be found to be of the first importance in the production of fruit, and it requires but little trouble when properly attended to. Winter pruning is only a secondary object when compared to this system, and I hope it will be clearly seen, when the principles here laid down are properly investigated. All that is necessary in winter pruning is, to remove all useless and superfluous wood. For peaches, nectarines, and apricots, plenty of young wood is required, and the operator should be guided by the health and vigor of his trees, the soil and situation in which they grow; all these circumstances must be taken into consideration, to perform the operation aright. The system I have described will be found to answer the summer pruning of vines and fruit-bearing trees. B. CARMICHAEL.

Nonanton Hill, Newton, April, 1844.

From the American Farmer.

WORK FOR OCTOBER.

We have the second Fall month upon us, and with it brings its toils and its pleasures—while its toils consist in preparing the ground, and committing the seed to the earth, those toils are not without their pleasures, for they force the mind upon the anticipation of the profits which are to arise from them, and excite in it those pleasurable emotions which spring from the belief, of after ability to meet engagements and contribute to the wants and comforts of one's family—and such reflections as these to the man of warm and generous sympathies are beyond all price, for they serve to assure him in the hope, that those on whom his every affection rests will be well cared for, and that those with whom he may have pecuniary engagements, will have no cause to complain of confidence reposed. And now let us turn to the work which the season requires should be done, and that quickly,

ON THE FARM.

Wheat.—It is full time that every farmer should have his ground in a state of preparation to receive his seed wheat, and perhaps, it would be better that he had it already in the ground; for we must confess that, notwithstanding early sown wheat is subject to the *fall ravages* of the Hessian Fly, still, we would rather run the hazard of that enemy, destructive as it is, than that ample time should not be given to the plants to attain a sufficient strength of roots to resist the action of frosts. This is our opinion, and it is for our readers to exercise upon it their own better judgments.

Preparation of Seed Wheat.—To avoid smut it is always safest to subject the seed wheat to a soak previous to sowing. This soak may be either made of the ley of wood ashes—a brine of salt; or stale urine, either to be made strong enough to bear an egg, and after permitting the seed wheat to remain therein for twelve hours, it should be taken out, drained, and have a sufficient quantity of slaked lime mixed with it to cover or whiten each grain of wheat. The wheat should in every instance be sown immediately after being taken out of the soak and powdered with lime, as if it remains long exposed after being thus prepared, it is apt to suffer in its germinating powers. We prefer, except upon a close lay or grass-sward, to plough the seed in 3 or 4 inches, then to harrow and roll. The rolling brings the earth in immediate contact with the seed, promotes early vegetation, ensures a much better stand of plants, and prevents washing.

The following recipe for a soak for seed wheat, has come very opportunely to hand, and we give it a place here. As the *initials* will show, it comes from an individual, who, besides being the great *pioneer* in Agricultural improvement in this country, has been its constant, untiring and enlightened friend for near a quarter of a century—and who has richly earned the name of Agricultural benefactor.

TO PREVENT SMUT IN WHEAT.

To the Editor of the American Farmer:

I always read with especial interest your own remarks and advice to your patrons as to the "WORK" to be done at particular seasons. In your 4th of August number, to which, (having been for some weeks absent) I have just looked back, you recommend, as you have well and repeatedly done before, that wheat should be *steeped* before it is sowed—can there be any doubt that every grain would be better for it, —steeps well prepared, of good ingredients, serve to kill the eggs of insects, to throw off the unsound grain, and as a *manure* for that which is to be committed to the earth. I lately read of one to *prevent smut in wheat*, which my informer, Mr. Dechest of Tennessee, said he knew to be *infallible* after very many experiments. You may not have published it,—it is this: Dissolve a pound of *blue stone* in as much water as will cover five bushels of wheat, and let it remain therein about 18 hours before it is sowed, and, as he says (allowing me to use his name) you will never have smut in your wheat.

I. S. S.

Quantity of Seed per Acre.—Less than two bushels per acre should not be sown, as a smaller quantity than that will not sufficiently cover the earth, to exclude those pests of the wheat field, weeds and grass, and very certain are we, that full seeding tends to increase the product.

Finishing the Seeding.—No wheat grower should consider his seeding finished until he shall have run water furrows through and around his field, to carry off the rains of winter and keep the plants dry.

Rye.—If there be any who may not have got in his Rye, there is still time, provided *no time is lost*, and he plow in his seed some three or four inches, and harrow and roll it well.

Quantity of Seed per Acre.—From 4 to 5 pecks per acre is the right quantity—but as the season is late we should prefer the latter, as it will allow some loss from winter killing.

Fall Plowing.—All stiff clayey grounds will be the better of fall and winter ploughing, provided that work be done in good weather, when the earth is not *wet*. To plow clays in that state is always injurious, as they become little better than mortar, and seldom can be got into good condition during a season; but if plowed when in good condition in the fall or winter, the best effects are derived from the exposure to the frost.

Hogs for fattening.—These should be penned early, as they take on fat much faster in moderately warm weather than in cold, and consequently consume less corn. They should be given charcoal, ashes, rotten wood and salt while being fattened; and it is important that regularity should be observed with regard to the times of feeding and watering.

To save corn, cooked pumpkins serve an excellent purpose in the commencement of fattening.

Cattle Stabling and Shedding.—All cattle should have dry quarters during winter, and if you have not stabling or shedding to afford it, let us advise you to put them up, as the saving in feed will more than compensate for the cost in a very few years, besides the satisfaction it will afford you, to know that your stock is secure from the winter's rains, sleet and snows.

Pumpkins.—Gather these before they are injured by the frost, and stow them away in some dry place, taking care not to pack them but a few rows high, and not to put any unsound ones among those which are sound.

Fences.—Examine all on your place, and repair such as need it.

Orchard.—Gather your fruit by hand as soon as ready. Be careful to do it in dry weather, and put them away carefully. Your trees may be pruned of dead limbs; but the wound must be cut smooth and covered with a mixture of equal parts of fresh cow dung and clay, taking care to cover the application with a thick cloth to keep out rain. The trunks of the trees should be painted with a mixture of soft soap and flour of sulphur, in the proportion of a gallon of soft soap to 1 lb. of sulphur.

Draining.—Your wet ground should be drained during the fall months.

Buckwheat.—This grain should be cut before it is nipped by the frost, as its straw is good feed for your cattle.

Work Cattle of all kinds must receive additional attention during this month and the next, as it should be an object with you to carry them into the winter in good condition.

Potatoes and Turnips.—These roots should be gathered before they are frosted. Let them be taken up in dry weather and securely stowed away where they will not be liable to become frozen.

Beets, Parsnips and Carrots.—See to the digging and putting away of these roots.

Cow Yard.—Before you bring your cattle in for winter let your yard be spread a foot deep with mould and leaves from the woods, and so spread as that the centre will be lower than the sides—all the materials you throw into it, will,

by the spring, be converted into first rate manure.

Sheep.—See that these animals have shelter through the winter.

We have thus travelled through the list of such duties as are most urgent of attention on the farm, and shall conclude our monthly task, by wishing you good markets for your present year's crop—good crops and good prices next year, and that health, happiness and prosperity may abound with you and yours.

From the Western Farmer and Gardener.

HINTS TO WOOL-GROWERS.

We confess our anxiety to see the growing of wool prosecuted in this country to a large extent, and with eminent success. To do this, our farmers must study the construction, organic structure, and habits of sheep, and the alike simple and increasing laws of nature, which govern the transformation of certain elements contained in the food of this valuable animal, into wool upon its back.

Both the quality and quantity of this product, as well as the health and vigor of the animal, depend, in an eminent degree, upon the constituent elements which enter into the composition of its food. If these be but poorly adapted to the formation of muscle, fat and wool, the animal must be poor, its fleece light, and its progeny more or less degenerated. On the contrary, if its food abound in the raw materials which go to make up these animal products, being merely changed into new forms and combinations by the action of vital organs, then such products will be abundant.

All concede the importance of a knowledge of the workings of his iron and woollen machinery to the manufacturer of broadcloth. All appreciate the necessity of his understanding the nature of wool, how to cleanse it by chemical agents, and both the art and science of making beautiful and fast colors.

We contend that the wool-grower who elaborates the great staple of the manufacturer of woollen goods, should in like manner understand what elements of the soil, air and water enter into the composition of these cultivated plants, which his living machinery can best transform into wool. He should also understand the operation of this machinery, which can be largely varied in its results, by changing the circumstances which affect it, and the raw material to be operated upon.

We have some twenty millions of sheep now in the United States, which elaborate for their owners not far from fifty millions pounds of wool per annum, or about two and a half pounds on an average per head. If we allow this annual clip to be worth as high as thirty cents per pound, then the fleeces will bring an average of seventy-five cents a piece. Allow that sixty-five cents per head, and the lambs will pay the whole expenses of their keeping, the nett profit is ten cents on each sheep. If by any means we can enable this wool-farming machine to elaborate only the two hundred and sixty-fifth part of a pound of wool MORE in each twenty-four hours than it now does, this will give an average fleece of three and a half pounds instead of two and a half, which at thirty cents a pound, will increase the profit on each sheep from ten to forty cents, or FOUR HUNDRED PER CENT!

This important gain to our farmers we believe to be practicable. To realise it, requires no additional outlay of labor or capital. It requires only a little more practical knowledge of the operations of nature, which yield the amount of wool they now get.

We desire to call the attention of our wool-growers to the propriety of keeping a distinct flock for producing long, fine wool, for worsted and mousseline de laines. Several millions of dollars have already been invested in erecting buildings and machinery for the manufacture of these fabrics in Massachusetts.

Mr. Samuel Lawrence of Lowell, a gentleman of great experience in the manufacture of woollen goods, thinks the Cotswold sheep one of the best varieties to keep for growing long wool. They clip from seven to nine pounds a head, when well kept. Mr. Erastus Corning, of Alabama, has a flock of one hundred and thirty ewes, which will shear seven and a half pounds each. These were selected with great care a few years since in England, by an experienced flockmaster, Mr. Sotham, who in company with Mr. Corning, imported them with a fine herd of Hereford cattle. A writer in a late number of the Boston Cultivator commends in high terms for the production of long, fine wool, a cross of the Leicester ewe with the fine Merino buck. A few millions of sheep, growing wool well adapted to the manufacture of mousseline de laines, would doubtless pay a better profit than those yielding either felting wool or coarse blanket wool.

To get these, we must improve our native sheep by judicious crossing, and by altering their keep. We must wisely adapt our means to the end we have in view—understanding aright the cause and effect from the first preparation of the soil to the packing of the staple in the sack for the market.

From the N. Y. Observer.

FRUIT TREES.

Age of Apple Trees—do Natural Trees outlive the Grafted?

"Apple trees live to a great age. There is a tree on Peak's Island, in Portland harbor, that has been known to bear fruit every season for more than a hundred years."

The above paragraph was in your summary of last week; and as I observe you have a small agricultural department in your paper, I take the liberty of submitting a few remarks suggested by the above extract.

The fact stated is unquestionable. I can well remember, when it was a common thing to see apple trees not only of vast age, but of immense stature. When I was a child, I can distinctly recollect the remains of an orchard, on my father's farm, the principal part of which the British had cut down, for fuel. Eight or ten trees only remained, a venerable cluster in one corner of the field. Almost every tree was not far from being two feet in diameter, and in form more like the lofty and wide-spread oak, than our present apple trees. Some of them were from forty to fifty feet high, and of proportional breadth. I can well recollect, aso, the gradual decay of these early tenants of the virgin soil, and the remarkable tenacity with which they clung to life. As one large limb after another decayed and fell, new and vigorous young shoots would spring forth and grow with astonishing rapidity. I recollect one tree in particular, whose limbs all decayed and fell off, one after another, till nothing but a hollow trunk, reduced to a perfect shell, about *eight* feet high, remained. And yet this apparently lifeless cylinder sent forth strong shoots near its top, which grew and bore fruit for many years. And it is now but a few years since the last remains of this ancient orchard were eradicated from the soil.

What rendred the longevity of these venerable trees the more striking was, that on this same farm was another orchard of *ten acres*, that had been set out with great care, only a few years before the revolutionary war, and was then too small to tempt the depredations of the enemy, and these trees long ago put on the appearance of premature old age; and now scarcely a solitary tree remains to remind one that the ground was once an orchard. In fact, it is many years since it lost that name. This orchard, I may add, had been grafted with great care, with a choice variety of fruit, and when I first knew it, was flourishing and productive.

I have stated these facts with some particularity, for the sake of suggesting some inquiries, as the following:

Is it common, now-a-days, to meet with very large and aged apple trees, except where they were set out on the virgin soil of the country? And if not, as I suspect will be found to be the fact, to what cause is the decay of our later planted orchards to be ascribed? We know, by sad experience, that many other kinds of trees, which once grew, in all these regions, almost spontaneously, and bore fruit abundantly, as the peach and plum, for instance, now require to be cultivated with the greatest care, and even then are exceedingly shortened. Many a time, when I was a boy, have I, after eating a fine peach, said to my companions, I will now plant this stone, and, if my life is spared, in three years, I will eat of its fruit; and as often have I realized the fulfilment of the prediction. In those days our hedges were loaded with peaches, which from their mere abundance, the very hogs disdained to eat, except to crack the stone and eat the pit! This fact I have witnessed with my own eyes. Why, then, has it become so difficult to raise peaches? Is it to be imputed to any change in the climate? or to the exhaustion of some particular property of the soil? And does not the same cause operate on our apple orchards?

But there is another inquiry which I wish to submit. Are not all these large and aged apple trees the production of *the natural fruit?* Can any man point me to an apple tree one hundred or seventy-five years of age, that was grafted, as our present method is, on the stock, or that was grafted in any way? Every man knows that a grafted tree is merely a continuation of the old one; and, therefore, though its existence be prolonged by insertion into a new stock, it will, notwithstanding, in a few years, put on all the appearances of premature old age; and the sooner, as the process of grafting has been the more frequently performed with the same variety.

We have become so fond of grafting and budding, that most men disdain a natural tree, however vigorous, except for a stock to be tortured and murdered; or, if success attends the transformation, to be consigned to an early death. But is this extreme wise? Where did our delicious, grafted fruit come from at first? And although the seed will not always produce the same variety, yet some of it will, or others still more excellent.

I will venture then, to suggest, in conclusion, that if we would cultivate more natural trees, of all kinds of fruit, and letting them stand till, "by their fruits ye can know them," and then preserve the good and destroy the bad, we shall not only obtain new and improved varieties, but greatly prolong the life of our trees. On the present procedure, one thing is certain as the course of nature—our finest fruits must soon fail. Of this we have striking evidence in the general failure of the Newton Pippin, which was once as universally fair as oranges, and of a large size, but now often small and knotty. Other examples might be given: but I must stop—my sheet is full. A LONG ISLAND FARMER.

GAPES IN CHICKENS.

MESSRS. EDITORS:—From all I have seen and heard on the subject of what is called the gapes in chickens, it is a disase which is not generally understood. I shall therefore give you my opinion on its nature and cure. This spring, having my chickens attacked as usual with the gapes, I dissected one that died and found its *Bronchus or wind-pipe*, (not the throat,) filled with small red worms from half to three-quarters of an inch long. This satisfied me that any particular course of feeding or medicine would not reach the disease. I therefore took a quill from a hen's wing, stripped off the feathers within an inch and a half of the end, trimmed it off with a scissors to about half an inch wide, pointing it at the lower end. I then tied the ends of the wings to the legs of the chicken affected, to prevent its struggling; placed its legs between my knees, held its tongue between the thumb and fore finger of the left hand, and with the right, inserted the trimmed feather in the windpipe (the opening of which lies at the root of the tongue,) when the chicken opened it to breathe, pushed it down gently as far as it would go (which is where the windpipe branches off to the lobes of the lungs, below which I

never detected the insect,) and twisted it round as I pulled it out, which would generally bring up or loosen all the worms, so that the chicken would cough them out, if not, I would repeat the operation till all were ejected, amounting generally to a dozen; then release the chicken, and in the course of ten minutes it would eat heartily, although previous to the operation it was unable to swallow, and its crop would be empty unless filled with some indigestible food. In this manner I lost but two out of forty chickens operated on; one by its coughing up a bunch of the worms which stuck in the orifice of the windpipe and strangled it—the other apparently recovered, but died several days after in the morning; in the afternoon upon examining its windpipe, I found a female worm in it differing from the others by branching off at the tail in a number of roots or branches between each of which were tubes filled with hundreds of eggs like the spawn of a fish; and although the chicken died in the morning, the worm was perfectly alive in the afternoon, and continued so for half an hour in warm water. While I was examining it in a concave glass under a microscope, it ejected one of its eggs, in the centre of which was an insect in embryo.

From this fact, I have come to the conclusion that when the female worm breeds in the chicken and kills it, these hundreds of eggs hatch out in its putrid body in some very minute worm which probably after remaining in that state during the winter, changes in the spring to a fly which deposits its eggs on the nostril of the chicken from whence they are inhaled and hatched out in the windpipe and become the worms I have described.

There is one fact connected with this disease—that it is only old hen-roosts that are subject to it; and I am of opinion that where it prevails, if the chicken houses and coops were kept clean and frequently whitewashed with thin whitewash, with plenty of salt or brine mixed with it, and those chickens that take the disease, operated on and cured, or if they should die, have them burned up or so destroyed that the eggs of the worms would not hatch out, that the disease would be eradicated.

I am also satisfied that the chicken has not the disease when first hatched; several broods that I carried and kept at a distance from the chicken-house where the disease prevailed, were entirely exempt. And chickens hatched from my eggs where they had never been troubled with this disease, were perfectly free from it; and a neighbor of mine who built in the woods half a mile from any dwelling, and has raised fowls for six or seven years past, and has frequently set my eggs, has never had gapes among his chickens.

With my first broods of chickens, there was not one escaped the gapes. But all that have been hatched since I had the chicken-house and coops well whitewashed inside and out, with thin whitewash, with plenty of brine in it, and kept clean, have been exempt from the disease, with occasionally an exception of one or two chickens out of a brood.

In operating on the chickens, although one person can effect, it is much easier done to have one to hold the tongue of the chicken while the other passes the feather down its windpipe, and by having a small piece of muslin between the fingers, it will prevent the tongue from slipping, which it is apt to do upon repeating the operation.

Yours, &c. C. F. MORTON.

N. Y., Aug., 1844.

PLOUGHING ORCHARDS.

If well done, and the trees not run over nor lacerated, is found to be a difficult work. To make it easy, get a short one-horse whipple-tree about fifteen inches long, and attach one of the horses by long traces to the plough; fasten the other horse before it, and let them go *tandem*.—A careful boy or man rides the forward horse, and another holds the plough. After the intermediate space between the rows has been ploughed in the usual manner by horses abreast, as near to the trees as convenience and care will admit, finish the rest with the tandem team, rigged as just stated. The long traces will allow the plough to run as near the trees as is needed, and the short whipple-tree can scarcely be made to touch a tree. Well tested by experience. J. J. T.

WHEAT.

We select the following paragraph, says the Southern Planter, from a long and interesting report upon the wheat crop, as particularly worthy of attention:

"A new variety of wheat, which has been very highly recommended, is the improved flint. Some of this has been obtained from the proprietor, General Harmon of Wheatland, New York, and distributed to the members of the national legislature and various distinguished agriculturists, by which means it will undoubtedly be tried very extensively hereafter throughout the whole country. Gen. Harmon's account of it is as follows: "The improved flint wheat has been improved from the old flint, by selecting the purest samples, and sowing them on sandy and gravelly limestone land, so that the berry is now larger and whiter, and the bran or hull very thin; the heads are longer; and the straw too is stiffer, and not as subject to lodge as formerly. This is the most valuable variety grown in this section of country. It bears a good yield, producing a beautiful berry, weighing 64 lbs. to the bushel, and producing more superfine flour to the bushel than any other variety I am acquainted with. It is not affected by the Hessian fly as much as many other varieties. The same gentleman has paid very considerable attention to the culture of different varieties, and makes a remark which deserves consideration. 'The greatest objection to new varieties from warmer latitudes, is, that they are not hung to stand our winter. I have sown the white May Virginia for five years; the first two years I was pleased with it; since then, it has been failing; it has not withstood the winters well, and the heads are growing shorter, and the berry more red.' He also thus speaks of his mode of culture: 'Thirty years ago we were in the habit of ploughing in the most of our wheat on smooth land; we used the common two-horse plough: but we became satisfied that some of the seed was covered too deep; the plough was given up, and the harrow has been used since. A few years since, I built me a three-cornered harrow, and, instead of teeth, I put in the common cultivator teeth, which I have used on my summer fallows, and for covering my wheat; the last time in going over it, I go north and south. This leaves the land a little ridgy and protected from the cold northwest winds, which are severe here in the month of March after the snow is off; when the roller is used after the harrow, it has been more killed out; and when the soil is made very fine, it is more liable to be winter killed. The common horse ploughs bury the seed too deep; the lately constructed quadruple plough answers very well.'"

Proper depth of Seed.—"As the result of some experiments respecting grain of different kinds—wheat, rye, barley and oats—in Germany, it is said that 'from two-thirds to three-fourths of the grain plants had their root stalk only one inch under ground, and exactly these produced the most stalks; one-fourth of them had their roots only 1½ inch deep, and had only half as many stalks as the first; at 2 inches deep, there were only 4 in 100; and 2½ inches deep only 9 in 1,000; but only one of them produced stalks, while in the first rye and wheat showed only 23-5 to 4 1-5 stalks. Winter wheat at 1 inch gave 765 root-stalks out of 1,000 as remaining in the earth, of which 34-7 produced stalks; at 1 to 1½ inch, of 1,000, gave 215 root-stalks, of which 2⅛ produced stalks; at 2 inches, only 17 root-stalks of 1,000, of which only 1 produced stalks. From this, it is clear that shallow sowing, if the seed is only so far covered as to sprout, and the germ is protected from immediate contact with the air, is preferable to laying the seed deep, because it springs up quicker, and acquires a stronger growth, and has hardier plants.' 'The climate and period of sowing, as well as the weather, will of course be considered in determining the depth. The warmer, dryer, and especially the more windy the climate, the deeper (other things being equal) the seed must be laid. Wet and cold weather requires a shallow sowing; a dry and hot season a deeper burying of the seed.' 'A *shallow* sowing is one which covers up the seed only half an inch thick; a *moderately deep* sowing, 1½ inch thick; and if from 1½ inch to 3 inches in depth, it is called *deep sowing*. The choice of seed is very important; and the remark may be repeated here, made in the last report, that the grain which is most suitable for nutritious bread, on account of containing the largest portion of gluten, is not the best for the seed. The neglect to observe this may have sometimes contributed to influence the crop. It is also well ascertained that grain threshed by the threshing machine yields seed far less suitable, on account of its being broken, than that threshed by the hand-flail. The amount thus obtained too from the sheaf is supposed to be one third less."

Rust.—"The question as to the best methods of preventing the diseases and attacks to which the wheat crop is exposed, is one of deep interest to the agricultural community; and some suggestions on this subject may not be inappropriately subjoined to the account of this crop.—The time when the field is struck with rust, seems to be just at the time of ripening. A remarkable fact on this subject is stated in a report to the New Jersey Agricultural Society.—An extraordinary field of wheat, supposed to be out of danger, on a hot day became drenched by a sudden shower, which came on between one and three o'clock, P. M. All was still; and on the passing away of the shower, the sun came out intensely hot. The owner went into his field to examine his wheat, which he found much pressed down by the shower: he immediately perceived a continued ticking, or snapping noise, in every direction. The straw was fine and bright; but, on examining it, he found it bursting in short slits one-quarter of an inch long, and the sap exuding from it. A day or two after, the whole field was darkened with rust, and the wheat nearly ruined. Another instance of the same kind is also related. The conclusion stated is, that the loss of the sap, running out and becoming dried on the straw, occasioned the rust.

"Mildew and rust are said to be more common now than before the Hessian fly made its appearance. Previous to that time the wheat was sown the last of August and the first of September, tillered largely, obtained great strength of roots, and was but little injured by winter frosts; the effect of which was to produce strong bright straw, with but few leaves; the consequence of which is but little mildew and rust.

"To avoid the fly, manuring high at seed time and sowing late was resorted to. This was attended by mildew and rust. Being sown late the plants had no time to tiller, or multiply and strengthen their roots and stalks; of course, the winter weakened and thinned the plants, which made the wheat still later in the season; and, when highly manured, the straw was full of leaves, very succulent, usually mildewed, and almost rusted. 'The means of prevention are—first, a good, dry, loamy soil, well prepared by cultivation, and not too recently manured, that by cultivation there may be a good assimilation of manure to the soil; the more complete the better. Cover the seed about two inches deep, either with drill or plough, that it may have good hold of the soil, and not be thrown out by winter frosts.' It is also said the French chemists, having witnessed the blighting of human food, have suggested the use of charcoal, to absorb the excess of the ammoniacal and other salts, which, taken with the plant in excess, during the warm showers, when the berry is

growing, cause the stalk to burst open, its juices to exude, and the seed to shrink. The result is stated to have been satisfactory. The mode of using the charcoal, as suggested, is by strewing it, well crushed, and as soon as possible, over the land; and that it be well moistened with soft water, by means of a watering-cart. Ashes have likewise been recommended by Liebig and others. Some suppose they, or some alkali, are necessary to dissolve the silicious substances, to furnish strength to the stalk. Liebig supposes it to furnish a silicate of potash—an ingredient in the growth of wheat. Some soils, peculiarly free from rust, it is said, are supplied with unusual quantities of potash. It has also been recommended, as a means of secur ng a good crop, notwithstanding rust, when the plants appear thin on the ground, in the spring, to sow spring wheat among the fall wheat. This plan has been resorted to with good success in Canada.

"Bone manure is likewise mentioned as very useful for grain, as bone is said to contain many valuable principles, such as fat, gelatine, carbonate and phosphate of lime. A striking experiment in confirmation of this is mentioned. The distinguished Berzelius, in 1817, is said to have analyzed a soil which had yielded crops of grain, from time immemorial, without manure. It was found to contain small fragments of bone; and after it had been boiled a long time in water, afforded a solution which yielded a precipitate to the infusion of galls. From this result, he conjectured that the ground had been a field of battle."

Smut.—From amongst several expedients to prevent the wheat from *smutting*, we copy the following which we know to be efficacious:

"The wheat, after being thoroughly washed, to be soaked ten or twelve hours in salt water, as strong as it can be made. It is further said that no injury will result if it lies in the brine for several days, provided it be in a cool place. After thus soaking it, let it be limed. Another person recommends that the seeds, when placed in the brine, be stirred up thoroughly, so that the light seeds may rise to the surface, and be skimmed off; afterwards, that the brine be drained into a tub, and the seed thinly spread on the floor, and sifted with quicklime, at the rate of one gallon to a bushel, and, after carefully stirring the lime through the seed a few times, and then sown. The seed which underwent the perfect cleaning gave a return of pure wheat; and that which was sown in its natural state was infected with smut, and had a mixture also of chess. In a Northumberland report on agriculture, it is stated that Mr. Culley, who grew annually from 400 to 600 acres of wheat, had but one instance of smut in forty years, and this was when the wheat was not steeped. Another experiment was tried on seed, in which were a few balls of smut—one-third being steeped in chamber lye, and limed; one-third steeped in the same, and not limed; and the remainder without steeping or liming; and the result was, that the seed pickled and limed, and that pickled and not limed, were free from smut, but the other had smutty ears in abundance. Another experiment was tried, by taking a peck of very smutty wheat, of which one-half was sown in its natural state, the other half washed as clean as possible, in three waters, soaked two hours in brine strong enough to bear an egg, and dashed with lime: the result was, two-thirds of the unwashed was smutty, but of the pickled and limed seed there was a full crop, without a single ear of smut. A similar experiment, somewhat varied, is the following: Of four sacks of smutty wheat, one sack was soaked in strong brine only; one prepared with lime only; one was soaked in strong brine, and then lay in lime all night; and the fourth was sown without anything: the result was, where brine only was used, now and then there was a smutty ear, but not many; where lime only was used, there was about the same quantity of smut; where lime and brine were used, not a single smutty ear could be found; and where nothing was used, it was a mass of smut. In another experiment, however, mentioned in the Southern Planter, wheat salted at the rate of a quart of salt to a bushel succeeded effectually in preventing smut."

FALL GRAFTING.

Capt. Josiah Lovett, who is distinguished for his success in raising superior vegetables and fruits, has given in the Magazine of Horticulture, his mode of fall grafting, by which he is enabled to get fine fruit from the scions the next season.

"Your remarks in the November number of the Magazine, for 1843, page 423, respecting my mode of procuring the specimens of fruit presented on several occasions at the Horticultural Society's rooms, last autumn, is partly incorrect; they were not procured by budding, but by grafting. I have practised budding with fruit buds for some eight years past, and occasionally succeeded in getting good fruit from them. It is now three years since I have begun grafting with fruit wood in autumn, (and I never heard of any person attempting it previous to that time) thus far I have been eminently successful with the pear and apple, (occasionally with the plum;) the grafts thus set have been more certain to mature their fruit, than the trees from which the grafts were cut; this can only be accounted for by supposing the sap to flow slower in the graft in the spring, in consequence of there not having been a perfect union with the stock in autumn; and the grafts, not blooming or setting their fruit quite as early in the tree from which they were cut, escape the injurious effects of our late spring frosts and cold north-east storms, to which, in our climate, we are so subject.

I select a healthy shoot for a scion, with fruit buds on it, I have them set a foot long with one or two side shoots. Immediately remove the leaves, and cut on one side in a sloping direction, to a point, the cut from one to two inches long: then with a sharp knife I begin at the point and cut just within the bark, up about half an inch above the commencement of the incision on the opposite side; then select a thrifty upright shoot, on a healthy tree, cutting well back, making a short stump; cut this stump in the same manner as the scion, reversed; and carefully but firmly bush one with the other; secure with bass or Russia matting, and cover with clay; or I prefer to mix equal parts of beeswax and Burgundy pitch; a less quantity of rosin will answer in the room of pitch; soften to a proper consistency with hogs' lard, and melt together, and spread on cotton shirting; and then cut in strips of one half to three quarters of an inch wide, and after uniting graft and stock, bind with this the cotton side next to the bark. The composition ought not to come in contact with the bark, as the bandage should be left on through the winter. If the grafts are carried any distance before uniting to the stock, it will be very important that the leaves be cut off under the tree, and the ends, as soon as possible, dipped in wax or something adhesive.

Very respectfully, your obedient serv't,
JOSIAH LOVETT.

Beverly, March 5, 1844.

N. B.—The mode of grafting above described is very similar to what is called whip-grafting by some, though I take much less wood with the bark than I have seen gentlemen do who graft by that mode.

From the Connecticut Courant.

PRODUCTIVE FARMS.

To a person not familiarly acquainted with the history and statistics of English husbandry, the extreme productiveness of the farms of that country, will appear incredible. Nearly nine-tenths of the cultivated lands in Great Britain and Ireland, are rented to tenants, who pay, usually, from four to five pounds sterling per acre annual rent. Where is the farmer in this country, who could live under such a burden? Here a farm comprising a hundred acres is often rented for one hundred dollars, and even at this rate the tenant has a hard task. The cultivation, even where there are a large number of acres in grass, will little more than pay the rent and taxes; but in England the result is widely different. The tenant who there pays £5 per acre annual rent, and finds all appliances, obtains not only a comfortable living, but in many cases wealth, from the prosecution of a business which here, with like burdens, would doom him to want and misery.

In 1811, Irwin estimated the produce of one English farm of eight hundred and ninety acres, at £8,578, or $38,000! The quantity of manure applied was 13,746 one-horse cartloads in one year, and 10,250 the next! Now admitting the rent of this farm to be $12 per acre, and the cost of manure and its application $12 more; and if to this sum we add, for interest, or expenses, taxes, and the various contingent expenses of cultivating, &c. $12 more, we shall find, upon striking the balance, that there will remain a profit of $10 the acre, amounting in the gross aggregate to the sum of $10,000 clear gain to the tenant in a single year!

In the vicinity of London, a hay farm, comprising one hundred and sixty acres was rented. The rental in this instance was $12 per acre, amounting in the whole to $1,920 per year. A very heavy expenditure was required for manure—probably as much as many a New England farmer would have been willing to give for the land, and yet the tenant succeeded, and has since become wealthy, and with no other income than the produce of his farm.

In Ireland, a poor man hired an acre of land, erected his cottage, purchased manure and farming tools, and the first season cleared all expenses and had a balance of £8 left. And yet that Irish peasant, in addition to the expenses and outlays above enumerated, had a church tax to pay, and to be at the expense of purchasing his own seed, and maintaining a family of four besides himself and wife. The frugality of the Irish peasantry is proverbial. But there was something more than mere frugality at the bottom of this man's success. There was *thorough cultivation*—a thing which in New England may be said to be wholly unknown. This is the mystery, and the only one. That Irish peasant, with like expenses, would have starved here on forty acres with our cultivation.

THE PEACH.

With the fertile soil of our country, we have but little difficulty in growing peach trees until they are three or four years old, when they are attacked by the worm in the root, or a disease called the yellow, and frequently by both. In either case the tree dies in two or three years.

The following remedies have been found perfectly successful in preventing the worm in the root. When a tree is first set out in the orchard, apply three quarts of fresh or unleached wood ashes, and add ashes every spring. Another method is to pour chamber-lye around the roots of the trees several times during the spring and summer.

The method pursued by Mr. Pell, of Pelham, Ulster county, New York, is to put one-half peck of fine charcoal to the roots of each tree when first set out in the orchard, and adding a quantity each spring.—*B. G. Boswell, Philadelphia.*

USE OF GRAPES.

Dr. Underhill strongly advises the culture of grapes, both on account of the profit to be derived from the sale of them, and from their value as food to sick and convalescent persons. At a late meeting of the New York Farmer's Club, Dr. Underhill made some highly valuable observations on this subject. After fifteen years' trial with various kinds of grapes, he prefers some of our natives, and recommends the Catawba and Isabella. He has three acres of the former, and seventeen of the latter. He says our people eat too much animal food, which renders their blood too thick, and causes diseases of the heart, liver and lungs. He thinks it would be infinitely better to substitute grapes and other fruit, with a little pure wine, for a portion of animal food.

From the Camden Journal.

THE DUTY OF OVERSEERS.

Mr. Editor:—I wish to give you my views on what I think the true spirit that should prompt all Overseers to their duty, and how they may best improve.

When an Overseer takes charge of a plantation, it is his duty to find, as soon as possible, the true situation of every thing on it, then to have a conversation with his employer relative to all matters which may be connected with his interest; and in this he should be particular to find out the views, feelings and wishes of the employer fully. The overseer should take charge of all, and take the same interest in every thing committed to his care as though it was his own, and more so— for if it was his own, he would not feel such a degree of responsibility resting on him, as that of another man who had employed and put so much dependence in him. This is the first step to improvement—for unless the overseer is actuated by these feelings, he will not improve, but must remain stationary. Next commences a wholesome and well regulated system among the negroes—and in this, the overseer will find use for all the wisdom, patience and perseverance mortal man can possess, for extremes either way, will prove injurious to all concerned—the overseer's feelings should be calm, collected and firm, with a desire not to inflict punishment, but from a sense of duty, he should act the gentleman amongst the negroes and to his employer, and expect to be treated in like manner from them all, for without this, all his efforts will not elevate him, nor can he command that respect which should be paid any gentleman, no matter what his occupation may be—and now, if the overseer desires to become *number one*, he has no time to loose—he should enter head, heart and hands into his various duties—he should read every thing that would improve him in agriculture, and combine theory with practice—it will greatly improve him—he should experiment on the various products of the soil every year, and the more he learns the more he will see the necessity for improvement. Nothing should pass without his notice and attention—he is not to look to this or that particular part of his duty—but all, and every thing under his care, should have his individual attention. The sick should be attended to faithfully, and in the discharge of that duty, he may improve by learning something of the art of medicine, and be able to treat all common diseases, which all overseers should do. It was once thought the cotton bag overseer was the man that might be called number one, but that time has passed by, and now the planters are anxious to get overseers who will attend to every little matter, and save expenses, and if the overseers wish to be number one, they must go with the times—they should make every effort in their power to make all the supplies for man and beast, on the plantation, and by proper attention to the raising of stock, the improvement of the soil, and to the making of every thing at home that can be made, they will soon find things so improved, that there will be an increase of not only that part of the crop that makes man and beast happy, but will greatly increase the cotton crop also. This I know from experience. Make the effort, my friends and brother overseers, and you will find what I have said to be true. Let us not be self-conceited when Providence smiles on our labors, and we are blessed with a few good crops, to think we know enough, and then become careless. No, there is no time to lose, if we intend to make ourselves good planters. In all we do, we should act from principle, and if the employer be a thousand miles from us, we should still be the same. And as changes often take place with overseers, one goes to another place, and one takes his place, and so on, that is the time if possible to be more particular than at any other time. They *should remember that golden rule, "do unto others as you would be done by."* How often I have heard employers complain of their overseers not taking any interest in any thing on the plantation, as soon as they found that they were going to leave, and I have often heard the overseers make the same complaints in taking charge of a plantation—finding every thing in such a bad condition, that it took them months to get things straight? An overseer that acts in this way, never will be number one—but they should feel it to be their duty to leave every thing as they would wish to find it. As soon as an overseer finds he is going to leave, he should have every thing in good order, and make a faithful return of all to his employer.

In conclusion, let me call on my brother overseers to unite with me in greater efforts for improvement; we have been long enough in the dark; it is our duty and privilege to come to the light and make ourselves not only good planters, but useful members of society, and a blessing to the country, and to leave means to our posterity, by which they may be able to fill more elevated stations than we are at present called to fill.

An Overseer.

From the Maine Farmer.

GREAT WASTE OF MANURE.

Not upon our land, for although injudicious application may be considered a species of waste, yet there is not so much to be complained of in regard to the application as the *non*-application of manures. The waste is in not saving, in not accumulating every thing of the kind which will fertilize the soil from which we take our crops. We know from our own personal experience and observing others, that twice as much—nay, three times as much manure may be saved—we will say saved—not manufactured, but saved, as there now is. How many sink spouts are there in the country, that are almost hourly pouring out their contents, to be floated away, *no where in particular*, and "to waste their fragrance on the desert air?" How many stables are there in the country, where there is not even the shadow of a fixture to save the urine and liquid particles of manure which are continually made there? Nearly all the barns are without sheds for manure. All that the cattle make during the housing time is thrown out of the windows, where it is exposed to the weather. The arrangement seems to be the very best in the world to dissipate the valuable parts and leave the poorest. It is, first a layer of manure—then a layer of snow—then manure—then a heavy rain—then a strong wind and sunshine—then manure, and so on. In the spring we shovel in what there is left us, and which is of such strong and stubborn material that the combined attacks of snows and rains, and freezing and thawing, and sunshine and winds, could not overcome, and this we apply to nourish our crops, and to supply the delicate and fine vessels of the rootlets with nourishment. Isn't this admirable? A little care and attention, and a small amount of labor, would enable the farmer to preserve and apply his manure in a much more judicious and saving manner. We do not hesitate to say, that we have found by experience, that when stable manure is housed until it is applied to the earth, it is one-third better—more efficacious, because more full of the necessary materials for feeding vegetation. Liquid manures are seldom, if ever, used among us. In Flanders it is a very common thing for a farmer to pay ten dollars (forty shillings of their money) for the urine from a single cow during the year. And what is the result of such a saving? Why this: More human beings are comfortably supported on a square mile than in any other country on the globe, unless it may be China, where equal attention is paid to these savings. There are various modes adopted for saving these things. One is to have cisterns into which it may run. The cheapest mode is to have some kind of compost which will absorb it. We find in the last New England Farmer a communication from Dr. Jackson, giving a very cheap but excellent mode of concentrating and preserving these fluids. His plan is the following: "Take twenty measures of dry peat and one of ground gypsum, and mix them together. Place barrels half full of this mixture in places where urine may be collected, and it will be found that the salts and ammonia of many barrels of urine will be consolidated in this mixture without giving the slightest odor, or being in any way offensive, for the salts are taken up, and the carbonate of ammonia, formed by decomposing urea, is immediately absorbed.

"This method of getting rid of a nuisance and of consolidating a valuable liquid manure, full of the most useful salts, ought to receive attention. A mixture of peat or swamp muck and gypsum (plaster of Paris) will also serve to absorb all the disagreeable gases of vaults, which will be converted into fertilizing compounds with the sulphuric acid of the gypsum and the organic vegetable acids of the peat."

Here, then, is a very simple but at the same time very efficient mode of securing the valuable ingredients of the sink and other disagreeable but *necessary* places about our premises; one which every farmer can adopt. A small pit, made with a covering to keep out sun and rains, filled with the above materials, would be a little mine of wealth to every farmer, and we may say a mine of health too, for it would swallow up all the pestiferous and noxious gases which must invariably arise from the decomposition of such offal.

SALTPETRE ON SEEDS AND PLASTER ON FLOWERS.

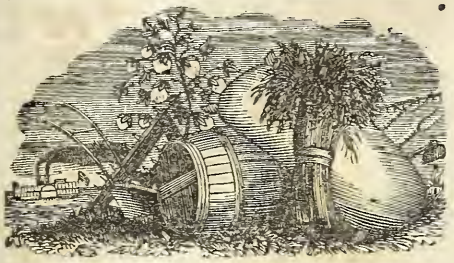
Hart Mussy, Esq., of this village, tooka small portion of the corn with which he planted a field, and soaked it in a solution of salts of nitre, commonly called saltpetre, and planted five rows with the seed thus prepared. Now for the result: The five rows planted with corn prepared with saltpetre, yielded more than twenty-five rows planted without any preparation. The five rows were untouched by the worms, while the remainder of the field suffered severely by their depredations. We should judge that not one grain saturated with saltpetre was touched, while almost every hill in the adjoining row suffered severely. No one who will examine the field can doubt the efficacy of the preparation. He will be astonished at the striking difference between the five rows and the remainder of the field.

Mr. M. also stated the result of another experiment. He has a fine, thrifty, healthy apple tree, about twenty-five or thirty years old; but it has never, in any one year, produced over about two bushels of apples. While in blossom last spring, he ascended the tree and sprinkled plaster freely on the blossoms, and the result is that it will this year yield twenty bushels of apples.—*Concordia Intelligencer.*

For three years we have published from time to time experiments and statements showing the value of the saltpetre soak for corn and other seeds, and yet probably not one-tenth of our readers use this or any other soak. For several years we have soaked all our corn with the most gratifying results. None of it has ever been touched by the grub, against which we, therefore, regard the saltpetre as a perfect protection, and it grows with a rapidity that shames the sluggishness of grass and weeds. We planted some corn this year, on the 6th of May, soaked as usual, and in just twenty-eight days it stood twenty-two inches high—ground rich but not manured this year. A pound of saltpetre in enough water to cover a bushel of corn is about the proportion.—*Louisville Journal.*

COWS.

Cows should have warm water for a few days after calving, otherwise they are very liable to colds, inflammation of the udder, &c. It is a good method as practised by many, to prepare the first drink by putting a shovelful of hot coals into a pailful of cold water, and after a few minutes take off the swimming coals, and then give the water to the cow, which must have become sufficiently warmed, and it will have acquired an alkaline quality which is considered beneficial.—*Boston Cultivator.*



WEDNESDAY, OCTOBER 16, 1844.

PLANTER'S CLUB OF HANCOCK.

☞The annual fair of the Planter's Club of Hancock, will take place at Sparta on Friday and Saturday, the first and second days of November. An address will be delivered before the club on Saturday by a member.

The friends of Agriculture, and the public are respectfully invited to attend.

TUTTLE H. AUDAS, Secretary.

Sparta, Oct. 10, 1844.

☞Editors friendly to the cause will please copy.

PROFITS OF RAISING FRUIT.

The product of one large peach orchard in the little state of Delaware was sold last year to a company in New York city for fifty thousand dollars, and it is said the company realized sixteen thousand dollars profit by the operation.—From the same orchard, fruit has been sold to the amount of one hundred thousand dollars.

ANALYSIS OF BLUE MARL.

EUFAULA, Ala., 25th Sept., 1844.

MR. EDITOR:—I wrote you from Elberton, Ga., on my way home from the West, giving my plan of preparing Cotton for market. I now forward you for publication, the analysis of the blue marl of this region, as prepared by the kindness of the Rev. Doct. Means, of Oxford, Ga.

—

Col. McDonald—

DEAR SIR:—I have made an analysis of the fine specimen of blue Marl which you were pleased to send me, and am entirely satisfied that it must contribute largely to the fertility of ordinary soil.

The productiveness of lands, you are well aware, depends upon a suitable proportion of the *earths* which compose them, and the comparative value of different marls must depend upon the constituent character of the soil for which they are designed, and the description of crop intended to be grown. Compact limestone, by an increase of aluminous earth, passes gradually into marl; and while in some instances the *calcarious* matter predominates, in others the *argillaceous* is most abundant. If, therefore, a natural soil be loose and porous, with a good proportion of sand, the *argillaceous* marl will give it adhesiveness and tenacity, and make it retentive of moisture; if on the contrary the soil is close and tenacious, the *calcarious* marl is preferable. The clay (silex and alumina) which constitutes in different marls from 10 to 95 per cent. of the mass, is best suited to tenacious soils when the *silicious* element predominates. Marls which furnish 25 per cent. of the carbonate of lime may be regarded as very rich. Indeed many locations (some within the limits of our own State, Georgia) do not give more than from 5 to 7 per cent. In the examination of your specimen, a quantitive analysis was not prosecuted, farther than to ascertain precisely the proportion of the carbonate of lime in the mass, which it was hoped would be sufficient for all practical purposes. I found it to contain of that salt 13.72 per cent, i e. every 100 grains of the marl furnished 13 72-100 grains of the carbonate. I found it also to contain *mica*, *silex*, *alumina*, and *iron*, the latter ingredient in considerable quantity; and, as I believe, in the form of the *sulphate* of the *peroxide*, constitutes an admirable substitute for sulphate of lime (plaster of paris) in soils which are designed for culinary vegetables, and especially what are called cruciferous plants, as the white and black mustard: also, turnips, cabbage, celery, red clover, &c., all of which contain sulphur as an element and ingredient, and require a soil supplied with sulphates, which by decomposition, the sulphate may be separated and assimilated to the purpose of vegetable life. *Nightsoil*, and especially human *urine*, which has undergone putrefaction, used in connection with sulphate of iron (green vitriol) furnishes, by a change of base, the sulphate of ammonia —an admirable salt to promote vigorous growth in the class of vegetables above named.

The silicious and aluminous portions of your marl are, I think, in fine proportion to meet the general distribution of the *earths* in most natural soils in your region of country. On the whole, your Alabama marl seems to resemble the Burlington county marl, New Jersey, and especially in containing shells and *iron:* the latter being by no means a common ingredient of marl; and I trust, if found in sufficient quantities, will brighten the auspices of an enlightened and patient industry—redeem hundreds of exhausted, unproductive acres, and clothe them afresh with annual luxuriance of a healthful and vigorous vegetation.

With sincere regard, yours, &c.,

Oxford, June 29, 1844. A. MEANS.

For the Southern Cultivator.

FORM OF A LEVEL.

MR. EDITOR:—There is diversity of opinion in regard both to the form and span of a Level that best adapts it to agricultural purposes. Some say 10 feet span, others 15, or more. I propose to make a few observations on this subject, to my brethren of the plow, and with as much brevity as possible, knowing that details on such a subject are apt to be uninteresting. I prefer the span of about a rod, for reasons presently to be assigned. The dimensions and the mode of constructing the one which I have used *personally* for many years in preparing for horizontal plowing, and which I have found very convenient, are as follows: legs 11 feet long, ¾ or ⅞ of an inch thick, 3½ inches wide, in the middle, tapered down at each end to 1¼ inch; cross them at 2½ feet from one end, and separate the other ends to 16½ feet; fit them together by means of a half mortise or *joggle*, and secure with screws; fit in and secure in like manner, a cross piece; from the large part of one leg to the large part of the other, it should be 2 or 2½ inches wide, and as thick as the legs; one other cross piece, about the size of the last, fitted and secured like it, near the top of the legs (above the cross) completes the instrument. Now for its advantages. 1st. More can be accomplished by it than by a narrow one in a given time.—2nd. It is lighter in proportion to its span than any I have seen, and may be made still lighter than directed, if strength be left in the middle of the legs, where the lower cross-bar is attached, and where all the strain falls in using it.—3rd. The ends of the legs (the feet we will call them) rest so obliquely on the ground as not to sink much, even in ground recently plowed.—4th. The point where the plumbline is attached,—in the middle of the upper cross-bar—is remote from the lower cross-bar, where the indications of the plumb are seen, thereby securing greater accuracy.—5th. It is more *conveniently* portable; the cross of the legs may be put on the shoulder of even a man of low stature, and the instrument carried to, or from, or about the field, without any exertion of the arms or hands. Of course it is carried in the hand like all others, when in *actual use.*

A simple and sufficiently accurate mode of ascertaining the perpendicular of the level, is as follows: put the feet as near on a level by the eye as possible, and mark where the plumbline strikes the lower cross-bar, then reverse the feet, putting each one where the other stood before, and mark again where the line strikes; the centre between these two marks, is the correct perpendicular. Now to prepare for laying off drain ditches, move one foot of the level until the plumbline settles to the centre mark, then raise one foot two inches by putting a block under it, and mark where the line strikes or settles to, and put figure 2 over it on the cross-bar, then raise the same foot one inch more or 3 inches altogether, mark where the line strikes and put 3 over it; then raise, mark and place the figures for the other foot in the same manner. The instrument is now prepared for *leveling*, ascending or descending at the rate of 2 and 3 inches to the rod.

Chopping with a hoe to indicate to the plowman the course that the level has gone, is, in my opinion, a very poor, though common expedient. I prefer the following mode: split out a sufficient number of little sticks, 12 or 15 inches long, about as large as the little finger, and sharpen them at one end, one of which is to be stuck at the foremost foot of the level, at each successive stride, bringing the hind foot to the stick from which the fore one was last taken. The grounds of my preference are,—1st. *Expedition*, instead of the delay necessary to make several chops with a hoe; at a word, the stick is stuck down and the level is again in motion. —2d. *Accuracy.* The point is precisely shown, where the fore-foot was taken from, and where the hind one must be placed.—3d. *Economy.* A little boy, incapable of handling a hoe for any length of time, can carry and use a sufficient number of sticks; moreover, the plowman who succeeds, can see the course of the row and follow it, without the necessity of an extra hand to lead his horse; and further, the zigzags in the row, occasioned by furrows and ridges, and oth-

er slight inequalities in the general surface, may be corrected without any detriment, but with actual advantage to the work, by the plowman leaving such sticks as stand out of the general course, on the right or left, as circumstances require.

COLONUS.

Covington, Sept. 28, 1844.

For the Southern Cultivator.

MR. EDITOR:—Amid the political excitement of the day, it is pleasant to see the progress and success of enterprises intended to promote, and which will promote, the prosperity of the South. The story of Swift about the blade of grass is more truthful than old. To the South, it is equally as important to save as to grow this additional blade of grass—and he may be regarded as a benefactor who shall practically teach the one or the other. Lest, however, I should incur the imputation of Southern infirmity—of great talk and little work—I shall at once give you the result of my examination of a mill, recently put in operation by A. N. Verdery, Esq. This mill grinds the ear of corn as it is taken from the stalk; that is to say, grinds shuck, cob, and grain at the same time..

The shuck, after being passed through the mill, presents less in substance than might be supposed, unless, indeed, a large portion has been converted into meal. That which is distinguished in the mass is soft and elastic, and is in small shreds.

The cob is not distinguished from the finest particles of the grain.

The grain is chopped into hominy, such as is usually adapted to table-use; but of course intermixed with a large quantity of meal.

The experiment was made with the whole ear of corn, stripped of the shuck, and the mill ground in less than two minutes a bushel of hominy, in which, as before stated, the cob was a distinguishable component.

No experiment as to time was made with the ear with the shuck on, owing to the want of skill in giving the mill its proper *feed*.

This enterprise is not claimed as original, though the proprietor has never seen a similar mill in operation. Those who have tried the experiment on a smaller scale declare that seven bushels of corn ground up with the cob is equal to twelve bushels according to the usual mode in which it is given to stock. If there be superadded the benefit of the shuck, it would be but reasonable to suppose that the saving to the planter will be one half. Again, experience, limited as it is on this subject, proves that stock, especially old horses and mules, are more uniformly kept in a thrifty condition, when fed in this way, and are certainly less liable to disease. The cost of mills will vary from $50 to $300.

From the Maine Cultivator.

MANURE COMPOST.

Manure is virtually the farmer's capital, the bank, if we may be indulged in the expression, upon which he can alone draw for those important and essential accommodations, without which his industry and economy in other matters will be of little or no avail. There is not a farmer almost anywhere whose resources in this particular are not amply abundant, and whose farm might not, in a short time, be brought to almost any degree of productiveness the owner could reasonably desire. Nature has provided, by a wise economy, that nothing which has once been inspirited with the energizing, identifying principles of life, shall be worthless in the great work of perpetuating and nourishing its kind. But it is not simply to the animal and vegetable kingdoms, that the farmer is to look for the means of enriching his soil. The various mineral substances embedded in, and constituting, to a certain extent, the surface of the soil upon which we tread, are endued with certain distinctive and emendatory properties which render them efficient assistants in the labor of improving and enriching our fields.—Even the hard and compact substance of flint is capable of yielding, upon decomposition, a principle essential to the growth and nutriment of plants; while the various mineral substances of our common fields and gardens, are capable, when commingled in proper relative actions, either of weight or measure, of evolving principles not only highly beneficial to the health of plants, but indispensably necessary to their successful development and growth. In the formation of compost manure, one thing, however, is indispensable, and this is, that we attend strictly to the nature and constitutional character of the soil to which it is to be applied. If it be of a clayey or argillaceous texture, the basis of the compost intended for its amelioration, should consist principally of sand. But if, on the contrary, it be of a sandy or silicious character, the compost should be mostly of clay. Soils that are naturally *humid*, should have such alterants applied, and in such quantities, as will bring them to a proper consistency; while those that are arid and liable to injury from a too rapid descent or evaporation of water, must be modified by the application of such remedial agents, as will tend to confer unctuosity, and prevent the possibility of injury from such a cause.

The most tenacious clays, and the most barren sands, may, by the application of such materials as tend to modify their obvious defects, be made wonderfully productive.

SAVE YOUR OWN CLOVER SEEDS.

Bear in mind that the second growth of clover, the rowen, contains five times the seed that you would find in the first cut. You can now gather the heads with cranberry rakes; or you can mow the clover and thresh it as you would thresh grain. You may raise better seed in your own fields than you will be likely to purchase at stores. You can have the large northern clover for mowing, if you choose; but you cannot always purchase the seed in the spring. The straw will be worth something—though not *quite* so much as if to cut when in blossom, notwithstanding what fancy writers may say.

You may obtain very pure herds grass seed when you sow on the green sward furrow in August. You can sow herds grass alone, and though weeds may come up with your grass, the winter will kill them, and you will have nothing for your sickle or your cradle but pure herds grass. When you raise seed for your own use you need not care if red top is mixed with your main crop. Your herds grass may be worth as much as coarse meadow hay, after you have threshed off the seed.—*Mass. Plough.*

A Recipe to Cure Diarrhœa.—Have a little bag made out of new linen, strongly sewed, of about four inches long and one inch and a half in diameter; stamp it full of wheat flour, as full as you can get it; tie the bag when filled, and boil it for an hour in clean water; then take it out and let it get cold; rip open the bag and take off the outer crust, which the water occasioned, take of the chalky part a tea spoonful in tea (it matters not what kind of tea) every hour. As soon as the patient feels revived, let him slack and take half a tea spoonful every two hours, and so on, diminishing the dose and time as the patient feels relieved, so as not to create costiveness. When I used this medicine, I took it without tea, but it is hard to swallow, keeping a little piece in my pocket which I used occasionally. The cure will be effected in about six hours. This innocent medicine has been sufficiently tried, and effected cures when all other remedies proved of no avail. As this medicine can be had without money or price, the writer of this assures the public of its entire efficiency, and wishes that every family may be in possession of this valuable recipe.—*Virginia Valley Farmer.*

MR. AND MRS. CHAPMAN'S
BOARDING AND DAY SCHOOL.
No. 228 BROAD ST., AUGUSTA.

☞ THIS Institution has been under the direction of its present principals for six years, and the success which has attended it has enabled them greatly to increase the facilities it affords for the education of young ladies. Provision is made for thorough instruction in all the departments of female education, from the elementary English studies to the higher branches of literature and science. The next term will commence Tuesday, October 1st. Pupils can enter at any time during the term, and will be charged for the time they are members of the school.

Tuition $8, $12 and $15 per quarter, according to the age and standing of the scholar. Music and French at the usual rates. Board $15 per month.

REFERENCES.—Rev. C. S. Dodd, Rev. W. T. Brantley, Rev. G F. Pierce, Dr. W. H. Turpin, Mr. J. M. Adams, Mr. D. Hand, Augusta; Gov. Crawford, Milledgeville; Dr. E. E. Jones, Madison; Col. Wm. Jones, Warren; Dr. F. George, Jasper; Mr. W. B. Munro, Columbus.

ECONOMY.

STANFORDVILLE, GA., October 22, 1844.

Mr. Editor:—I propose in this communication, to give to the readers of the Southern Cultivator, a few thoughts connected with facts touching the subject of economy. The low price of cotton for several years has brought about a perceptible change, at least with a great many. There is more dependence now than formerly on our spinning wheels and looms for the clothing of our families. There are several of my acquaintances who do not buy any part of their negro clothing; and the good ladies of our country have applied their willing hands and hearts to prove to the world that they can manufacture clothing for their husbands and sons, that will make them appear as respectable as if they were clothed with goods that had passed through a custom house. Should not these efforts of the ladies stimulate the men to look well to their ways and means, and give their wives all the encouragement that the nature of the case requires; provide for them all the necessary conveniences, such as good cards, wheels, looms, warping bars, and spool frames, and not suffer their wives, as some men do, to be put to the necessity of going to a neighbor's to warp a piece of cloth. Perhaps the wife, in the course of a year, may lose a week in those kind of errands, while, if the husband was of the right kind of grit, he would make a pair of warping bars in one day, which, with care, would last to the third generation. There has a favorable change taken place with some men in this section in their manner of doing business, viz: they pay the cash for all their dealings as they take place. This is good economy, as goods for the cash can be had for at least from 8 to 12½ per cent. lower than they can be obtained on a credit; and when the cash system is carried out, how easy it is to settle up the year's business at Christmas, which is looked on as the time for settlements amongst planters. Not that I advocate the cash system any farther than is practicable: there are many men who are not prepared to stand up to it, therefore it is economy for them to have the good resulting from credit so far as it may be to their advantage. At the same time, no man should buy an article merely because he is getting a long credit on it, as pay-day will surely come and will not tarry, no not even for a rainy day. But after a man has contracted a debt he should use all the means within his power to be punctual in payment. If he is not ready when his debts become due, he should by no means be seen to slip around to avoid meeting his creditor, but should come up with a suitable deportment and frankly acknowledge his inability to discharge his obligations, and make the best arrangements he can with his creditor. This is good economy, as it gives some confidence and saves unpleasant feelings to both parties.

It is bad economy for a planter to undertake to make a crop with a worn-out set of tools, as the work is harder in every particular, nor will it be near as well done, neither will there be as much performed as could have been with good sharp tools. A good hoe-hand can do enough more work with a good hoe in one week and with more ease, than he could with an old, dull hoe, to pay for the good hoe; two good axe-hands can, with first rate axes, do more cutting in any given time than three can do with indifferent ones. Any man that has worked on a plantation, I expect, has done enough to have found that there was a great difference between a poor tool and a good one. A planter need not expect to have good plowing done with shackling plows and plow-hoes, and without good plowing it is idle to expect a good crop.

I am of opinion, Mr. Editor, that it would be good economy with us planters to increase the number of our sheep and reduce the number of our cows, as I know from experience that one cow, well kept, will yield more milk and butter than two or three without any extra attention. For any planter who has a plenty of land to afford sheep a good range, I consider them the most profitable stock he can have, taking into consideration the small amount it requires to keep them. Sheep, with a full supply of pasturage, with frequent changes from one place to another, or from one pasture to another, require but very little feeding through the winter. The best feed we have for sheep in this part of the country is cotton seed and good green fodder, and by giving them sufficient old fields to range on, this might be almost or entirely dispensed with. It will not do to keep sheep in small enclosures long at a time, let their feed be what it may. It is bad economy to feed sheep on sheaf oats. I have said to keep them up or in a small field, and feed them on oats, they would be soon fed to death; and I was not far from the truth, for I never have known sheep to do well when fed on oats long at a time, but altogether to the contrary. I have never found but that sheep do as well here as they do in Virginia, and as regards the ewes having lambs, they do much better, for it is not uncommon for lambs there to be frozen to death immediately after being dropped, which I have never known to be the case here. If we would keep the briers and burs out of the way of our sheep they would yield us as good a coat of wool as sheep do in the northern states, and so far as I have been able to judge, the quality is as good, after taking into consideration the difference in the breed, as we have none of the best blood amongst our sheep, that I know of.

I am, Mr. Editor, yours respectfully,

JOHN FARRAR.

P. S.—Your correspondent, Mr. Haygood, made some very justifiable remarks respecting seeds and seeds-men, in the Cultivator of the 23d instant. I think I can put Mr. Haygood in a way to keep in a stock of good seeds on a more economical plan, than to depend on seeds-men for them, viz: after once getting the kind of seed that suits him, to save his own seed from them. I have not bought any seed since I have come to the state, and perhaps have as good cabbages, beets, &c. as those who buy their seed every year. My plan for saving seed is to take as many of the best cabbages as I want for seed just before hard frost sets in, cut the root and part of the stalk off, and dig a trench deep enough to bury the heads, leaving the tops a little out of the ground, and lay some corn-stalks or boards over them in cold weather—in the spring they will take root and run to seed. Trim off all the weakly sprouts; save the best only for seed—should they get lousy, smoke them with tobacco or sulphur. By pursuing this plan, I have kept a stock of good and pure seed. Beets, turnips, &c. may remain in the ground where they grew till the last of January, or later, if cold weather—then take up as many of them as are wanting for seed, trim off all the small roots and set them out to bear seed. If the weather is dry when this is done, they must be watered. As they run to seed, trim off all but the best branches, the remainder will produce good seed without deteriorating. J. F.

OVERSEERS.

MR. EDITOR:—I read, with pleasure, in the last number of the Cultivator, an article on the "Duty of Overseers," written by "An Overseer." If all our overseers would read, adopt, and act up to the principles laid down in that article, the happiness, as well as the profits, of the planters would be greatly enhanced, and the agricultural profession, in every way, vastly benefitted; for a great deal depends on overseers. I have had many in my employment. I have taken uncommon pains in the selection of them. Have always secured men of the highest reputation, and never parted with but one before his year was out. Yet I can say that I have not had a single one, nor have I ever known a single one, who comes near up to the

full performance of his "*duties*," as laid down by the writer of that article. My experience is, that the first object of an overseer, when he comes on a plantation, is to convince the owner that he is a very big man, who knows all about planting and managing negroes, and has been accustomed and is entitled to have his own way: and that the owner, on the contrary, as he wears broadcloth, reads books, and perhaps dabbles in politics, must necessarily be entirely ignorant of planting and of his own interest, and would do well to let him alone while he manages his affairs and makes a fortune for him. His next object generally is to make it apparent that every thing is out of order or deficient. He soon discovers that your land is poor or worn—your mules broken down—your gears lost—your wagons, fences, buildings, all require repairing—an entirely new set of plantation tools must be provided for *his* use and on *his* plan—you are uncommonly backward in your work, and he doubts whether your corn and bacon can be made to hold out. He endeavors to impress it upon you that he sets out under the most unfavorable auspices, and if your crop is a failure, it is not his fault. On the contrary, if it succeeds, the utmost credit will be due to his skilful management. The next thing he does, is to flog every hand upon the place on the most trivial pretext, to let them know that he is master. And if you have any favorites that he can discover, he flogs them first and the severest. All this impertinence and brutality the poor planter must put up with the best way he can, for he knows that if he discharges his man for these things, he will have to discharge his successor for the same, and ultimately yield, or do without an overseer at all. He consoles himself with the idea, that as the year advances, he will draw the reins a little and have something of his own way. In this, he is often disappointed, and finally gives up in despair, or parts with his overseer after it is too late to repair the injury he has suffered. I have found, however, that with most overseers, by good treatment and forbearance—by winking at small faults—conceding every thing you can, and refusing to listen to complaints, unless very aggravated, one may get along after a fashion for the year or perhaps two. But the idea of having any of your plans exactly carried out, is almost hopeless. And whatever improvements you desire to effect, must be introduced with the most skilful diplomacy, or forced in by downright bullying. Your new plow is rejected with scorn—your imported breed of hogs is ridiculed without mercy—your crop is done for if worked in the least different from what your monitor has always found the best way. You must submit to all this with a good grace; and congratulate yourself, if you can, by any half-way compromise, get a tolerable experiment of any of your projects. And as soon as you have declined a re-engagement, you will find every thing at sixes and sevens. Plows, wagons, carts, all break down, and cannot, somehow, be repaired—fodder is plenty and covers the bottom of your stables. The corn will certainly last till Christmas, and that is all he cares for. If your meat is poor or badly cured, it is of no consequence, he will not have to eat it. The fences will do for his time: and why should he push on work and get in advance for another crop, the credit of which will enure to his successor. His intent is at an end as soon as he knows he is to leave, in every thing except to stretch the number of your cotton bags by packing light, that he may tell how many he made for you with such a start as he had.

"An Overseer" has drawn a picture of overseers as they should be. I have given you one of them as I have found them. And my experience has been among the best of the class, and not a few of them.

What is to be done? I say with "Franklin," whose articles I have seen re-published in the Cultivator, the planters must adopt new rules as to overseers. They must take their business entirely into their own hands, and require as the *cardinal qualification* of an overseer, that he shall obey their orders and carry out their plans promptly, cheerfully, accurately, to the letter and in the spirit. The interest of the overseer is temporary, limited, and often adverse to the owner, as his reputation, he thinks, depends on the amount of the crop for the given year. The intent of the owner is fixed, continued and universal. Every thing belongs to him, and he wants the use of them hereafter as well as now. He must look years ahead. He must sacrifice present gains for advantages hereafter. His plans must embrace the contingencies of a distant future, and must not be thwarted by the narrow views and contracted aims of a temporary agent. If overseers will follow the advice and exhortation of "An Overseer," it will be greatly to their advantage as well as to the advantage of the planters. But as it is not in human nature for a man to take the same interest for another, in all respects, that he will for himself, the planter will find it worth the trouble to watch over his own affairs under any circumstances. Taking overseers as we find them, he who does not, these times and with the prospects before us, should at least keep his eye upon the sheriff.

AGRICULTURAL SOCIETY IN HOUSTON CO.

July 4th, 1844.

A portion of the planters of Houston county met this day at Perry, for the purpose of forming an Agricultural Society.

On motion of Gen. B. H. Rutherford: Dr. Chas. West was called to the Chair, and Col. J. D. Havis requested to act as Secretary. It was then

Resolved, That the Chairman appoint a committee of five, to draft a suitable constitution and bye-laws for the government of the Society.

Dr. D. B. Hamilton, S. Felden, J. C. West, T. M. Furlow and Dr. A. T. Calhoun were appointed that Committee.

The meeting then adjourned to the first Tuesday in August to receive the Report of the Committee. CHARLES WEST, Ch'n.

J. D. Havis, Sec'ry.

—

August 6th, 1844.

The Meeting convened this day, according to adjournment, Maj. James M. Kelly in the Chair; J. D. Havis, Secretary.

The Chairman of the Committee appointed at the last meeting for drafting a Constitution, made the Report of said Committee, which being adopted, the Society went into the election of officers, which resulted in the choice of the following: Gen. B. H. Rutherford, President; Vice Presidents, Judge D. Gunn, James McKinney, Capt. George R. Clayton, Dr. Charles West, Dr. C. T. Woodson, Maj. A. Smith, J. C. West, Dr. Bradwell, Maj. Belvin, Rev. A. T. Holmes, Mr. Cliett, T. M. Furlow, Esq., Maj. J. M. Kelly and Jesse D. Havis; Recording Secretary, Dr. David B. Hamilton; Corresponding Secretary, Charles Rice, Esq.; Treasurer, Dr. A. Calhoun.

A subject for discussion on the first Tuesday in October (our first regular meeting) being chosen, the Society adjourned.

JAMES M. KELLY, Ch'n.

Jesse D. Havis, Sec'ry.

SELECTIONS, EXTRACTS, &c.

AN ADDRESS.

Delivered before the State Agricultural Society, at their Meeting at Greenville, on Wednesday, the 11th of September, 1844, by John Belton O'Neall, and published in conformity to their Resolution.

On looking over this audience, I am tempted to ask each and every one, what is your occupation? Nine out of ten would answer, it is that of tilling the soil. Of the remaining one-tenth, almost every one, in a greater or less degree, has something to do with it. Of South Carolina, therefore, it may be truly said, her business and life is Agriculture. Yet in no part of the world, has less been done to give her the entire benefits of that business in which she is engaged. Until very lately, she has looked on the good around her, and has been content to waste, instead of using it. The deserted and desolate fields, and the groaning forests, as they fall before the axe, tell us too truly, that we have scarcely ceased to be the pioneers of Agriculture.

Still something has been done to recall the people to their true interests. This very Society, meeting annually for the last four or five years in Columbia, and embodying a great deal of practical, as well as theoretical knowledge, has done much. So, too, the District Societies, organized throughout the State, and annually collecting the Farmers together, and inducing them to think and write about their respective systems of culture, have created an interest and rivalry in farming, which has led to great and valuable results. This very meeting, intended to call out the Farmers of the mountain District, and to give to them the benefits of the State Agricultural Society, and to receive from them, in return, that stock of information which they possess in relation to their local agriculture, speaks for us in a voice not to be misunderstood, that South Carolina is at last thoroughly aroused to her dearest interests. Can I add anything to the interest of this occasion? If I can, duty as well as inclination will prompt me to do so; but I fear that a Lawyer and a Judge, although long deeply interested in Agriculture, will not be able to set before you, the matters which should interest you, in that light which a more experienced, practical Farmer could shed. Still, as you have desired it, I will try; if I succeed, all which I wish is obtained; if I fail, the attempt has satisfied the claims which you have upon me, and may open the way to some other, better qualified, and more successful than I may be.

On an occasion like the present, as a part of the Address with which I am charged, it may be well to consider first, briefly, two of the many popular objections urged to Agricultural Societies. It is supposed by some, that theory and practice are at war with each other; in other words, book-farming is one thing, and real, practical farming is another. But there is here a great and abiding mistake, founded in, and grow-

ing up by prejudice. Agricultural writers and Societies make, sometimes, it is true, mere suggestions—they are tested—it found to be good, so far, great benefit has been conferred upon the people; if, however, they fail, little harm has been done. But in general, Agricultural Societies do not rely on speculative suggestions. Their members are Farmers, understanding perfectly their respective modes of culture; each has tried experiments, and when successful, these are communicated, and others are thus encouraged *to try*. For example, can any thing in the wheat crop, be more important than a certain means of preventing *Smut?* A brother Farmer, John S. Carwile, Esq., many years ago, communicated to me his specific, which consisted in soaking the seed wheat during the night previous to sowing, in a solution of blue stone, in the ratio of one pound of blue stone to every five bushels of wheat. After many trials, my experience enabled me to say to the Newberry Agricultural Society, that it was a perfect antidote to smut, and my report, thus made public, has been spread throughout the grain growing communities, and many a farmer has been thereby essentially benefitted. Again, in Agricultural Societies, experiments in manures, and the crops adapted to the different soils, are made by various men, and the results are, in their reports, given to the people, so that the community have the opportunity not only of profiting by one man's success, but also even by his errors. These examples of practical results will be enough to remove one class of prejudices.

It is however urged by many a Planter, whose advantages of education may not have been as great as another's, it is useless for me to become a member of an Agricultural Society; I can neither write nor speak. It is true, when the elegance of erudition is combined with the practical knowledge of the Planter, as is so beautifully illustrated, in the bright example of the untiring President of the State Agricultural Society, it adds many charms to the usefulness of such a member. But this is not expected of every one. Like the trees of the forest, one may be more towering or more fruitful, still each has its place, and is useful. Every farmer—every man who tills the soil, is an important member of an Agricultural Society. We are in Society for the express purpose of combining every thing which can be gathered together. An Agricultural stream, is like your own Saluda; it is made up of hundreds of minor streams, some greater, some less, until they dwindle down to the drippings which fall from the summit of the Table Rock. We want the experience of every one, in the culture of his crop, whatever it may be. From that which he considers important to his success, we will find something beneficial to others. Let no one suppose that he cannot tell, or commit to paper, a plain statement of whatever he considers material to his success as a Farmer. I know that every one who has the gift of speech, or who can write a letter, can do it. For he who understands a matter, can make it be understood by another. In the Society of which I am a member, (the Newberry Agricultural Society,) many of our most valuable Reports come from unpracticed writers, plain farmers, tillers of the soil, who themselves, at some periods of their lives, have been accustomed to hold the handles of the plow. But it is not alone in the Reports of the Society, that a member's usefulness is seen. Every exhibition of practical success in crops, raising stock, or adding to the health and comfort of his slaves, is of as much, and perhaps more importance than that which is written. It teaches by example. It says to each and all, if I have succeeded, you can succeed by the same means. TRY. Having disposed of these objections, I come now to set before you the claims of Agricultural Societies and Agriculture.

Meetings, such as this, with an exhibition of stock, manufactures and crops, are other results from Agricultural Societies. What effect they will have, a year or two hence will better enable you to answer than now. In general, they will excite emulation among the Farmers; every one will try to surpass his neighbor. This spirit leads to improvement upon improvement, and a whole section of country will put on a new face. Where barrenness existed, fertility will be found—where wasteful habits of farming were common, more prudence will take their place. In all our rolling country, from the mountains to the flat lands of the seaboard, what more wasteful, impoverishing style of Agriculture could be adopted, than plowing up and down the hills? Yet that has been the universal habit until of late years. The consequence is, that the State is scarred all over with gullies, and the wasted hill-sides, bald and barren, stand before us, our reproach and punishment. Cultivation in drills, and horizontal plowing, or plowing around the hills, corects this evil. Agricultural Societies are the means of communicating this information, and inciting Farmers to try it. In a hasty trip to Asheville, in June last, I was delighted to see the improvements in Agriculture, which had taken place in Buncombe, in the last four years. One farm, within four miles of Asheville, presented, what is not common in this country, a mountain knob, plowed horizontally from base to summit, and smiling in corn and grass. Such an example, on the highway, could not, I was sure, fail to create a spirit of emulation, highly favorable to Buncombe. And in this expectation, I was not deceived. Everywhere, it seemed to me, she had stripped herself to struggle for the prize—*the blessing of skilful Agriculture on the poor land of the mountains;* and in part she has already received it. Can you not, my countrymen, in like manner strive, and in like manner succeed? If you have the will to try, I know you can and will.

Associations of men for all purposes are essential. Without society man could not exist. In the very morning of creation, God declared, "it is not good that man should be alone:" he therefore provided an help-mate for him, in lovely, smiling, erring, suffering, yet faithful and angelic woman. This principle of help, thus recognized and pointed out as necessary to man in the beginning, has descended to him ever since, not only in the blissful relation of husband and wife, but also in all the other various relations of life. Separate action seldom accomplishes much. Combined action is irresistible. These remarks will be better understood by plain men, from a few practical illustrations. If one Farmer, in some retired section of country, pursues a course of husbandry which makes his place blossom like the rose, what does he accomplish? He blesses himself and family; but as to the community, I could say of him, in poetic language, "Full many a rose" blooms "to blush unseen, or waste its fragrance on the desert air." Let him, however, become a member of an Agricultural Society, and his success will be their success, his example their example, seen, known and followed by hundreds. In the performance of any work, when much is to be accomplished, numbers are sought and obtained, as the means of accomplishing it promptly and easily. If a Farmer has his logs to roll, a house to build, or his wheat to cut, his neighbors are called in to aid, and that which his own force could only have accomplished with a great expense of labor and time, is the work of a day. Just so it is with an Agricultural Society. Individual improvement has been for more than an hundred years in the field, and has accomplished but little. Associations for Agricultural improvements are, comparatively speaking, of recent origin, and yet they have crowned the land with all the honors of successful husbandry. A Society in a District gathers in the people to the work, points out that which is to be done, and all, with the desire to surpass one another, go at it, with minds and hands devoted to, and prepared for the task, and the labor of more than an hundred years of separate action is thus, by combined energy and information, accomplished in a few years.

Farmers, too, have fewer channels of information relative to their particular business than any others. Politics, Literature and Temperance, have, through papers, meetings, and other sources, continual rills, which, united together, make up the mighty streams which flow through our land, to make it everywhere glad. But until recently, Farmer's Associations and meetings were few and far between. Now and then, it is true, an Agricultural paper, periodical or address, found its way into the hands of some enterprising Farmer, who read and profitted by it. Latterly, by combining Agriculture with Temperance, in the columns of the Temperance Advocate, Agricultural information has found its way into many a house, where it otherwise would not, and has excited interest among the yeomanry of the country, which never before existed.

So, too, the District Agricultural Societies have collected the people together; have, by addresses, reports, and exhibitions of stock, interested them in the cause; have made them conscious of their power, proud of their business, and shown them, both by precept and example, how it could be made better and better, year after year.

In the pursuit of an object and end, such as ours, every thing which will excite individuals to excel, is properly resorted to. Hence premiums are offered, not so much for their value, as the evidence of success. The public rendition of these, accompanied by such an address as that which the President of this Society, usually delivers, is an honor of which the successful ought to be, and always will be proud. But its usefulness does not stop here; it arouses the spirit of emulation in others, and blesses the country with fine stock, fine crops, and beautiful farms.

The annual, or semi-annual meetings of Agricultural Societies, with their attendant exhibitions of fine Stock, good domestic manufactures, and excellent specimens of grain and cotton, are calculated to deeply interest not only us, *the members*, but also the people. Multitudes will thus be drawn together, each meeting increasing the succeeding one. The Agricultural meetings of New York fully support this assertion. That of the last Fall, which called together so much of talent, enterprise, and success from the bosom of the State, and from the extremes of the old thirteen, Massachusetts and South Carolina, with the immense crowd of citizens, men, women and children, attended by their trains of stock, and every thing else to exhibit, proclaims, in a voice to be heard throughout our broad land, that in New York the people have made Agriculture and Agricultural improvement what it ought to be, their principal object. Can it not be so *here?—Could we talk less about politics, and more about crops; have fewer stump speeches and barbecues washed down with strong drink; more agricultural addresses, meetings and barbecues washed down with cold water, think you not, my countrymen, that in a few years we should be an abundanily wiser, more prosperous and happier people than we are now?* To my mind it is clear that we should! Such Agricultural meetings as this will do much to accomplish so desirable an object. We meet, from every quarter of the State, to become acquainted with one another as Farmers, to think, to write, to talk, to hear about, and to stir one another up to improvement in Agriculture. It is, I hope, to be the parent of many other such meetings in other parts of the State, until all her people, everywhere, will devote themselves to her greatest good: For South Carolina seems to be plainly devoted, by her local position, to three great staples, rice, cotton, grain and grass. Many of these different products can be grown upon the same lands. But the swamps of the lower country are more especially suited to rice; while the region in which we now assemble, lying west of a line on the latitude of Laurens Court House, ought to be essentially a grain and grass-growing community. The intervening country, between the two designated sections of the State, is a cotton country, not usually producing more grain than

is necessary for the consumption of the inhabitants. By inattention to the plain indications of nature, how much useless labor is expended! The attempt to raise cotton, as a crop, above Laurens, is really and truly a poor compensation to the husbandman. The beautiful rolling lands and level bottoms lying within this range of country, if judiciously cultivated in grain and grass, with no more cotton than household wants may demand, would crown the labors of the year with a fully equal reward. More money would thus, fellow-citizens, annually come to your hands from the grain and stock which you would be able to grow and rear, than ever you have been able to realize from grain and cotton. And then what a change would be affected all around you. Horses, mules, cattle, sheep, and hogs, and in abundance—milk, butter, cheese, honey, and the wheat cake at every house—each family well clothed in the winter and summer from the fleece and cotton of every farm, spun and wove at home! Would you not then indeed be happy and independent? If the temporal blessings of God can ever make a people contented, yours would be that happy lot. But the advantages of such a course of farming would not stop here. The whole appearance of the landscape would undergo a magical change, hardly surpassed by the wonder-working powers of Aladdin's lamp; your old washed and sedge fields, seamed with gullies, would disappear; and your hills clothed in living green, or bending under the golden harvests, would present a scene full of interest. Instead of dilapidated buildings and fences, and perishing orchards, your buildings and fences would be substantial and your orchards flourishing. But you ask me how this would be brought about? The answer is obvious. You would have more time to devote to improvement than you now have. In a course of crops, such as I have recommended, a part of the Spring, Summer, and a small part of the Fall, would be necessary for their culture. Four, five, or possibly six months of every year would be unemployed in your crops, and would be devoted to improvement. Every man will be able to form some opinion of what he could thus accomplish. But this is not all the advantage which you might expect. Land set in grass or cultivated in grain does not require one half the labor which a grain and cotton crop demands. But the money, whence is that to come? is the question in every mind. From your surplus corn, wheat, oats, rye, barley and hay; from your pork and bacon, which you will have to spare, as the result of plenty, wherewith to raise, feed and fatten large stocks of hogs; from your cattle, horses, mules and sheep, raised and fed by your grain and grass! Let your practical Farmers, many of whom I am proud to see at this meeting, compare the results of a grain and grass growing crop, with one of grain and cotton, and the result will be 25 if not 50 per cent. in favor of the former. Will you still persist in old habits, and not at least make a trial of that, which, although perhaps new to you, yet comes thus recommended?

To bring about such results here, and to approximate as near as may be in every other part of the State, how important are Agricultural Societies! They are your lights. They point you to the good: they warn you of that which is bad: they tell you *now*, as they have often done before, that true independence is to be found in the abundance resulting from your farms. Raise, my countrymen, everywhere in South Carolina, your own hogs, sheep, cattle, horses and mules—clothe your own households by the domestic wheel and loom—manufacture your own shoes—supply your own tables with flour, potatoes, butter and cheese of your own crops, herds and dairy, and you can bid defiance to all the tariffs in the world. How much we are tributary, by our own negligence and want of thrift, to the Eastern States, has been lately pointed out most clearly by a gentleman whose zeal in the cause of his country, as well as Agriculture, has not been and will not be surpassed. From his essays you will learn with amazement the immense sums annually paid for butter, cheese brooms, shoes, potatoes and onions, all of which we could easily manufacture or produce at home. Well may we complain of our burdens under such circumstances. A part of them, we have but to will should cease, and like the Pilgrim's burden at the foot of the cross, they will roll off and sink for ever from our view.

The time is now at hand when every South Carolinian must prepare for the deadly struggle, which it is to be feared is soon to take place. The institution of slavery, whether wise or not, it is madness in us to discuss with men who "seeing will not see, and hearing will not hear!" *It is here so interwoven with every part of society, and so essential to life itself, that its destruction would be ours. Its existence and continuance depend upon our agriculture. As long as slave labor is valuable, so long will slave property be cherished. The instant it ceases to be so it will be thrown aside.* Look therefore calmly on the things around you. Your cotton is becoming annually a less valuable crop. Something in the cotton growing country must in part supply its place. May not the economy, which I have already suggested, stand us in great stead in this point of view? And will not the cultivation of provision crops, for which the rice growing country and towns of the seaboard will furnish a ready market, further eke out our wants? I have no doubt, if all South Carolina above the first falls in our great rivers, would become essentially a farming and manufacturing country, that we might, in a few years, vie with even New England To accomplish this, it is necessary that the whole resources of our State should be understood, as well as her industry properly applied. The Geological and Agricultural survey has in part, and will, I hope, fully develope them. All the region of country covered by York, Spartanburg, Union, Laurens, Greenville, Pickens, Anderson, and the upper part of Abbeville, might be essentially improved by the lime which can be obtained from the immense quarries of Limestone to be found in York, Spartanburg and Laurens. To the farmers of the beautiful section of Carolina to which allusion has been made, the lime will afford incalculable riches, when its application to soils and crops comes to be properly understood. Through the Agricultural Survey and the Agricultural Societies, this information will be obtained and disseminated. My belief is, that in the section of country to which I have alluded, the Limestone existing within it, is more than enough to restore its original fertility, and probably to increase it tenfold. To you, then, brother Farmers of the Mountain Districts of South Carolina, there seems to be no ordinary stimulant to excite your industry and direct your efforts to improvement. The earth points to her own bosom, and tells you from it to obtain that which will clothe your fields with abundance, and fill your coffers with a more certain wealth than the mines of Mexico or Peru. In the adjoining Districts, then old Pendleton, the earliest and most successful effort in Agriculture was made by the Farmers' Society. The union of such names as North, Pinckney, Huger, Calhoun, Grisham, Griffin, Maverick, Harrison, Reese, Earle, Whitner and Norton, in such a Society, could not fail to make it useful. Its existence for more than twenty years is the evidence that farmers, when once informed, and acting together, can and will persevere to the attainment of most valuable results. It is an example worthy of all praise, and ought everywhere to be imitated. Here I am glad to see the proper spirit is also at work; and your Agricultural Society, mingling to-day with the State Society, in offering Premiums, points out the beginning of what is to be a glorious day for Greenville! Glorious! because it will confer greater blessings upon her worthy population.

The people of the cotton growing Districts between Laurens Court House and Orangeburg, have not the same means of fertilizing their lands. Still, in judicious cultivation, the application of animal and vegetable manures, they can do much to restore their exhausted wastes. The analysis of cotton and the cotton plant, shows, I am told, that the food peculiar to its nutriment and growth is the *phosphate of lime*, and that this can, in a greater or less degree, be supplied on every plantation by burning the bones, which are cast away as an incumbrance, and applying small quantities of the ashes to each plant. This, beyond all question, deserves the attention of our Agricultural Societies, all of which should unite in requesting Professor Ellet to give to the public his chemical analysis of cotton and the cotton plant, and his observations upon that which is essential in the soil to its growth. Such an act on his part will add another to the many claims of usefulness which he has upon this State. If to this we shall fortunately add, through the Agricultural Survey, or the Agricultural Societies, a correct analysis of our soils, and some hints as to the kind of crops best adapted thereto, I have no doubt that we have the means within our reach of reclaiming our exhausted lands in the cotton Districts above Orangeburg. The application of the Cow Pea as a manure has been often suggested, and will, when properly applied, succeed as well with us as the clover has in more Northern and Western lands. When sown broadcast, and turned under while green, it will furnish a fine vegetable mould for the ensuing crop. On every plantation, however, a little industry will gather from the woods the alluvial deposits, the cow-pens and stables a supply of manure, which will do more to repay labor than can be found in felling the forest and preparing forest land for culture. Here the advice and encouragement of Agricultural Societies become all-important, and here their utility has been so often tested, that it can be only necessary to refer you to the Districts and sections of country where they have longest existed, for the evidence in their favor. The country from Orangeburg to the seaboard, in her inexhaustible beds of marl, has that which will make her lands more productive than they ever have been!

How much there is to encourage us, in every section of the State, is apparent from even these hasty remarks. To Yankee enterprize, could a richer field be opened? Cannot, will not South Carolinians enter upon, possess and enjoy the good which is their own, and which lies open and inviting before them? It is true, it requires labor, perseverance and intelligence; but success challenges and demands these, everywhere. The Clergyman, the Lawyer, the Physician, the Merchant and the Mechanic, must have these requisites to succeed; and still, *with us*, all of these possessions may be found as successful as in any other part of the world! Why may not the Farmer *here* succeed? He can—he may, and he will! It is only to will and determine to be laborious, industrious and persevering in agricultural improvement, and you will be successful. My fellow-citizens, *here* let us make the resolve, that *let others do as they may, we will spare no pains to improve the fair inheritance which God has given us.* It is to be observed in Agriculture, as in everything else, that success does not depend on a single effort; many an experiment must be tried, and tried again. Even success can be improved! The successful Farmer is not the growth of a day. A life of successful and active enterprise does not more than suffice to make such an one. But as in every other occupation successfully followed, every day's improvement and success furnish fresh incentives to other and greater efforts to further improve and succeed.

No higher pleasure, no more innocent and healthful pursuit can be conceived than that of the Farmer. If his own hands hold not the plow, yet in superintending, in witnessing the successful fruits of energy, industry and enterprise, in observing the continued blessing of "seed time and harvest," and the mercy of God in his rich gifts of annual abundance, he finds enough to make his heart sing with joy, and

his head bend in adoring gratitude to the King of kings.

No pursuit can claim a higher antiquity than that of the husbandman; it is hoary with the lapse of ages: it is indeed coeval with man himself. "When the morning stars sang together, and all the sons of God shouted for joy," then began the business of Agriculture.

No occupation can be more honorable. It began with Adam, the father of the human family. It was continued by Noah, the Patriarchal remnant of the antediluvian, and the beginning of the postediluvian world. It has been followed by the virtuous of all ages. It has had, and always will have, a Cincinnatus and a Washington: for in all countries, and especially in Republics, the great body of our rulers must come from amongst the Farmers. It is well that it should be so, not to the exclusion of other employments and professions; but as Agriculture is the chief pursuit, it should have its full quota of the Governors. When looked at in this point of view, how important it is that the Farmer, who may be a Legislator, a General or a Governor, should not only be virtuous, but that he should *be informed*. Such an one is only fit to rule the destinies of a free people. Each and every Farmer should seek all sources of information, through books, societies and intercourse with his fellow man: and then, whether on the farm or in public life, he can feel confident in his acts, as one who has proved "all things," and is determined to "hold fast that which is good."

From the Southern Agriculturist.

FENCES—STOCK—MANURE.

In some parts of the State, timber is becoming so scarce, that it will be a serious question, how we are to provide fences for our fields. Many kinds of live fences have been suggested and recommended. I have never seen one of any great length in any country, that would turn a vicious hog; I have my doubts whether any can be made that may *be relied on*, and I am sure that none can without vast trouble and expense, and many years of unremitted perseverance. Ditches are but little better--being equally unsafe and expensive. What is to be done then? I suggest, that instead of fencing our fields, we fence our *stock*. There are few farmers who have not a mile, many twenty miles or more of fencing to keep up, while a few hundred rails or feet of plank, will fence their stock in securely. The ready objection is, that we can not raise stock without range or pastures. Let us see. It is stated by an experienced breeder that a hog may be kept in a thriving condition on an ear of corn per day. I am sure he may be on two ears. And if they are crushed and boiled, he will fatten rapidly. Seven hundred and thirty average ears of corn will not make over six, or at most six and a half bushels of corn, which will be his yearly allowance--say ten bushels to feed him until eighteen months old. It is a good hog that will at this age, with our common treatment, weigh 150 lbs. nett. If fed in a pen, well watered and supplied with rotten wood or charcoal, which cost nothing, I will guarantee that he will weigh 200 lbs. The pork, therefore, including the cost of attention, will not be but three cents per pound. Do we raise it cheaper now, when we consider that we have to keep so many sows more, than we should on this plan, to ensure a sufficient number of pigs; that we lose so many shotes by the accidents of the range, and that we have to feed thin hogs so bountifully for a month or six weeks before killing? But there are other important considerations. We might with this system keep only the improved breeds, and by such steady feeding secure all the benefit of the improvement which is lost, when we turn them into the woods.

An accurate and very judicious farmer in Virginia, estimates that a hog well littered and properly fed, will make 250 bushels of *good manure* per annum; and hog manure is, we know, at least twice as valuable as stable manure. Now, how much corn will 250 bushels of good hog manure, put upon two or three acres, increase the corn crop? At least twenty bushels—probably much more. Here then you have a return of twenty bushels for six and a half fed, or certainly for ten fed—giving you 200 lbs. of pork, and leaving you ten bushels, to remunerate you for feeding, littering, and hauling out and spreading your manure. At this rate, I am not sure—paradoxical as it may appear—that a farmer would not make by feeding his neighbor's hog for the manure, and returning him his hog when ready for the knife. I am positively sure, that he will find it far more profitable to pen and feed his own, than to give them the best range and pastures.

And now that we *must plant corn largely*, because we *cannot plant cotton* at present prices, I hope the experiment will be generally tried. I believe that the same thing would be true as regards cattle, if the best breeds were selected, a dairy established wherever it is attempted to raise them, and their manure carefully saved. Our winters are mild; cattle standing still require less food than those ranging at will; our shocks, pea-vines, potato and pindar vines, and crab and crow-foot grasses, afford an incalculable amount of forage, which we may secure if our cotton crop is light. And our Indian corn is a treasure for feeding stock, which, in our propensity to imitate everything foreign, and to introduce grasses which our hot and dry summer will not allow to flourish, we overlook too much. It is worth all the grasses in the world. Every inch of it from root to tassel is rich in nutriment; cured and cut, its stalk is equal to sugar beet; and the cob, shock and grain, ground together and boiled, is as good as any equal amount of food known—oil-cake scarcely excepted.

If then we turn our attention to it, we shall find that we can raise stock for our own use, and also for market, *in enclosure*, as well or better than it can be done in any other country; and what a world of rail splitting it would save --of fence making, and fence mending---of corn destroyed and potatoes rooted in despite of all we can do. And how many violent and sometimes fatal quarrels among neighbors would be prevented. Perhaps the most fruitful source of bickering and open war in every neighborhood, is the lawless incursions of stock upon foreign domains. In Europe and in some parts of America, stock are mostly enclosed. On the other continent, there is rarely pretence of a fence or hedge, and in England hedges are of little real use. They would be of none against *our* swine and cattle, which are mostly of the "Liberty Boy" breed.

It may seem premature to talk of enclosing here. I do not think it is. I believe it would be profitable wherever manure is wanted; and I think few will deny that want here. I enclose for profit, though I have to keep fences against my neighbors' stock, the value of which would purchase my meat for five years to come. I invite planters to consider the matter.

HOLKHAM.

From the American Farmer.

ON MANURING IN THE HILL.

It is a deplorable fact that there are many who think they must manage their farms just as their fathers, or even, perhaps, as their grandfathers did; and who believe that to derive the greatest profit from manure, they must "dung in the hill." I propose in this brief article to show, in my feeble manner, that this is not the better way to experience the greatest pecuniary advantage, from the following considerations:

1st. It has been proved by trial that the first crop is invariably smaller where the land is manured in the hill, and if the first is poorer, I suppose there is not the least doubt that the succeeding ones will be. Two years ago last spring, we planted a small field, containing about three acres, with corn and potatoes, manuring the principal part of it by spreading on; we, however, manured about half an acre in the hill, which even had a better soil than much of the other. This was planted and hoed at the time with the other, and in the early part of the season any one would have supposed from the appearance of the potatoes, that there would have been as great a crop where manured in the hill as of those that were the other way. But this was not the case. No: in digging them the difference was very clearly perceived: I should judge that there was not more than two-thirds as great a crop on the part manured in the hill, as on the other part of the piece. Nor is this all. Last year the same field was sowed with oats, and there was as great a contrast in them as in the potatoes of the previous year. This year we have cut two crops of grass on the same piece of ground, which goes to prove none the less the truth of the above assertion. So far as my knowledge extends, I think this to be a correct criterion in all instances.

2d. Potatoes manured in the hill, are, in nine cases out of ten, eaten badly by the worms. I know the worms are a great trouble, even if the manure is spread on, but much more so where it is put in the hill.

3d. Also, where the manure is put in the hill, the potatoes grow too rank in the earlier part of the season, too much of the essential part of the manure is expended in promoting the growth of the tops.

If the manure expends the principal part of its strength in the earlier part of a season, it will not be sufficiently felt in the latter part to cause the potatoes themselves to grow to a good size: but spread on the manure, and it does not relax its agency, but continues to exert itself the whole season.

4th. Corn and potatoes, as well as everything else that is planted where the manure is spread on, will endure a drought much better than if manured the other way. Where the manure is put in the hill, the hill must of necessity be made higher than if it was spread on—and being increased every time of hoeing, it becomes of such a shape that the rain runs off as freely as from a stack of hay, irrigating the ground *between* the hills, and leaving the hills themselves almost entirely dry.

Another reason is, the seed being planted upon the manure, the roots grow too near the top of the ground, so that when there are a few days of dry weather, the ground becomes dry down to the roots, which, as a natural consequence, will greatly injure the growth of the plants. But as I am growing somewhat prolix, I will close this meagre communication by requesting those who have heretofore been accustomed to manure their land in the hill, to try the other way, and I am fully persuaded that they will be richly compensated for the experiment.

LECTOR.

From the Southern Planter.

DECAY OF PEACH TREES.

A singular fact and one worthy of being recorded, was mentioned to us a few days since by Mr. Alexander Duke, of Albemarle. He stated, that whilst on a visit to a neighbor, his attention was called to a large peach orchard, every tree in which had been totally destroyed by the ravages of the worm, with the exception of three; and these three were probably the most thrifty and flourishing peach trees he ever saw. The only cause of their superiority known to his host, was an experiment made in consequence of observing that those parts of worm-eaten timber into which nails had been driven, were generally sound. When his trees were about a year old he had selected three of them and driven a tenpenny nail through the body, as near the ground as possible; whilst the balance of the orchard had gradually failed and finally yielded entirely to the ravages of the worms, these three trees, selected at random, treated precisely in the same manner, with the exception of the nailing, had always been vigorous and healthy, furnishing him at that very period with the greatest profusion of the most luscious fruit. It is supposed that the salt of iron afforded by the nail is offensive to the worm, whilst it is harmless, or perhaps even beneficial to the tree.

From the New York Farmer and Mechanic.

THE HISTORY OF GUANO, FROM DR. GARDNER'S ESSAY.

Among the many surprising discoveries of the Spanish adventurers in America, that of islands formed of the excrement of birds was not the least. The fertilizing power of this new manure, evoking the most extraordinary growth from barren sand, in a climate unvisited by rains, was so worthy of attention, that the earlier writers are full in their accounts of the guano, and speculations on its origin. The Indians knew that it was the excrement of the flammands, cormorants, cranes, and other piscivorous birds that darken the air of their coast. They calculated the supply of manure, and fixed seasons for its removal. The birds were to them providers of food, for their sands could yield none: and hence they looked upon them with so great a reverence, that human life itself was scarcely equal to that of these birds. They called the deposit *huana*, or dung for manuring, and formed from it the verb huanuchani, to manure. But the Spaniards were not equally satisfied of its origin; they had no hesitation in referring the white, recent excrement, to birds; but the dark brown fetid *guano* seemed to be altogether another substance.

Ulloa says—when the depth is considered at which the guano is dug, it appears probable that it is an earth, although the smell might be considered against this opinton; and he is inclined to suppose that a considerable portion of earth is mixed with the birds' dung. Frezier, who examined the coast in the last century, and visited the island of Iquique, (Voy. dans la Mer Sud.) tells us that Indians and negroes are engaged in collecting guano, which is a yellow earth, believed to be the dung of birds from its smell, and the occurrence of feathers at a great depth; but he is overcome with difficulty to account for such accumulations, since, for upwards of one hundred years, there were loaded annually ten to twelve ships, and without any great diminution in its height.

It was, perhaps, this doubt as to the nature of the manure, that led the Spaniards to neglect the wholesome provision of the Incas in respect to the birds, so that now the bustle of ships and boats has driven them away. The discovery of large stores in the earth, under layers of sand, and sometimes clay, seemed to remove the necessity for new deposits; and the recent article, which, in remote times, was almost exclusively used and gathered from the several islands to the extent of 20 to 25 tons the season, is now only procured from such collections as were overlooked by them, or unnecessary to their culture, and will be soon exhausted. The accumulation of recent excrement is extremely slow. "Experience seems to prove," says Humboldt, "that one island will scarcely produce a ship load in a great number of years."

Several of the older deposits, under sand, were also worked by the Indians. The islands of Iquique, St. Lobos, Isla di Guana near Arica, are mentioned by the first writers.

We owe most of our information of the present condition and extent of these deposits to Humboldt and Mr. Winterfieldt, who resided in Peru for a number of years, and published an account in Bell's Weekly Messenger, September 11th, 1841.

Humboldt estimated the range of guano islets from 13 deg. to 21 deg. south latitude—but it certainly extends beyond these limits, for the island of Lobos is as far north as 6 deg. south latitude, and Mr. Bartlett, recently from Peru, states that they extend to the 25th degree south.

The lands about Arica and all along the the coast are extensively manured with it; hence many surmise that the guano will be rapidly exhausted, but it is probable that only a few islands are yet known, for they extend to upwards of fifteen miles from the coast. The beds of manure are usually under sand or drift, and reach various depths, from a few feet to 900 feet, according to some captains. In superficial dimensions they are equally various, from a few hundred feet to upwards of a mile and a half,

The success attendant on the importation of guano into England, gave rise to a mercantile speculation on the part of a company, who have secured from the Peruvian and Bolivian government a monopoly in the sale of the manure, for which they are said to have paid $1,000,000; moreover there is a duty of £3 the ton levied on the export.

The recent excrement is not an article of export, but that which is red or brown. It usually exhales an ammoniacal odour, which sometimes, after heavy dews, becomes intolerably offensive. It is said that at Arica the smell from the neighboring guano islands is sometimes so great as to keep off shipping—and an epidemic is even attributed to it: notwithstanding, the crews of vessels engaged in transporting it are robust and healthy.

It is well understood that the manure is found only along those portions of the coast that are continually dry, and where rain scarcely ever falls. On all coasts similarly situated, the manure will be found; but beyond, even although the birds may be as abundant, no true guano can be expected, but only the insoluble parts.

The coast of Peru is admirably situated, being the boundary of an interminable sweep of the Pacific Ocean, as a resting place for seabirds, where they may form their nests and raise their young; but under these circumstances they are intolerant of any interruption, and leave the islands as soon as an excavation is made for manure.

From the Albany Cultivator.

CHEMISTRY IN COMMON SCHOOLS.

Why not introduce the study of chemistry in all our common schools, at least the rudiments of chemistry, and especially the meaning of chemical terms? Why should not a boy, a farmer's boy, be taught the meaning of oxygen and hydrogen, as well as that of the word water? When he is now told by the papers or books he reads, that *water*, (the meaning of which term he understands very well,) is a fluid composed of certain proportions each of oxygen and hydrogen, (terms he knows nothing about,) he is at a loss. His education has left him with the idea that water is a simple element, as the ancients thought it was; and he also complains of the use of these hard words, when the fact is they are no harder than any other words to learn or to speak; but they are *new* to him, and thence he thinks them hard. All farmers should understand the rudiments of chemistry at least, and as much more as they can command; no one can be a good farmer without this knowledge, except by accident. It is in vain for writers on the subject, to try to use language that can be understood by those who have not learned the meaning of chemical terms. The word oxygen, for example, has no *common term* that would be understood more readily by such people, neither has hydrogen, nitrogen, carbon, &c. See what a list Webster makes in defining these terms. "*Oxygen*—in chemistry, oxygen or oxygen gas, is an *element* or substance so named from its property of generating acids; it is the respirable part of air, vital air, or the basis of it; it is called the acidifying principle, and the principle or support of combustion." "*Hydrogen*—in chemistry, a gas which constitutes one of the elements of water." "*Nitrogen*—the element of nitre; that which produces nitre; that element or component part of air which is called azote." "*Carbon*—pure charcoal; a simple body, black, brittle, light and inodorous." Now, what information will one who does not understand the rudiments of chemistry, derive from these definitions? None whatever. But if chemistry made a part of common education, all these terms would convey a meaning to the reader of them as readily as do those of water, atmospheric air, and charcoal. It is not supposed that the science at large could be taught in common schools; for if it could, there would be no necessity for high schools. All that is intended by these remarks, is to recommend that the meaning of all *chemical terms* should be there taught. For example, the school teacher should teach the scholars the meaning of the word water thus: *Water*, a compound fluid, the elements of which are by weight, eight parts oxygen, and one part hydrogen; by measure, one part oxygen and two parts hydrogen. Oxygen and hydrogen are gases; they are both colorless, having neither taste nor smell. Oxygen gas is heavier than atmospheric air, and it forms a portion of the air itself. It is essential to animal life and combustion. Hydrogen gas is the lightest of all gases, and hence is used in filling balloons; being about sixteen times lighter than oxygen. Now if such instruction was given in schools, there would be no complaint of the use by writers of hard names, hard words, &c.; and farmers would know just as well what was meant by the words calcareous earth, gypseous earth, &c., as they now do of the meaning of marl, plaster of Paris, &c. I can see no more reason in restricting the education of boys to the common place words of our language, in our common schools, than I do in confining them in their farming operations to the old common place routine of practice. Their education should be such as to fit them for the profession they are to follow, let that be what it may. Chemistry and botany are as essential elements of an agricultural education, as any others whatever. But how few are there amongst us who know even the meaning of the most common terms of either scie..ce? S.

LIMING LAND.

In the application of lime to land, it seems to me that one great object is generally overlooked. All the lime intended to be applied in one season is generally spread at once, thus leaving it in a kind of stratum, instead of being, as it ought to be, thoroughly mixed with the soil. Would it not be better to proceed as follows: Suppose you intend to apply sixty bushels to the acre. First spread twenty bushels carefully over the acre of ground; then turn the soil with the heaviest, or rather deepest operating plow you have. Then spread twenty bushels more in the same way, and turn that in with a medium plow passing across the previous furrow. Then spread the remaining twenty bushels and harrow that in, or turn it under with a light seed plow. This would effectually mingle the lime through the whole depth of the soil. Any one can see the reason of the thing and the advantages of it; the only object of it being the labor; but that is not more than is requisite to bring the soil into the proper condition for seeding. If wheat or any small grain be intended, then the third application can be made at the time the seed is sown. I do not much like the usual plan of applying thirty bushels one year, and three or five years thereafter thirty bushels more, and so on, unless deficiency of means prevents the whole being applied the same year. The idea generally is, that, like manure, the first application is exhausted or nearly so in three or five years, and that then another application is necessary. I do not think the lime is exhausted, but the small quantity applied having been diffused through the whole of the soil by successive plowings, the soil is not sufficiently calcareous. Now if we apply the whole quantity as suggested above, the soil to its entire depth will have become charged with it; and, if enough is applied I do not believe it will be exhausted in twenty years, if then.—*Alb. Cult.*

From the Louisville Journal.

JERUSALEM ARTICHOKES.

What we have already published in regard to these roots, ought to be sufficient to induce every farmer to give them a trial. Dr. Martin, of this state, a high authority, recommends them, after long experience, as far superior to any other root both for hogs and sheep. It is stated that they will yield on an average three times as much as the Irish potato.

Mr. D. McMillan, of Livingston county, left word at our office, says the Genesee Farmer, that he lost seventy sheep last month by turning them into wheat stubble and young clover immediately after harvest; and he wishes to know the cause of the disease.

WEDNESDAY, OCTOBER 31, 1844.

To Correspondents.—We welcome with unfeigned pleasure, the contribution of S. B. to our columns, and indulge the hope that he will find frequent occasion hereafter to enrich them with the results of his investigations in the science of Agriculture.

"A Georgia Overseer" is received, and will obtain a place in our next.

Houston County Agricultural Society.—We owe an explanation to our Houston county friends for the delay in the publication of their proceedings. The manuscript happened to get misplaced, and was consequently forgotten, until in one of our researches a few days since, it was found. In future, we trust, the same or any like mishap will not occur.

The Markets—Cotton.—Now that the business season has fairly opened, we shall resume in our next, the reports of the markets; and from time to time, we shall endeavor to present, for the consideration of our readers, some reflections in reference to the future policy to be adopted by the growers of our great staple. That something must and should be done to secure a better price for the cotton crop, is becoming more and more apparent; and that this object can only be accomplished by a diminished production, is equally apparent to the most casual observer. We grow entirely too much—the consequence of which is, that every market in the world is largely overstocked now, which must be greatly increased by the crop now coming in, which promises to be the largest ever grown in the United States. The only corrective therefore for this state of things, is a diminished production, which will enable our planters, by a just and prudent division of their labor, to cultivate other crops, while if only one half the cotton is produced, the planter will obtain for it a greater amount of money than he now obtains, with such an over-production. It is worse than folly to attempt to remedy the low prices of cotton by making more; for we now make more than the whole machinery of the world can possibly consume. Designing to recur to this subject hereafter, and to treat it more in detail, we merely throw out these hints now, for the purpose of warning our friends in advance of the suicidal policy of increasing their crops of cotton, that they may in time prepare for the necessary changes in their system of agriculture.

☞ The Danvers Eagle mentions a remarkable apple-tree, which has been in continual bloom since last spring, and has now on it apples of five different growths, and is still blossoming.

New Cabbage.—The Albany Cultivator chronicles a new variety of this plant, called the Roman cabbage, and says:—"The variety seems to possess some peculiarities. It is more solid, and heavier in proportion to its bulk, than any we have seen. It also grows very quick. The head shown us, weighed twenty pounds on the 20th of July. Its shape is oblong, and much pointed at the top. It is said to keep better than any other cabbage. The seed was brought into the country by some Germans."

☞ It is said that charcoal is a remedy for rust on the gooseberry.

☞ The rot in the potatoe, so remarkably prevalent this year at the North, is exciting considerable attention, and we see many articles in our exchanges relative to the cause—but nothing very satisfactory has yet been elicited, in our opinion. It seems most generally attributed to wet weather, at an unfavorable period in its growth. Others attribute it to *fungi*, or insects.

☞ The Agricultural Fairs, Cattle-shows, and Horticultural exhibitions, this year, are highly creditable to our more northern farmers.

☞ If you desire to be rembered and *honored* by posterity, says the Maine Cultivator, plant a few trees each year around your premises. It is the *sine qua non* of patriotism—a "good" that will survive when you are gone, and embalm your memory.

Speaking of the economising of manures Hannam says:—"Nothing must be allowed to run away in the form of a fluid, or to fly away in the disguise of a smell." These few words embody more wisdom than we often find in a lengthy essay.

In Westchester Co., N. Y., the disease in the potatoe is general. On Long Island, on heavy ground the rot is prevalent, but in light sandy soils, they have escaped. The continued wet weather is assigned as the cause by the Long Island Farmer.

Ventilation and cleanliness are very important helps to economy in the feeding of all animals. Shelter and warmth will do harm, if free and pure air is not admitted to the fattening stock. The same is true of cleanliness, so favorable to the health of all animals. The cleaner their houses and skins are kept, the more they thrive under any given form of treatment in other respects.—*Johnston.*

From the Galena Gazette.

WOOL:

The history of the growth of wool is very curious. Fifty years ago, not a pound of fine wool was raised in the United States, in Great Britain, or in any other country, except Spain. In the latter country, the flocks were owned exclusively by the Nobility, or by the Crown. In 1794, a small flock was sent to the Elector of Saxony, as a present from the King of Spain, whence the entire product of Saxony wool, now of such immense value. Before the breaking out of the last war between this country and Great Britain, Col. Humphreys succeeded in getting a few Merino sheep brought out of Spain, though their exportation was prohibited under penalty of being sent to the galleys for life.

In 1809, during the second invasion of Spain by the French, some of the valuable Crown flocks were sold to raise money. Our Consul at Lisbon, Mr. Jarvis, purchased fourteen hundred head, and sent them to this country. Previously, however, Mr. Livingston obtained a few sheep of the Spanish breed as a present, in 1792. A portion of the pure unmixed Merino blood from these flocks is to be found in Vermont at this time. Such was the origin of the immense flocks of the fine woolled sheep in the United States and Great Britain.

From the Boston Bee.

INDIVIDUAL EFFORT.

Every thing is accomplished by it—no great reform or plan for the improvement of mankind was ever originated and carried forward, save by individual effort. The masses never start up in a body and adopt this or that mode of reform, moral or political—there must be a pioneer, a leader, one to start the thing; and after him many more to put their shoulders to the work *individually*. When impressed with the truth of a thing, we should not wait for our neighbor or neghbors to think as we do, before putting our thoughts in practice—we should go right about it, do as we think is just and right, regardless of the opposition and sneers of those whose habits and prejudices run counter to it remembering that "example is better than precept," and that "actions speak louder than words."

Many people, however deeply the necessity of reform or improvement may be felt by them, have not the courage to encounter difficulties by acting up to their sense of right, especially if the sense of right be opposed to the habits and prejudices of those around them. What can I do, they say, (or think,) with so many opposed to me? But in this they make a great mistake—millions are counted by beginning with an unit, and by individual effort the most stupendous undertakings are carried forward to successful issue. In political matters, we are frequently told of how much has been accomplished by a single vote, and the fact has been over and over again proved that the most simple and apparently unimportant act of our lives has exerted the greatest influence, not only over them, but on the destinies of others. We cannot calculate the amount of good or evil that flows from the neglect or use of individual effort. Often times the neglect of doing what we know to be right, is productive of more evil than a positive wrong. We are therefore called upon to do whatsoever our reason teaches us to be right, as well as to abstain from what we know to be wrong.

Every man should feel that he is individually responsible for his acts, and that because others do what his judgment teaches him to be wrong, it is no excuse for him supinely to follow in their track. Every man should think for himself, and so thinking should *act*. In political matters, his vote should be given according to the dictates of his judgment, regardless of how others vote around him—it is his privilege, the sign of his freedom, and he knows not how much, in the aggregate, may depend upon this individual exercise of his will. In morals, in religion, it is the same. The individual is accountable, and he should never forget the responsibility that attaches to him, or fancy that the humbleness of his situation in life deprives him of the rights and privileges of manhood, or exempts him from a performance of the duties belonging thereto. In a moral or political point of view, we are all equal, and the most important results may (and more frequently do) hinge upon the actions of a poor man, as well as upon those of his richer neighbor. Let us never forfeit our independence and manhood by supineness or fawning or forget how much may be accomplished by individual effort.

USEFUL RECIPE.

I send you below, Messrs. Editors, a recipe for making a composition which will render wood entirely incombustible. It is very simply prepared, and quite easy of application, being used the same as paint with an ordinary brush. A good coat of it applied to the floor under the stoves would be an excellent precaution.

Take a quantity of water proportioned to the

surface of wood you may wish to cover, and add to it as much potash as can be dissolved therein. When the water will dissolve no more potash, stir into the solution, first a quantity of flour paste of the consistency of common painter's size; second, a sufficiency of pure clay to render it of the consistency of cream.

When the clay is well mixed, apply the preparation, as before directed, to the wood; it will secure it from the action of both fire and rain. In a most violent fire, wood thus saturated may be carbonated but will never blaze.

If desirable, a most agreeable color can be given to the preparation by adding a small quantity of red or yellow ochre.—*Buffalo Com. Advertiser.*

From the Philadelphia Saturday Courier.

PRESERVATION OF APPLES.

A gentleman from the northern part of Indiana recently communicated to us a fact in regard to the preservation of apples, which will be new to many of our readers, and valuable to all farmers. He says, that, to keep apples from Autumn to June, he places them in a shallow hole, dug as for Irish potatoes, having covered the bottom with corn-stalks or straw, and the straw with dirt to the depth of five or six inches. No shelter is placed over them. As soon as the severe weather arrives, and the ground, and perhaps the apples themselves, become thoroughly frozen, straw is again placed over the frozen heap, and the whole again covered with a coating of earth,—this time ten or twelve inches thick.

The object is to keep the first coating of earth frozen until spring, and then to cause it to thaw very slowly.

The same treatment may be given to turnips, Irish potatoes, beets, and carrots. Any of these roots may be thoroughly frozen without injury, provided they are then covered well over, and suffered to thaw by slow degrees.

Sweet potatoes are almost the only exception among roots to this rule. They are injured by a small degree of cold, and without being frozen. It is only the sudden thawing that causes the dissolution of the apple or potatoe that has been frozen. If in the frozen state, an Irish potato is put into cold water, until the frost is out, and is then cooked, it will be as good as if it had never been frozen. All these are facts, which we know from our own experience, and that of many others.

Great Yield of Pumpkins.—Chas. L. Pierce, of this town, raised the present year from a single seed, 15 pumkins weighing 384 lbs. The largest weighed 31½ lbs., and the average of the whole was 25½ lbs. each. The vine, including all the branches, measured 635 feet in length.—*Wor. Spy.*

A Hint.—Don't suffer your revolving hay-rake, and your wagon rack, and hand rakes, and whatever else you have used in the haying and harvesting just finished, to lie out in the fields exposed to the weather, but see them well housed for another season. The weather destroys more tools than hard work, with some farmers; and more valuable time is lost hunting up and repairing lost implements, than their original cost.—*Albany Cultivator.*

CUTTING TIMBER.

Mr. Buckminister,—*Sir:* One fact I wish to state with regard to the time to cut timber. I am satisfied from actual observation, that timber cut in the month of June, and perhaps July, will last twice, if not four times as long, either under or above ground, as that cut in winter, and it will not powder post.

Yours respectfully,

West Newton, July 13, 1844. John Stimson.

[There are many causes that tend to prove June a better time than winter to cut timber. The bark must be pealed immediately to let off the sap, or timber cut in June will rot as fast as any other.—*Ed. Mass. Plough.*]

MR. AND MRS. CHAPMAN'S
BOARDING AND DAY SCHOOL.
No. 228 Broad-st. Augusta.

☞ THIS Institution has been under the direction of its present principals for six years, and the success which has attended it has enabled them greatly to increase the facilities it affords for the education of young ladies. Provision is made for thorough instruction in all the departments of female education, from the elementary English studies to the higher branches of literature and science. The next term will commence Tuesday, October 1st. Pupils can enter at any time during the term, and will be charged for the time they are members of the school.

Tuition $8, $12 and $15 per quarter, according to the age and standing of the scholar. Music and French at the usual rates. Board $15 per month.

References.—Rev. C. S. Dodd, Rev. W. T. Brantley, Rev. G F. Pierce, Dr. W. H. Turpin, Mr. J. M. Adams, Mr. D. Hand, Augusta; Gov. Crawford, Milledgeville; Dr. E. E. Jones, Madison; Col. Wm. Jones, Warren; Dr. F. George, Jasper; Mr. W. B. Munro, Columbus.

BACON'S LARD LAMPS.—A new article, superior to all others for this purpose, emitting a good clear light without smell or smoke, and at an expense, counting Lard at 8 cents a pound, of about a quarter of a cent an hour.

These Lamps have been satisfactorily tested, and are recommended as "just the thing" for the use of planters, and all others who study utility, neatness and economy.

A supply of the above Lamps, with Fillers and Wicks for them. For sale by

HAVILAND, RISLEY & CO.

SOUTHERN CULTIVATOR.

VOL. II. AUGUSTA, GA., NOVEMBER 13, 1844. No. 23.

For the Southern Cultivator.

OVERSEERS.

MR. EDITOR:—There have recently appeared several articles in your paper, containing remarks, observations and strictures, with regard to the manners, the intelligence, and the capacities of Overseers, for the proper management of a Cotton plantation.

Being but an overseer myself, and having but little time and less inclination "to appear in print," though even under a "*nom de guerre*," I have waited patiently to see some reply to those communications, from a Georgia overseer.—Desparing of a proper answer, I take upon myself (by your good leave) to tell you "where the axe is wanting, at the root of the tree of evil."

All men are actuated by interested motives. Some are willing to sacrifice something towards the public weal—some, nothing at all.

Admitting the above axiom to be true in general, I shall proceed to show, that the present generation of Overseers, do as their employers do, (or rather as they *think* they do,) and therefore that it is unreasonable to expect them to turn from "the errors of their ways," until it is made their interest so to do.

But, waiving all further reasoning upon the subject, I will endeavor to come to the very gist of the subject—or the very sum and substance thereof, as we overseers say.

And first, Mr. Editor, allow me to introduce you to Col. Cottonbags—(for, sir, our farmers pride themselves upon being Captains, Colonels, Majors, and Judges, far above the honor of being the President of an agricultural society,) and an Overseer.

Overseer.—Ahem! (After the usual salutation about the Colonel's health, that of his family, &c:)—Colonel, have you engaged an overseer for next year?

Colonel.—No, sir, I believe not, (considerable pause.) I don't believe my overseer and myself can agree for next year: *he wants too much*; and times are so hard, and cotton so low, that I for *one* am determined to give no more such prices as I have been giving.

Overseer.—(Somewhat embarrassed.) What did you give him, Colonel?

Colonel.—Why $350, and found his family in sugar and coffee, and food for his horse, equal to $150. 'Tis too much, sir, too much sir, I can't stand it.

Overseer.—(Considerable pause.) How many hands do you work, Colonel?

Colonel.—Thirty odd.

Overseer.—How much in cotton?

Colonel.—About 550 acres.

Overseer.—How much in corn.

Colonel.—One hundred and fifty acres.

Overseer.—Do you raise your meat?

Colonel.—Why no, and there's the devil.—From bad management, or *something else*, I shall have my meat to buy; and what with *that*, and bagging, and rope, and negro clothes, and shoes, and other expenses, I shall hardly make more than enough to pay my overseer.

Overseer.—Have you any sheep?

Colonel.—No, sir; I was once fool enough to try *that* northern experiment, and I found to my cost 'twas a foolish one.

Overseer.—How so?

Colonel.—Why, I bought 25 head, some four or five years ago, and last year I found I had no more than I commenced with; and so I sold the things last winter, and am glad *that* trouble is off of my hands.

Overseer.—That's strange! I was at Dr. Robert Williams's yesterday, and he told me he found it very profitable raising sheep. He says, besides the mutton which his flock affords his table, the wool he sends to the factory and has manufactured into cloth for his negroes. The quantity of wool he has left after supplying his own wants, more than pays the expense of manufacturing the article.

Colonel.—Oh yes, I know the Doctor, he's one of your experimenters, full of projects and notions. But how much cotton does he make?

Overseer.—He says he tends as much to the hand as most of his neighbors; and was telling me that he raised a full supply of meat, and always had a plenty of peas and other vegetables for his negroes. He also informed me yesterday, that he was going to make a sugar-mill, and would try and make his own sugar, but at any rate a plenty of syrup this year.

Colonel.—Yes, another foolish project of the Doctor's. That, sir, has been sufficiently tried here and has proved to be a failure.

Overseer.—Have *you* ever tried it, Colonel?

Colonel.—No, but others have, and they say it takes too much time.

Overseer.—How's your pea crops, Colonel?

Colonel.—I never plant peas, sir; they kill more hogs than they raise.

Overseer.—That is strange! The Doctor told me his peas nearly fattened his hogs before he penned them, besides gathering near 150 bushels for seed, for sale, and for food for his negroes.

Colonel.—Well, I don't know how he manages. It takes all my time to gather my cotton, and I am till March at that. But, sir, the long and the short of it is, Dr. Williams is no pattern of a farmer for me. I know some things as well as he does.

Overseer.—(Smiling.) That's just what he says of you.

Colonel.—He does, hey! Well, we'll see who who *makes most clear money.*

Overseer.—(After considerable pause.) Have your negroes been healthy?

Colonel.—Quite the contrary; we lost considerable time by sickness, which caused us to "get in the grass." The negroes are so lazy, they don't half cook their victuals; and that's what makes them sick so much.

Overseer.—You don't have it cooked for them yourself, then?

Colonel.—Not I! I tried that project once, too. But they were so difficult to please, that I broke it up, and now make them cook of a night.

Overseer.—The Doctor told me he preferred cooking for his hands, for *that very reason*, for he says by cooking vegetables with their meat, it goes much farther, is more conducive to health, and a great saving in time, to say nothing of the comfort of warm food, instead of cold half cooked stuff.

Colonel.—Well, the Doctor may do as he pleases. I shan't give myself so much trouble. They may cook it or let it alone, and be —— for what I care. You appear to have taken a great notion to the Doctor. Why did you not get in with him?

Overseer.—Why, to tell you the truth, the Doctor asked me so many strange questions that I could not answer to his satisfaction, that he said he was afraid I would not suit him. I have generally been in the habit of only being asked by my employer, "how many bags we made to the hand." And as you say, all that stuff about corn, peas, potatoes, vegetables, raising hogs, sheep, goats, cattle, mode of farming, different qualities of soil, ditching, planting rice, (for he makes considerable rice, too,) and about currying horses, the time and manner, and the quantity of salt, ashes and copperas to be given to all those animals, that I confess I was non plussed.

Colonel.—(Laugh on the Colonel's side.)—Well, I'll not pester you as the Doctor did about all his notions. I know my own interest best.

As I do not desire to occupy too much space in your valuable paper, I will here close the dialogue, by adding that the overseer, having produced to the Colonel satisfactory testimonials from his late employer, that he made 8 bags to the hand, and would have made 10 had it not been for the "shedding in consequence of the drouth," engages with him for the next year—the overseer agreeing to take less wages than the Colonel had been giving. Where you find one Dr. Williams you will find twenty Col. Cottonbags; and I ask you, sir, is the picture exaggerated? If

not, is it not clear that as 20 is to 1, in the same proportion must and will be the number of overseers whose greatest boast will be (their interest guiding them) "the number of bags made to the hand."

I perceive with pleasure (though but an overseer) that the spirit of improvement in agriculture, is daily spreading in Georgia, and trust, with the aid of your valuable paper, that the day is not distant when something like the following questions will be asked an overseer, previous to employing him:

Who did you live with last year?

Does he take the Southern Cultivator?

Do *you* take that paper?

How many men worked in the field?

How many women worked in the field?

How many boys under 14 years of age?

How many women had chi'dren that year?

Did any of those children die?

Were the negroes generally healthy?

How much pork did you raise for sale, besides your own consumption?

How much corn?

How many bushels peas; do. potatoes?

How many acres of turnips?

How much small grain did you house?

How many pounds of wool?

How many beeves did you kill; and did you save all the hides?

How many acres did you cultivate to the hand?

How many acres to each horse and plow?

How many acres did you manure; and in what manner; and of what sort; stable or marl, and what quantity to the acre?

Time and manner of cultivating the various products of the farm?

Let a man be also asked *his reasons* for the success or failure of a crop.

You will confer a favor, Mr. Editor, by giving statistical information on the following heads, besides others which may suggest themselves to your mind.

What is the number of male slaves in each county of the state? Do. females?

What is the number of boys under 14 years of age, in each county of the state? Do. girls?

If possible, number of cotton plantations, with number of acres planted. Number of acres corn planted. Number acres of wheat and other small grain. Number of horses, mules, cattle, hogs, sheep and goats.

Amount of export, and the various articles. Amount of import, and the various articles.

Manufactures, founderies, &c.,—with prices annexed to exports and imports.

Number of agricultural societies in the state. Number of persons who take the Southern Cultivator.

Should this communication prove acceptable, it furnished the above statistical information—you may again hear from,

A Georgia Overseer.

Florence, Stewart Co.

Married Men.—The more married men you have, says Voltaire, the fewer crimes there will be. Examine the frightful columns of your criminal calenders—you will there find a hundred youths executed for one father of a family. Marriage renders a man more virtuous and more wise. The father of a family is not willing to blush before his children.

From the Transactions of the N. Y. State Ag. Society.

ON THE IMPROVEMENT AND PROFITABLE CULTIVATION OF CLAY LANDS.

[Remarks of John P. Beekman, President at the Columbia County Fair.]

Fellow-Citizens:—The third exhibition of the Fair of the Agricultural Society of Columbia is ended. We have now met to receive the usual address, and then to distribute the several prizes to which that exhibition has led, to those who have just won them. Here our labors, as a Society, for the year are closed; but I trust, to be individually renewed, with increased exertion, and better success for the future. Competition, such as this Society engenders, cannot but be useful to the Farmer; for here he has the evidence of the skill of his neighbors before him, and if he will not profit by the lessons these teach him, depend upon it, he is not a man for times like these.

The march of society is onward, and more has been done in the last forty years for the improvement and happiness of mankind than in many centuries before. The life of the Farmer is that of constant exertion, but when his labors are rewarded and his hopes cheered by fruitful returns, and all the comforts that necessarily follow, he will look back with pleasure on the past year that has ensured him the reward of his toil. This gratification is not lessened by a feeling of independence that springs from well-conducted efforts, nor by the estimation in which he sees himself held by an intelligent community. Under such circumstances, he proceeds with renewed energy to his work; and whether by the evening-fireside or under an August sun, he feels the same buoyancy of spirits, the same ardent desire to press forward its execution.

Seed-time and harvest, summer and winter, follow each other in quick succession, and so do the seasons of our lives: but when our summer is gone and winter is come, we will at least have the consolation to think that our lives of industry and sobriety have not shortened our days or lessened our enjoyments—and that old age will find us with no premature infirmities, with a reputation well established, and a competence to support declining years.

If the life of the farmer is a life of toil it is a life rich in the comfort it affords, and richer still in the independence which springs from it. He lives not alone for himself—he lives for the benefit of mankind. No country can prosper without him, no government exist without him; he is the lever that sets in motion all the elements that conduce to the existence, comfort and happiness of man. He has cleared your forests, made your roads, furnished the materials for building our villages and cities. He builds your school houses, erects and supports three-fourths of your temples of worship; and if education, civilization, religion, or good government is to be settled or promoted, you are sure to find in him a firm and steady friend. Generally kind and humane, the poor have in him a friend on whom they can depend; and its habits of industry, sobriety and morality, ensure stability to republican government, and furnish examples upon which the lives and habits of the rising generation are formed. The product of his industry supplies us not alone with the materials for trade; but on him, under Providence, we depend not only for existence, but for the thousand comforts that follow from labors so bountifully blest by our Maker.

To encourage this man in his great work, we have met this day; and if aught we have said, or can say, can add to his wealth, intelligence, respectability or usefulness, we have long since been repaid a thousand-fold in the benefits he has conferred upon this whole community. Last year, fellow-citizens, when I had the honor to address an audience like this, the principal subject of remark was upon the construction of the plow, and the necessity of good and careful plowing to increase our just expectations for ample returns for our labor.

The subject to which I would now call your attention is, the improvement and profitable cultivation of our clay lands.

It is not necessary, on the present occasion, that I should go into a close analysis of the different kinds of soil, but to state that the lands in this section of the State are composed principally of flint, lime and alum, or in other words, clay. The best lands for arable husbandry have a proper mixture of those three ingredients; and when they are so blended, they constitute a soil that admits of the most profitable cultivation.

In some parts of our State they are so mixed; but this is the case in a small portion of our extensive country. Here we must take things as we find them; and as in this section, for many miles up and down the Hudson river, but not more than a mile or two in width, we find a streak of clay bounded on the west principally by a streak of sand; on the east by one of flint or gravel; it becomes us to inquire whether anything can be done with this clayey portion, which is now our poorest land, to reclaim it, and make its cultivation more profitable. Chemists tell us that the most profitable lands are those which are composed of three-eighths of clay, three-eighths of pulverized limestone, and two-eighths of sand, or about this proportion; and an excellent soil for wheat is composed of three-fifths of sand, two-fifths of three earths, lime, flint and clay. I do not use chemical terms in speaking of these earths. I use only the English words, that I may be easily understood, for the object of this address is to be practically useful. I wish then, that you would bear in mind that it is the proper mixture of these ingredients, clay, sand and lime, that constitutes our most fertile soils; and it follows that, when either of these three substances is in more than due proportion to the other, or the earth is entirely composed of the one, so sterility proportionately as necessarily follows. It is not alone agricultural chemists who have made these observations, but our best farmers have long since discovered that a soil judiciously mixed, if I may use the term, is the most congenial to the easy and profitable culture of all grasses, grain and fruits.

One of the most noted chemists, Berghman, tells us, as corroborative of the preceding remarks, that these three earths enter into the composition of plants, or in other words, plants are made from them in different proportions; and he tells you how much of earth enter into the composition of wheat, oats, barley, rye, potatoes and clover.

It therefore admits not of a doubt—because the man of science and the practical farmer, unknown to each other, and by different modes of reasoning, bring the results of their respective observations to the same point.

The one tells us that these three ingredients, lime, sand and clay, constitute the best land; and the other tells us, that he finds by analysis, that these several soils enter into the composition of the plants themselves. So far, all is right. Now, what practical deductions can be drawn from the above facts? Plants, we all know, derive their nourishment from the soil they stand in, and the air by which they are surrounded. If the soil which they stand in does not admit of an easy egress of the roots of the plant through it, and likewise afford it that food most congenial to its growth, the air by which it is surrounded can do little to bring it vigorously forward.

Clay, unmixed, we know, becomes hard by heat; and it is of such quality, that the admixture of water with it makes it unpleasantly adhesive. In summer, therefore, it is apt to become dry and hard; and in spring and fall or wet weather, too tenacious of water and holds it too long for plants to thrive in. Our object is, therefore, to prevent it from baking in dry weather, and in wet to permit the moisture to pass through it, that neither excess may be injurious to the growing plant.

There is a single remedy and a simple remedy for all this; and that is, to follow up our first suggestion, confirmed by both the philosopher and farmer. Open and mix the soil, so that the roots of plants pass freely through it, and the

water likewise. How is this to be done? By drawing on what it is deficient in--lime, flint or sand. Either of these will open the soil, and answer the purpose. Manure will do the same thing, but it will not be so permanent; so will the plowing in of either green or dry crops, or chips, or stones, or leaves, or any thing that will open the earth and the progress of the roots of the plants.

A friend in an adjoining town, Claverack, tells me that these suggestions some time since occurred to him; and having the opportunities, he has adopted the practice of flooding a clay lot by a muddy stream, rendered turbid by sand in rainy weather when it is swollen; and by letting the water pass over it in this state, he has had deposited over it within a few years, hundreds of tons of sand and gravel, and it has since produced him the greatest yield of hay he has ever had.

If I understand him right, he has recovered several acres in this way, and has already been more than a hundred times compensated for the expense of the plan he has adopted. He has so managed as to dam or prevent the water from passing off at those times, until it had made its deposite: and when it had, he opened the sluices and let it pass off. The labor and the expense were trifling, but he reaps the benefit of the thought, and deserves our thanks for adopting it.

Another friend tells me, that he has drawn sand from a neighboring hillock, on a lot of clay land: and in the crops that followed, it produced as good an effect as if the land had been highly manured. The first crop upon it, after making the experiment, was a crop of grass; and he was so pleased with it, that he earnestly persuaded all he could to visit and satisfy themselves by their own personal observation. A third friend tells me, that he summer-fallowed a poor, worn-out clay lot in 1842, intending to manure it and sow it to wheat in the fall. He plowed it and drew on a sufficiency of stable manure. On another portion he drew sand and gravel, and spread it. Another portion, he left unmanured and unsanded. He sowed the whole to wheat. In the summer of 1843, the past summer, the part manured was very good, the part sanded equally good, and on the part to which neither had been applied, the wheat was miserably poor. These three experiments all tend to the same result, and to confirm the theory of the philosopher and the observation of the farmer.

The clay land in Columbia county was known by our oldest inhabitants to yield large crops of wheat immediately after clearing. Indeed, it was thought that none but clay land would produce wheat. The farmers therefore, who owned other soil, bought these clay lands solely with a view to raise wheat; and I have been repeatedly told by an old inhabitant, that farmers would purchase detached lots of clay, distant from their farms, if they had no land of this kind, for the express purpose of raising wheat. This was soon after or before the timber or growth of the forest was removed, where the ground for centuries had been annually covered with the leaves of the trees, or remains of them and the falling timber. From these deposits, there were several inches of vegetable mould created, and the sun not having had access to the ground to dry out its moisture and render it compact, it was in a fit state to yield large returns to the farmer, and it did yield them.

We have all heard of the fertility of the western part of the State, and that they raise from twenty to forty bushels of wheat to the acre. This is true: but is it generally known likewise, that a considerable portion of the land is clay upon which they raise these heavy crops. The presumption is, that they will continue to have good crops of wheat as long as this vegetable mould which the forest has been the cause of accumulating, will last, and no longer. Exhaust or remove this vegetable mould, and their clay soil will be as hard and as stiff as ours. They put on wheat after wheat—our fathers did the same—until they have exhausted the fertility, and left nothing but the residuum of the virgin clay behind; and this soil now constitutes the clay fields we see around us. We have long felt and now feel the evils of this kind of farming by our progenitors, and would be happy to apply the remedy.

The remedy in part, I have suggested in my previous remarks upon the deficiency in the soil for the speedy growth of plants; but it is not always easy or practicable to draw on lime, sand or gravel. In suggesting that remedy I will state my own experience in reclaiming clay land, and the methods I have used to effect, and leave you to judge how far it can be advantageously practised. I have owned a farm of 200 acres for say 15 years. My practise has been to stock it with a few cattle, but feed on it principally sheep—to plow only enough of it to employ two hands during the summer; not to sell any hay from the farm, but to make all the manure I could upon it. By this course of husbandry I find myself rewarded, because I have received more in immediate profits than the interest on the investment I have made would come to; and I have been enabled to manure the meadows at least three times, and several of the pasture lots. I found that I could, in most seasons, raise good crops of oats, but for the last three years I have suspended in a measure the oat crop, and gone back to wheat: and from the experience I have had, I feel the assurance that this barren exhausted clay farm, by continuing the cultivation of it on the plan I now adopt, will ultimately become, as it has already been, a source of great profit to me. It is well known that a clay soil is not congenial to the growth of corn, and that rye grown upon it does not make good flour. When it can be manured, it is better adapted to the growth of all the grasses, wheat and oats.

Knowing this, we must follow out the indication of Nature, and act accordingly. The practice I have adopted has been this: To manure an old, worn-out clay lot, summer-fallow it and plow it repeatedly; sow it early to wheat in the fall, together with grass seed. For three successive seasons, I have succeeded not only in my wheat crop, but the grass has done remarkably well the following year. Now, what prevents us from carrying out this practice? If we can reclaim a lot, can we not by perseverance reclaim a whole farm? And what, let me ask, can be more profitable husbandry than a good wheat crop followed either by hay or pasture? If then, carting on lime, sand, gravel or dung, one and all—remembering, however, that manure must be one of the ingredients to make the improvement permanent—what is to prevent the industrious and intelligent farmer from making our now worn-out clay lands our most profitable farms. Again: sow it early, sow it in August—give the plant plenty of time to cover the ground well with its foliage before winter sets in. This will afford protection to its roots, and we will not hear so many complaints about your wheat being frozen out on the clay. The leaves will protect it. I will add one word more on the subject of sowing grass seed. I sow timothy and clover—three times the quantity of the first, to one of the last.

My observation thus far has taught me that the earliest sown grass-seed does by far the best. I have sown in September, in October and November. The first did well, the second not so well, and that sown in November did very badly. I could add more on this subject, but I trust that I have said enough to be understood. The suggestion is sufficient—your own good sense will supply all that is wanting.

And now, fellow-farmers, before we separate, permit me to ask in conclusion, have you for the last year done justice to your profession, to your families and to your country?

Have you called to your aid all the agricultural reading within your reach, and taken advice from those of your neighbors who are able to give it? Are your farms generally, in a better condition than they were one year ago? Are your fields better laid out and enclosed—your waste grounds less--more of it grubbed up and improved--your ditches opened—useless stones removed, and the general surface of the ground better adapted for the raising of crops? Has your land been made richer to enable it to yield more, and have you collected a large amount of materials to increase your annual stock of manure? Are your houses more comfortable, besides of a neater appearance from the labors of the year? Have you added to the convenience and safety of your barns, to make them better adapted for the purposes for which they were built? Has your stock of cattle and horses improved, not only in number, but more in quality and appearance, and consequently in value? Have you selected, and do you raise the best kind of sheep—I mean those kinds that are most profitable to the owner? Have you the most profitable breed of hogs, and do you carry just so many through the winter as best conduce to your interest? In short, have you so farmed in all things that you have no cause of regret, because you have given to all a proper degree of attention and care?

If you have done so, you will reap the result; and I congratulate you, for you have done full justice to your profession, to your families and to your country. If Providence at the end of another year should again bring us together, from the strong confidence that I have in the intelligence and good habits of my countrymen, I feel an assurance that we shall see the good old county of Columbia marching with still more rapid strides toward all that contributes to individual happiness and National greatness.

CULTIVATION OF LUCERNE.

A "Subscriber," at Strawberry Hill, North Carolina, asks for some information on this subject.

A deep, rich, and rather light soil, is best for lucerne, and it is hardly worth while to attempt its cultivation on soils of an opposite description. The preparation of the ground consists in deep plowing, and fine pulverization. Any kind of manure suitable for clover, may be used—mixed with soil. It may be sown either broad-cast, with some kind of spring grain, or alone in drills. We prefer the latter, for the following reasons: When sown broad-cast, with or without grain, its growth is much checked, either by the grain or weeds, or by both—if a drouth occurs at the time the grain is taken off, a large portion of it dies, and what remains is so injured that the succeeding winter probably kills it. After repeated trial, we have found it very difficult to get it through the first summer and winter. Unless the weather is very favorable, so much of it dies, that it is left too thin. Having failed some half dozen times in the broad-cast mode, we tried sowing in drills with a machine, and succeeded completely. The drills were about ten inches apart, and the spaces were hoed once or twice, by which means the weeds were kept down, and the lucerne grew so rapidly that it was cut three times the first season—only about a month being required between the cuttings to produce a growth of more than a foot in height. It produced at the rate of five tons to the acre.

We should prefer sowing as early in the spring as the ground would admit of, in order that the lucern might get a start of the weeds. In the broad-cast mode, fifteen or sixteen pounds of seed is recommended—in the drill mode, eight or ten pounds, if properly sowed, will be sufficient. There is no necessity of permitting a crop to go to seed, as our correspondent suggests, as the roots are considered perennial—at any rate, they live many years. In regard to the marls mentioned, it would be better to try them, as well as lime, plaster, &c., for the effect of these cannot be positively foretold.

The seed might be had at any of the principal seed stores of our cities. Its cost is from twenty-five to thirty-seven and a half cents per pound. By the quantity it could probably be had for less.

Lucerne is greedily eaten by all kinds of stock, and it is considered highly nutritive. It may be fed green or made into hay. We know

of no plant of equal value for soiling. Its growth commences very early in the spring, and continues without interruption through the whole season. No ordinary drouth affects it in the least, after it once gets fairly rooted. The roots have been traced to the depth of more than three feet in the earth, the first season, when sown in drills. The only cultivation that it requires after the first season, is an occasional harrowing before it starts up in the spring.

From the Southern Planter.

SMALL FARMS AND THOROUGH CULTIVATION.

The anecdote of the boy carrying a stone in one end of his bag, to balance the corn in the opposite end, because his father had done so, shows in some degree the force of education and habit. This stone-carrying system is of broader application than may be at first imagined. To exemplify. A father has a field of one hundred acres of land which he cultivates because he has laborers and team to do so; perhaps fifty acres of this yield something like two bushels per acre, a little more than enough to feed the laborers and team whilst engaged in the cultivation; the son inherits it, and forsooth, because his father had done so, he continues the practice, until he finds it expedient to remove to some new country. To arrest a course like this, so destructive to lands and fortunes, I propose a few remarks. All who have noticed any thing about farming operations in Eastern Virginia, cannot fail to have observed the thirst for extensive cultivation, irrespective of the quality of land and its productiveness, and those engaged in it have found at harvest time that their crops have mostly been gathered from a few patches of land in tolerable heart, whilst the greater portion of the field required oxen in pretty good keep to collect a load of ears, more resembling awl handles than corn. In view of this fact, and in view of the immense products of the small northern farms highly improved, it is passing strange the course should be persisted in. I suggest the following one to remedy this evil: Say a man has a field of one hundred acres of land, half of which is nearly unproductive, which will require eight hands to cultivate it; let him take three of his hands from his field, and commence early in the year to haul from his woods, leaves, mould, swamp mud, walls of ditches cut through his swamp land, and any vegetable matter he may have, and apply it to the unproductive part of his field so far as it will go; and I will venture to affirm that the product of the part of the field in cultivation, will far exceed the product of the whole field in any previous year, seasons and cultivation being alike. When these sources of improvement are exhausted, let the hands above employed in improvement, remove the ground works of fences that have been standing for years, and take the soil from under them and apply it as manure, as it really is, and the product of this process will astonish any one who has not experimented in this way, and will leave your fences cleared of shrubs and briers, which yearly consume much time and labor in clearing, and so much injure fences by obstructing the wind and sun from them. This source of manure having been exhausted, if you have light or sandy land, take from your adhesive clay subsoils, clay to cover it, say about twenty-five or thirty loads to the acre, scatter the same so soon as it is deposited, so that it may have the frosts and freezes of the winter to pulverize it, and turn it under in the spring preparatory to planting corn. This will give tenacity and fertility to this kind of soil, and one experiment of the kind will embolden you to a continuance of the practice. As respects manuring, from repeated experiments, I am fully persuaded a surface application is the most beneficial on sward or fallow. I would prefer applying it on the sward in August for the ensuing year's crop of corn. When there is a great scarcity of manure, a quart of stable manure or a pint of ashes dropped on the corn hill after planting, will produce a result in the crop, that no one would anticipate who had not thus experimented, and I incline to the opinion, that it will be the most speedy way to cover over a large surface, and make a good crop at the same time. It is true that this application at first is too limited for a small grain crop, nevertheless, you have applied the quantity of manure over double or treble the surface you would have done, if it had have been applied broadcast; you will have obtained double the quantity of corn you would have made from a broadcast application of the same, and I believe you will make as much small grain from this extended surface. On the second cultivation of a corn crop, with the beds reversed, and a like application of manure, it will have diffused itself more generally over the surface than could be imagined. All I ask of the skeptical on this subject is, to make one experiment. I have frequently applied it in this way, and invariably have derived benefit from it, exceeding my expectation.

A few words in relation to the varieties of corn; in these I have experimented largely, and the result is decidedly in favor of the largest kind. Poor land will not bring large or small, and rich will produce much more of the large than the small. Of one of the small varieties I once obtained eleven ears well matured from one stalk. The appearance was very imposing, but lo! when I came to test the product of this variety with a larger one, I found one large ear to yield one-eighth of a gill more than the eleven. When the gathering of the ten additional ears, the shucking and housing, and the deficiency in yield are taken in the estimate, I think no one will hesitate in awarding a preference to the large kind. REXBURG.

From the Southern Planter.

ECONOMY OF FARM LABOR.

There is no subject of greater importance to the farmer than the judicious application of his farm labor, and there is none that receives so little of his attention. False economy often induces men to use an old worn-out tool when, for want of a good one, they lose more every hour than would pay for two. A wood-cutter with an old stumpy axe labors hard all day and is dispirited because he has nothing to show for his labor; he is scolded probably for what is entirely the fault of the tool: with a good tool he is active and cheerful, because he feels that his day's work will speak for itself. Some men use wooden pitchforks for hay; the time lost in hunting for a proper stick and in cutting it, would often secure as much hay as would pay for two steel ones; and then to see a man make five or six ineffectual efforts to stick the fork into a pile of hay, and at last take up about one-third of what he might with a good one, and having one-half of that falling back into his face, is enough to disgust any body in the world who loves to see work done as it ought to be. It is the same thing with dung forks. Give an ordinary hand a good steel fork and he will load a cart in less time than the best hand will with an inferior one—but to observe the indifference of our farmers to such things is to me, who have been used to different things, a matter of astonishment.

Raking up Hay.—As I observed in your paper once before, one man with a horse rake is as good as four and I believe six with the ordinary hand implements. Pine boards for compost should be collected whilst the ground is wet; then a portion of earth is taken up with them, which keeps them compact, and a cart carries in the bulk double the weight. The size of the manure heap depends upon the facility with which it is accumulated; what we obtain easily we use bountifully. As to the

Application of Manure.—Suppose a farmer has twenty head of cattle; he pens them in his farm-yard and hauls in trash to litter it with. In this way he may make eight hundred loads of manure, which it will take him eighty days, at ten loads a day, to haul out upon his fields. Of this probably five hundred were litter, which it has taken him fifty days to haul in. Here is one hundred and thirty days employed in hauling. Suppose, instead of this, he pens his cattle upon his ground previously broken up, on a quarter acre at a time, and hauls the five hundred loads of litter directly to these pens of plowed land, is it not evident that he gets the same amount of manure with fifty days hauling, instead of one hundred and thirty? If this process is followed, and lime added where the soil is deficient in it, the loss from evaporation and washing is less than by any other means that I know of, and certainly the saving in labor is very great.

Hours and Weather for Work.—It is bad economy to rouse your hands, as some do, by starlight, keep them at work for several hours on an empty stomach, make them guzzle down their meals, and off again to work as long as they can see, and then depend upon their feeding in the dark. Some think a little rain wont hurt, and drive on through a drizzle; the body hot from work and the skin cool from rain, induces cold, and lays the foundation oftentimes of the very worst diseases. The loss of time, and sometimes of life, from such causes, together with the doctor's bill, doubles the amount of gain that can ever accrue from such means.

The following is my plan of

Working Corn.—Lay off the corn rows deep with a two-horse plow; plant in the bottom with the usual covering; then when high enough to work, put in the cultivator so that the right hand tooth will split the edge of the furrow on each side, and the corn will be wed, and hilled a little, and the ground left light and fine, *without hoeing.* Now be not deceived here; deep *planting* is not deep *covering.* Plant deep down, but cover light, and when well rooted below, work as above directed, and your corn will bear working close to the stalk, and will, in my opinion, when the dry weather comes, bear working at least ten days longer.

I could enumerate many other points affording a fair scope for the exercise of economy in labor, but it is probable that he who will not take the hint from what has been already said, would hardly be profited by a more detailed view of the subject. I will close this communication by a single other remark upon tools in general, and one of my own in particular. It may be asked, shall we throw away our old tools and buy new ones? I answer, if your good fork is worn too short for a strong man to make a good day's work, give it to a boy, or keep it for work that may injure a new one; but never expect a full day's work from a good hand with an inferior tool.

I would mention an implement of my own invention for cutting down and picking up corn; it is the circular part of an old reap hook, with a shank bent to it, which is a little turned and driven into a short handle; with it when ground keen, a man can cut with the right hand and heap with the left as fast as one can cut and another heap in the ordinary way.

My aim in this communication is to encourage those who are without means to be their own means, and to work out their own independence by the shortest route; but do not think for a moment that your implements are complete without having some agricultural work coming constantly to you with the latest news, that you may profit by the advice and experience of others. J. H. D. LOWNES.

A NEW FASHIONED MATTRESS.—We sojourned lately at the house of a country friend, where we were treated to the most comfortable mattress it has ever been our good fortune to encounter. At first we thought it was fatigue which had converted an ordinary couch into a "thrice driven bed of down;" but we soon found that there was a most comfortable peculiarity about the bed itself, and upon inquiry we found that we had been lying upon a mattress consisting of eight or ten blankets quilted together and encased in a linen cover; this mattress rested upon an ordinary feather bed. This hybrid between a feather bed and a mattress, secures all the softness of the one and all the levelness of the other. Moreover, it is an excellent mode of disposing of the blankets during the summer.

We warrant he who tries it, never buys another hair mattress.—*Southern Planter.*

NEW AND IMPROVED COTTON GIN.—The Alabama Monitor says: We alluded a few months ago, to the fact that John H. Sherard, Esq., a wealthy and skilful planter of Sumter co., and withal a man of great mechanical ingenuity, had invented and patented a Cotton Gin, superior to any other now in use. We copy the following notice of it from the Sumter county Whig of 22d inst.:

"A few days ago we saw Mr. Sherard's new patent Cotton Gin in full operation, and we can assure those who have not seen it, that it greatly improves the quality of the cotton ginned, and is altogether a beautiful piece of machinery. It is very simple in construction and easily kept in order. The saws are nearly like those of the ordinary Gin, save a slight difference in the cutting of the teeth. The ribs are circular and revolve with the saws—behind the ribs is a cylindrical brush revolving against the saws, which takes out motes, trash and dirt; still further behind and a little below is a similar brush which takes off the cotton from the saws, and carries it over a grate, which entirely removes the remainder of the trash, dirt, &c.; Still further back is a brush with wings, which blows the cotton through a flue with a tin bottom, perforated with oblong holes similar to those of a tin lantern, through which, should there be any remaining trash or dirt, the whole will pass. This flue has one advantage over all others, it never chokes up, and consequently does not require delay of time in cleaning it.

"The whole is carried by two hands and works most admirably. A fifty saw Gin, the size of that Mr. Sherard now has in operation, will gin four bales per day. We would advise every farmer to visit Mr. Sherard and judge for himself. Mr. S. has been at great trouble and expense in perfecting his improvement, and we have no doubt his efforts will be justly appreciated by the cotton growing interest. We would remark that the improvement may be attached, at small expense, to the ordinary gin; and further, that Mr. Sherard's new gin will cost but a trifle, if any more, than those now in use."

A RECIPE FOR DR. HENKEL'S BEST PIES.

We have received from our friend, Dr. Henkell, of New Market, a recipe for making what he styles, his "best pie;" and, as our taste sometimes has an inkling that way, we have thought that it would not be uninteresting to our fair readers, who pride themselves upon serving up the dainties of the table, to give them an addition to the culinary department of household economy. As pies, however, have their genealogy as well as politicians, and are most esteemed for their particular flavor, we have thought proper, on the present occasion, to introduce a sketch of the origin of this "favorite," with the view of enlightening those who have been content to nibble a stale, flat, insipid article, because, forsooth, they did not understand the "pints," as one of our learned phrenologists would say. It seems, from the information we have gleaned on the subject, that many years ago, the good "helpmete" of our worthy friend was preparing nick-nacks for table use, and having "*run out of sorts*," as we printers sometimes do, she had barely enough of apple and whortleleberries (vulgarly termed huckleberries) left to make a pie when compounded. To throw the ingredients away would have been sheer extravagance—to mix the two together would *make a pie!* but how would it *taste* was a question to be solved. She, however, in imitation of all good house-wives, who study the interests of their family, went to work and tested the experiment by an admixture of apples and whortleberries. The pie (unlike those we printers have to digest) was found to have increased the flavor, and has since become quite a family favorite. With this brief history, and a request to the fair sex to test the experiment, we shall add the recipe: Take of finely sliced apples and whortleberries equal parts, add sugar to suit the taste, and make your pastry and bake them as other pies; and we would add by way of conclusion, that if you don't find them agreeable to the taste, just hand them over to the printer.

COLD STARCH FOR LINEN.—There is economy in stiffening the collars and wristbands of shirts with unboiled starch. Take as much of the best raw starch as will fill half a common tumbler, or a half-pint cup. Fill it nearly up with very clear cold water. Mix it well with a spoon, pressing out all the lumps, till you get it thoroughly dissolved. Next, add a tea-spoonful of salt, to prevent its sticking. Then pour it into a broad earthen pan, and add gradually a pint of clear cold water, and stir and mix it well. Do not boil it.

The shirts having been washed and dried, dip the wristbands into this starch, and then squeeze it out. Between each dipping, stir it up from the bottom with a spoon. Then sprinkle the shirts, and fold or roll them up with the collars and wristbands folded evenly, inside. They will be ready to iron in an hour.

This quantity of cold starch is sufficient for the collars and wristbands of a dozen shirts. Ladies' collars may be done also with cold starch, if the muslin is not very thin.—[*Miss Leslie.*

AGRICULTURAL PUBLICATIONS.—We must study our profession; we have many judiciously conducted periodicals, and many scientific works, and no man who has a proper pride in his profession fails to read some agricultural paper with all the zest that ever a politician devoured a partizan journal. These productions from practical farmers, amuse, interest, and instruct. They excite us to increased exertion;—inspire us with confidence in undertakings which otherwise would be abandoned upon the first failure;—give us plans, the most approved, for all our farm buildings;—make suggestions which are often of the greatest importance:—indeed, they act as "a friend in need,"—as a wise counsellor, a judicious, experienced adviser. These papers are of as much importance, and are as necessary to the planter in the successful prosecution of farming, as the political newspaper is to the statesman, or the "reports of cases" to the lawyer.—*Bowie's Address.*

CHINA WHEAT IN MARYLAND.—There has been left with us a few heads of wheat called the "Hardware Wheat," taken from the Bloomfield farm, belonging to Henry R. Smelter, Esq., near Middletown, Maryland. The history of this white wheat is thus stated: A few heads were found in a crate of China-ware, imported from the North of China, first into Canada, and then introduced into the soil of this country. It averages from one hundred and fifty to one hundred and eighty grains to the head; will yield from forty five to fifty bushels to the acre, and ripens from eight to ten days earlier than other species of wheat. The crop is now cut; it was ripe on the 24th of June, and will, it is believed, yield from forty to forty-five bushels to the acre, supposed to make from ten bushels sowing from two hundred and seventy-five to three hundred bushels.—*Frederick Herald.*

CURE OF CONSUMPTION.—A letter from Darmstadt, dated 2d September, in the *Ober Post Amts Zeitung*, describes a striking method for the cure of pectoral complaints: "The surgical operations of Dr. Van Herff at present attract great interests here. These operations have in several instances effected a decided cure in cases of tubercular pulmonary consumption—*phthisis tuberculosa.* The seat of the ulceration having been ascertained by means of the stethoscope, the matter is discharged outwardly by an incision being made in the cavity of the breast, penetrating the lungs. The cure is finally effected by medicine injected into the wound by a syringe. We have hitherto refrained from making known these operations, as we wished to await the results; but we are now enabled to affirm with confidence that in several instances the operations have obtained the most complete success, and in no case have been attended by any danger of life. We hope that Dr. Von Herff, after an extended series of experiments, will make the observations deduced from them the subject of a philosophic inquiry."—*Spectator*

THE WOOL TRADE.—According to the best calculation, says Mr. Williams, in his admirable address on the Tariff, it is supposed that there are about 34,000,000 of sheep in the United States, worth on an average about $2 a head, and yielding about 90,000,000 pounds of wool, worth at 30 cents per lb. about $27,000,000.—These sheep at three to the acre for summer and winter, would require 11,333 333 acres of land for their support, which at $12 per acre, which is considered a fair average, would be worth $136,000,000. To manufacture this clip of wool will require about 45,000 hands, who with families averaging three persons each, and amounting in all to 180,000, at a consumption of $25 per annum each, would require $4,500,000 worth of agricultural products for their support, which, at a net yield of $2,50 per acre for the market, would require 1,800,000 acres of land, worth at $12 per acre, $21,600,000. The capital invested, then, by the farmer in this business alone is about $225,000,000, and the annual value accruing to him, about 31,500,000, while the capital stock invested by the manufacturer himself in building, machinery, &c., to work up the whole annual product would not perhaps exceed $45,000,000, or about one-fifth of that of the agriculturist.—*Troy Whig.*

EAU DE COLOGNE.—The sweetest lady in the world recommended to us the following recipe for making cologne:

Mix 120 drops oil of bergamot;
120 drops oil of lavender;
140 drops oil of lemon;
60 grains of musk, and
1 pint of purest alcohol.—*Southern Planer.*

☞ The northern papers contain notices of heavy rains in all that region. Perhaps it may come our turn shortly to be thus favored.

From the American Farmer.

SUBSOIL PLOWING.

The advantages of subsoil plowing, has been very forcibly called to our mind by the subjoined article which we copy from our intelligent contemporary, the Southern Planter. It is many years since we recommended deep plowing, and it is not a little gratifying to us that we find the dread of disturbing the till pan, beginning to disappear from the minds of many, who, some few years since, would as leaf have crossed the path of a boa constrictor as break up the clay resting beneath some four inches of exhausted sand, which, from time immemorial, has answered as an apology for soil. We recollect to have called at a farm in a neighboring county, in 1839, to get our horse fed. It was in the occupancy of a tenant who had resided there for twenty years, and who, in the whole course of that time, had never penetrated the earth with the plough more than three inches. When we called, we found him engaged in *scratching* the earth with a one-horse plow, going scarcely deep enough to cover the poverty grass with which the field abounded. After saluting him, and procuring a feed for our horse, while the animal was masticating his meal, we entered into a pretty free conversation with our host, which we will here repeat, with the view of showing how absurd are the notions of men who are wedded from the prejudice of ancient prescription to old practices, and eschew all book farming as worse than nonsense.

"Why do you not plow deeper, my good sir?"

"God bless your soul, stranger, if I *was* to break up the till bottom, and turn up the red clay, I should *pizen* the ground and nothing in

the *yearth* would grow, and besides all the manure (and I've none to spare) would sink down into the ground, and my *crop* of corn wouldn't *git* no good from it; as it is, the manure I *puts* on the ground sinks into the *yearth*, and I only *gits* benefit from it for one *crop*."

"Well now, my good sir, you have given me your *theory* for shallow plowing, and, with your permission, I will give you mine in favor of *deep* plowing."

"What do you mean by theory?"

"*Theory* means the settled ideas which a man may have imbibed, as the governing principle of his action, and is to him the motive of his practice."

"I don't understand you."

"Then, sir, what I mean by theory, is this—it forms the *reason* of my doing any thing—for instance, if I were going to plant corn in this field of yours, I should manure it, because theory tells me, that the plants would require feeding to make them grow. Do you understand me now?"

"Oh yes."

"Then I'll give you my *reasons* for *deep* in preference to *shallow* plowing, and why I should mix a portion of the clay that lies beneath, with the sand above. You are fearful to break the pan, fear your manure will sink, and yet you admit that what you put on the ground, only lasts for one season, and you apprehend that, as it is, it sinks into the ground and gets below the reach of your crops. Now I think you are mistaken as to the cause of the loss of the good effects of the manure. I believe that, instead of its sinking, and thus eluding the reach of the roots of your growing plants, that it escapes from the *surface* of the earth You bury it so shallow, and expose it so immediately to the heat of the sun and atmosphere, that, upon every succeeding rain, the manure rots faster than is necessary to the sustenance of your crops—faster than the rootlets can take it up, and as the most valuable, if not, indeed, the only part of manure that is valuable, is light, and volatile—it escapes through the pores of the earth, and is wafted away by the wind, and in all probability, is carried to your neighbor's land, where if it has a suitable soil it is attracted and absorbed, to enrich his land and nurture his growing crops. I notice that your corn stalks are very small and easily broken. The reason of that is this—there is very little potash in your soil, and hence not enough to dissolve the sand, and form that flinty substance which constitutes the elastic principle that enables either grass, corn, wheat, rye, or barley to stand erect. In all virgin clays there are more or less potash, and if you turn up some of your subsoil and cross-plow it, so as to mix it with the sand, you will just supply your land with one of the very ingredients which it wants."

"Well, but the red clay will *pisen* the land, and nothing will grow on it."

"Not so. I don't wish you to turn up more than two inches at any one plowing, and whatever may be injurious to vegetation, in that quantity, will be corrected by the sun and air. It is the oxide of iron, which gives the red color to the clay underneath the sand of this field, which, if it were in too great quantities to be brought into immediate contact with the roots of growing plants, might possibly injure them, but the quantity I name, could do no harm. If you had *lime* to apply to your land, the oxide of iron would be converted into a substance similar to plaster, and an immediate benefit would enure to you, in a two-fold sense, first by neutralizing the bad effects of the iron, and secondly, by converting the latter into plaster."

"Who ever *hearn* of iron being in the ground except in lumps hard as stones?"

"Many before you were born."

"But let me proceed. By annually turning up a portion of your clay, instead of having to cultivate an almost barren sand as you now have, in a few years, you would have a good mould, that would resist the influence of the scorching rays of the sun, and your crops would avoid being burnt up by the slight droughts. Your manure, instead of being drawn up and lost through the heat of the sun, will remain in the earth, rot gradually, and as gradually supply your growing crops with food, and you will find that, instead of having to manure every year, once in four years will answer, and particularly if you sow clover and turn that in every second year."

"Why, bless you, clover won't grow here."

"Yes it will, if you do as I tell you: plow deeper, turn up and mix the clay with the sand and lime in your land. If you can't afford to lime, plaster it. A bushel to the acre for a year or two will enable you to raise clover, provided you turn up the clay and get the potash into action."

"Potash! why, there never was either potash or ashes put on this ground, and I'm too far from market to haul it, if I was able to buy it, which I ai'nt."

"I told you before that there was potash in the red clay."

"How did it get there?"

"Providence placed it there, for wise and beneficent purposes, and it remains for you to use it or not, as you may see fit. Plow deeper, I tell you, and you will find potash enough, to add to the fertility of your soil and increase your crops."

"I *reckin* you're a book farmer—you talk so like the strange things *I's hearn* on."

"No, my good sir, I'm not a book farmer, but like yourself, a farmer in a small way, even smaller than you are, yet I do read books, and papers too, on farming, and have read them with delight, and I hope profit, from my earliest recollection. What I see in them that my judgment approves, I practice, if an occasion offers—what I see that I do not approve, I reject—and if you were to take an agricultural paper, both you and your children would profit by it. No man ever yet read anything without gaining by it. The agricultural papers, besides containing the essays and views of *theorists*, have much of the practical experience of *practical* men in them, and by reading them, men become acquainted with the customs and modes of culture of all parts of the world, and surely, with such a field before them, those who do not improve by it must be dull indeed. But I have a few words more with regard to deep plowing, and its effects in promoting the growth of crops. By deepening the bed in which the plants have to grow, you enlarge the pasture of the plants; you enable their rootlets to descend, as well as spread with more facility, and it must be obvious, that by so doing, you greatly improve their chance of growing, as the least difficulty they may experience in searching for food, the better chance will they have of thriving. You say that the red clay beneath the sand, is poisonous to your crops. Be it so. But keeping it in a compact form, you do not render it less injurious, for notwithstanding its hardness, the roots of your corn will penetrate it several feet, so that the objection which you have raised, is *imaginary*, not *real*, and by keeping that stiff clay in an unbroken state, you present it to the roots of your corn, in the very worst and most injurious form that you possibly can,—plow deeper, turn it up to the action of the sun, the air and the rains, and you will soon rid it of its poisonous qualities."

"How deep would you recommend me to plow?"

"Why, I would have you increase your soil two inches each year, until you get at least nine inches in depth."

"Why, bless you, stranger, my plow can't never go that deep, and besides, my horse couldn't never turn up nine inches."

"Get a bigger plow, and put in two horses instead of one. By getting a deep tilth, you will enable your land to absorb a good deal of manure from the atmosphere."

"Who ever *hearn* talk of manure being in the air?"

"I have. There is at all times floating in the air, a substance, which if you can only impart to your soil the power of attracting and absorbing it, you will find that it will add greatly to the fertility of your land. That which escapes from your soil as the manure rots, is the substance I mean, and it is carried away from *you*, to add to the fertility of your neighbor's land, because of its being in a condition to retain it. As the manure in your barn-yard rots, its most enriching properties are carried off by the same process and lost too you. If you wish to prevent such loss, you can do so, by keeping a few inches of dirt of any kind spread over your manure. This will act in a two-fold way, beneficially to your interest. It will prevent the escape of the gaseous substances I have spoken of, while the body of earth above the manure, will become impregnated with the richest of the manure, as decomposition goes on, so that the earth, thus placed on the top, will become as good as any other part of the manure. You have often smelt at a distance from your manure pile, an unpleasant stench, have you not?"

"Yes."

"Well that is what I call a gaseous substance, and the very best and most fertilizing part of the body of your manure pile. It is that which flies off with each current of wind, is lost to you, and enriches the better land of your neighbor, because that land is in a condition to a tract and absorb it, as I have before told you."

"Well, stranger, I don't understand all you have been saying, though I think I'll try to plow a *little* deeper, and burn some of the shells about my house and shore, and see if I can raise clover."

"If you'll do so, you may raise clover and timothy too, and make three bushels of corn where you raise one now. Do you raise any wheat?"

"No; my ground won't grow it."

"Follow my advice, and after you get a good crop of clover, plow that in, seed your field down in wheat, and I'll promise you a good yield, provided you apply ten or twenty bushels of lime to the acre.

"They *tells* me that a hundred bushels is not too much."

"That's very true, but the quantity I have named will answer for several years, and I see no necessity for a man of small means applying a large quantity, when a smaller one will answer present purposes. I believe that lime is not only an alternative, that is an, amender of the soil, but I believe it is also a positive manure, that is, that the plant takes it up as a nutrient."

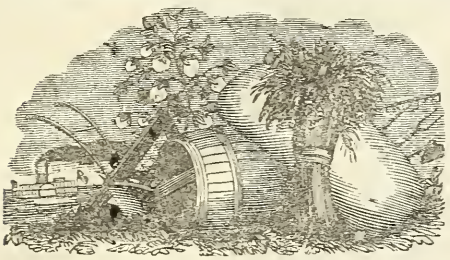
"Nutrient! what is that?"

"A substance that nourishes and encourages the growth of plants."

With this our conversation ended, and we were happy to learn only a few days ago from the individual to whom it was addressed, that he had followed our advice, and had last year, from a field which he was formerly in the habit of getting from two to four barrels of corn to the acre, according to the season, gathered upwards of eight barrels, and that he had grown as fine a crop of clover as he wished to have, when; in former times, when his field was *resting*, nothing but a poverty grass and stinted weeds reared their heads.

—

Subsoil Plowing.—Its efficacy in actually improving the character and depth of soils, where proper tillage has been maintained, has been abundantly proved, and perhaps nowhere more signally than in resuscitation of the sterile lands exhausted by tobacco culture, in Virginia. I speak from my own observation of its wonderful utility in a neighboring county—Fairfax—and have the corroborating testimony of the of the distinguished Judge of that circuit, who declared some time since, that Fairfax, from being proverbially one of the poorest, was fast becoming one of the most fertile counties of Virginia; and this change has been wrought by the immigration of Northern farmers, bringing with them all their agricultural enterprise, and knowledge of what may be properly called the mechanics of agriculture.—*Southern Planter.*



WEDNESDAY, NOVEMBER 13, 1844.

Our Third Volume.—As the time is rapidly approaching for entering upon our third volume, it may not be inappropriate to address a few words to our numerous friends and patrons in reference to the prospect before us, and to advise them of what they may expect from our future efforts in the cause of Southern Agriculture.

Of the past we need not speak, for those whom we address are familiar with the manner in which we have discharged the responsible duty imposed upon us in the conduct of an agricultural journal. It was an experiment, and one which, thus far, has partially succeeded. If our success has not fully equalled our most sanguine expectations, we feel well assured we have laid the foundation upon which a most magnificent and valuable superstructure may and can be successfully reared, for the benefit of our fellow-men. This is indeed an important point gained, and it has been attained too, after encountering, in our progress, almost every species of opposition which could be offered to such an enterprise. We have had to encounter every species of prejudice which could possibly be incident to minds never disposed to regard agriculture as a science, and in which had grown up the most inveterate hostility to everything which savored of "*book farming*," as it has been sneeringly denominated by that class of farmers. Happily for us, and for the well-being of society, during the now near two years in which we have been struggling to excite an interest and to produce an improvement in agricultural science, these clouds which overhung us with such a lowering aspect, are slowly, but certainly, disappearing before the sun-light of truth, sustained and supported by the results of experience and the well-attested experiments of practical men. And now the "Southern Cultivator" is finding its way to the firesides, and has become the companion, of those who but recently would not have admitted it into close intimacy.

Thus much for our continued perseverance, aided, sustained and urged on at every successive step by a few choice, but sterling and unwavering friends. But our object was to speak of the future. Let us unfold then to our friends what are our designs and purposes. Conscious of our own inability to do ample justice to the great cause in which we have embarked as Editor of a Southern agricultural journal, we have been looking around for some one more capable upon whom the responsible duties of Editor of the Southern Cultivator might be appropriately conferred, with a due regard to all the great interests involved in the issue. And we have now the high satisfaction to announce that our efforts have not been in vain. We have secured the services of a gentleman distinguished for his learning and research, who has devoted much of his time and directed the energies of a mind of acknowledged power to the investigation of the science of agriculture, with whose ability as a writer our readers are already familiar. We have, therefore, additional claims upon the kind and favorable consideration of our friends; and we trust that this renewed effort of ours to meet their just expectations will not be permitted to go unrewarded. We therefore throw ourselves upon the kind indulgence and generous liberality of our friends, and ask them to bestir themselves for the circulation and consequent improvement of our paper, for upon them we must rely, as we cannot incur the expense of sending round agents to collect and obtain subscriptions. Every man who reads the paper and desires to see it sustained, has an interest in its success, and in proportion to that interest should he endeavor to extend its circulation, for upon that and that alone are we dependent for remuneration. We do not, then, in consideration of all the great issues at stake, ask too much of every friend of agriculture—aye, of every man in whose bosom pulsates a true patriot's heart—to exert himself for the extension of our circulation.

The new arrangement will be announced in a prospectus, which we shall issue in a few days, in which we shall set forth, distinctly and fully, all the improvements, &c., &c., our friends may anticipate in the forthcoming volume.

Statistics—"*A Georgia Overseer.*"—We regret exceedingly our inability to furnish the statistics asked for by our correspondent "*A Georgia Overseer*"—nor can we refer him to any source from whence he can obtain any portion thereof, save the returns of the census for 1840: and even that will be found very deficient in much that it attempts, with regard to the Statistics of the State.

The exports and imports of Georgia cannot be arrived at with any near approximation to truth, unless by the aid of *guessing* a man should happen to come near. It is true, the exports and imports of Savannah might be obtained, but then we could not ascertain what portion of the exports were the growth of South Carolina, nor could we arrive at what portion of the exports of Charleston and Apalachicola were the growth of Georgia.

Neither do we know how many Agricultural Societies there are in the State, although we are well aware that they are quite too few for the well being of society and the rapid and successful improvement of Agriculture. We have probably two thousand subscribers to the "Southern Cultivator" which ought to be increased to twenty thousand in Georgia alone, besides what our friends in Alabama, South Carolina and Mississippi can and will do for us.

Here there is a wide field for our friends to operate in, and we should like to heer a unanimous resolve go up from every subscriber we have in Georgia, "that each one *would* obtain TEN subscribers to the 'Southern Cultivator.'" What say you to this, friends of the cause? Will you not enter the list of a glorious rivalry in such a noble enterprise? Some—aye, many of you, can obtain ONE HUNDRED. Will you do it?

Texas Cotton Seed.

On our last page will be found the advertisement of our friend John W. Graves, offering to dispose of a very valuable article of cotton seed, to which we refer the reader. It would be needless for us to add any thing to what is there affirmed by the very respectable gentlemen whose statements are appended to the advertisement.—They are all men whose characters for truth and integrity raise them high above any suspicion of countenancing or aiding in the practising of a humbug upon the people, and their statements, therefore deserve, as they will doubtless receive the favorable consideration of the public.

Professorship of Agriculture.—A Professorship of Agriculture has been established in Amherst College, Mass. The Professorship is conferred upon Alonzo Gray, author of "Scientific and Practical Agriculture."

From the Cultivator.

IMPROVING LAND BY GREEN MANURES.

It is believed by some, that the best kind of vegetable growth for turning in, in the form of green manures, is Indian corn sown broadcast. If it be intended to apply lime to the land, it would be well to do so the fall before. Then as early in the spring as circumstances will permit sow corn broadcast, say three or four bushels to the acre, and as soon as it has grown as high as it can be conveniently turned under with a deep working plow, turn it under, and immediately sow another crop in the same way, turning that under as before, but with a medium plow run crossways of the previous furrow. In the middle and southern States, three crops can thus be turned under in one season. It is believed that no system of manuring or renovation, except the heaviest application of stable manure, can compare with this plan in its results. If the land be very poor the first crop will be very light, but light as it may be it will yet add a considerable portion of the elements of vegetable nutrition to the soil; and thus the second crop will be greatly improved, and the third will be all that can be desired. It is believed that in this way four times as much improvement will be effected in one season, as can be by means of clover in three or four years. For this purpose farmers in the north should use the tall kinds of southern corn, as being of more rapid growth and furnishing vastly more matter for the soil.

From the Southern Planter.

THE HAW OR HOOKS.

We had supposed that the absurd and cruel practice of cutting out the haw from the eye of the horse for the purpose of relieving a fancied disease called the hooks, had ceased amongst even the most ignorant of veterinary practitioners; but a gentleman assured us that the plan was frequently resorted to still in the country by those who should know better.

The haw is an expansive membrane with which nature has provided the eye of the horse for the purpose of removing the dust and other impurities that may chance to fall upon that delicate organ, and to cut it off under any circumstances, is not less cruel than ridiculous. This membrane, sympathizing with other diseased parts of the eye, frequently becomes inflamed and swollen, and then it is, that, instead of bathing it with cooling solutions, it is called the *hooks*, and is cut out by ignorant quacks; and thus the horse is deprived of this natural appendage, and is subjected to all the pain and misery that the introduction of foreign substances is calculated to inflict upon that sensitive organ, the eye. We would condemn the man

guilty of this barbarity to stand thirty minutes with a gnat in his eye, his pocket handkerchief stolen, and his hands tied; he would be then able to comprehend the extent of the misery he had inflicted upon an animal oftentimes nobler than himself.

It is true that the bleeding that follows the cutting, sometimes reduces the inflamation and gives some apparent countenance to this barbarous practice—but surely blood letting can be effected under such circumstances upon better terms than the loss of this valuable appendage.

Life's Lesson Should Be.

BY B. HALLECK.

Forget not—regret not
The joys that have fled
Though sweeter and fleeter
Than fresh odors shed
From the jessamine's cup,
Or the bright chalice hid
From the gaze of the sun
'Neath the violet's lid.

Forget not—regret not:
Hope ever should burn
The incense of love
In her funeral urn.
Shedding glory and light
O'er the gems of the past,
By time on the altar
Of memory cast.

Forget not—regret not:
Why should we regret,
While one star remains,
That another has set?
And though all may have faded,
Others brighter by far,
Through the gloom may arise
Than one once worship'd star.

Forget not—regret not:
Life's lesson should be
Like the stars that are hung
O'er the limitless sea,
A guide to our path,
Bright links of the chain,
To lead us and bind us
To virtue again.

AMERICAN NOTIONS.—The Journal of Commerce gives the following as an extract of a letter from Staffordshire, England:

"I wish you would send me the articles named below, at your earliest convenience.—Pray let them be of the best quality as I want them for family use. Say—

7 barrels Newton Pippins.
3 do Duchess County pork, same as the last.
2 do Brown crackers.
1 do Fulton market beef, same as the last.
3 boxes, each 1 large cheese.
1 barrel of cranberries.
4 do flour, with any other "*bonne bouche*" you can think of."

What an uncomfortable situation! A seat on a sofa between two beautiful girls, one with black eyes, jet ringlets, and snowy neck---the other with soft blue eyes, sunny ringlets, red cheeks and lips, both laughing and talking to you at the same time.

MR. AND MRS. CHAPMAN'S
BOARDING AND DAY SCHOOL.
No. 228 BROAD ST. AUGUSTA.

☞ THIS Institution has been under the direction of its present principals for six years, and the success which has attended it has enabled them greatly to increase the facilities it affords for the education of young ladies. Provision is made for thorough instruction in all the departments of female education, from the elementary English studies to the higher branches of literature and science. The next term will commence Tuesday, October 1st. Pupils can enter at any time during the term, and will be charged for the time they are members of the school.

Tuition $3, $12 and $15 per quarter, according to the age and standing of the scholar. Music and French at the usual rates. Board $15 per month.

REFERENCES.—Rev. C. S. Dodd, Rev. W. T. Brantley, Rev. G F. Pierce, Dr. W. H. Turpin, Mr. J. M. Adams, Mr. D. Hand, Augusta; Gov. Crawford, Milledgeville; Dr. E. E. Jones, Madison; Col. Wm. Jones, Warren; Dr. F. George, Jasper; Mr W. B. Munro, Columbus.

POTASH.---A supply of first quality Potash, just received and for sale, whole sale & retail, by [o24-1m] WM. HAINES, Jr

TEXAS COTTON SEED.

THE subscriber offers for sale, Cotton Seed of very superior quality. The original stock was procured in Texas, and cultivated on his plantation in Newton county, for the last three years, with extraordinary success. The yield is much larger, and the quality superior to the Petit Gulph or other kinds of Cotton usually grown in this section of country.

Planters who purchase a supply of the seed may rely upon sufficient increase in product of the first crop to refund the outlay for seed.

Planters who take an interest in improvements of this sort, are referred to the annexed certificates, and the Cotton raised from the seed may be seen at the warehouses of Adams & Hopkins and Clark & Roberts.

JOHN W. GRAVES.

A supply of the above described Cotton Seed is offered for sale at the following places, at five dollars per bushel:

ADAMS & HOPKINS's Warehouse
CLARK & ROBERTS's do.
D'ANTIGNAC & EVANS's do.
HAND & WILLIAMS's Store,
} Augusta.
McKINLEY & MARTIN's Store, Madison.
HILL, MORROW & HILL's Store,
D. DICKSON & Co.'s Store,
} Social Circle

MADISON, October 29, 1844.

Dear Sir—I regret it was not in my power yesterday, when I saw you, to give you any opinion with regard to a small lot of cotton I have growing from seed presented to me last spring by my friend, John W. Graves, Esq. Since then, however, I have been to my plantation and made comparison of it with my crop of cotton, and now take pleasure in saying to you, it is a superior article in point of fineness and length of fibre, containing more lint on the seed, and will yield much more from the same quantity of land planted.

I am respectfully, dear sir,
Your obedient servant,
[Signed] WM. JOHNSTON.

Georgia, Newton County:

I hereby certify that I obtained from John W. Graves, of this county, a sack of Cotton Seed, (which he represented of superior quality introduced from Texas,) which I planted last spring, and find to exceed my most sanguine expectation. I planted it two or three weeks after my other cotton, (which is the Petit Gulph,) and notwithstanding the season was dry and unfavorable throughout the year, (the growing season) yet it is by far the best cotton I ever made. I think by the time it is all gathered, the best part will yield 2000 to 2500 pounds per acre. My neighbors who have seen it are of the same opinion. From the trial I have made, I believe it will yield double as much as my other cotton on land of the same fertility. [Signed] JACKSON HARWELL.
24th October, 1844.

Georgia, Morgan County:

This is to certify that I am neighbor to John T. McNeil, Esq., and that he last spring got a load of Texas Cotton Seed from John W. Graves, Esq., of Newton county, and planted them on what I consider average land of his farm; and from frequent observation of the crop, with his other cotton, (which is the Petit Gulph,) I do believe it will far excel any other cotton I have ever seen raised in this section of country. And I also believe that the staple excels any other I have ever examined, as to fineness and color.

[Signed] JOHN P. EVANS.

This will certify that I acted as overseer for Mr. John T. McNeil for the year 1844. My knowledge of farming induces me to believe that the Texas Cotton, raised by Mr. McNeil this year, is a very superior article, and with me preferable to any other cotton I have ever raised. It is of long and fine staple, and well bolled, and easily picked out, and has withstood a drought this year better than the Petit Gulph Cotton. It is, in a word, a valuable cotton. I have ginned eight bales of the Texas Cotton on Mr. McNeil's *Carver Gin*, and find that it yields one pound of clear cotton from three of seed cotton; and from my experience of thirty years in cotton growing, I have never raised any I think equal to the Texas Cotton.

[Signed] ALLISON KENT.

AUGUSTA, October 30, 1844.

John W. Graves, Esq.:

Dear Sir—Having been called on by you to make a statement in relation to your Texas Cotton, we take pleasure in saying, that for the last two or three years we have received at our warehouse your cotton crops. The quality has invariably proved very superior, both as to color and length of staple. On sale, it has always brought the highest market price. We consider it a very superior article in the cotton line.

Your obedient servants,
ADAMS & HOPKINS.

Mr. John T. McNeil:

Dear Sir—We have received the two bales of Texas Cotton sent by you to us, and take pleasure in saying that in color and length of staple it is superior to anything we have seen; and cheerfully recommend it as such as will always bring the highest market price.

Your obedient servants,
n5-wp&Ctf CLARK & ROBERTS.

BACON'S LARD LAMPS.—A new article, superior to all others for this purpose, emitting a good clear light without smell or smoke, and at an expense, counting Lard at 8 cents a pound, of about a quarter of a cent an hour.

These Lamps have been satisfactorily tested, and are recommended as "just the thing" for the use of planters. and all others who study utility, neatness and economy.

A supply of the above Lamps, with Fillers and Wicks for them. For sale by
HAVILAND, RISLEY & CO.
jy 24-d.c&Cultf

SOUTHERN CULTIVATOR.

VOL. II. AUGUSTA, GA., NOVEMBER 27, 1844. No. 24.

SELECTIONS, EXTRACTS, &c.

From the Tennessee Agriculturist.

TO FARMERS' DAUGHTERS.

I again take up my pen in continuation of the matters on which I last talked to you. I wish to give you a few notions on the education I think most necessary for young ladies,—the effect it should have on the character, or rather the character it should form. If I were to ask you, who of your acquaintances are well educated, you would perhaps specify some whom you consider to be perfectly so. You will say such a one is pleasant and graceful in her manners, sings, plays, and dances in the most approved and newest style,—speaks French, draws, paints and needle-works to perfection, tells of Botany, Chemistry and Philosophy,—knows all the new fashions, has many beaux, and talks to them without the least bashfulness, or blushing. No doubt many of those accomplishments are pleasant and agreeable; and you will perhaps think me disposed to find fault when I tell you a woman may be possessed of them, and even more than you mention, and still, in my opinion, be entirely deficient in true and correct education.

If you inquire in what good education does consist? I answer, that it is not in that course of study alone, that enables a woman to count up her accomplishments, and display them on every possible occasion; but it is that training which improves the heart as well as the mind and manners; in a word, that tends to perfection of character, moral, physical and intellectual. An education that does less than this, is not correct education; it is oftener mis-education. Of what avail are all the accomplishments of earth, if our sex do not with them also possess those gentle and affectionate dispositions, that so much promote the happiness of those with whom they are connected? Do you think it affords much pleasure to a husband that his wife can at times, send forth notes of witching melody, while at others, when no stranger is near to listen, she can address him in the rough tones of anger and contempt? No, her music will never give happiness to his heart, it will never cause it to vibrate with pleasure or tenderness—he listens not to the song of the charmer, charm she never so wisely. Better had it been for her to tune her heart to the soft notes of constant affection, than for her voice to be skilled in the magic notes of song—sweet though they may be.

Then it is one of the most important parts of education that woman learn to govern her temper, to subdue every incorrect feeling and habit, and thus accomplish her *heart*, at the same time, she is improving her mind; and let me say in passing, that by cherishing amiable dispositions the countenance is also greatly beautified, and the voice made better. A soft low voice, coming from a heart full of kindness, is a lovely thing in woman. Let me say to you, that if you have no rule over your spirit, if you cannot school it to bear patiently the ills of life, you are indeed uneducated, even though you may have passed through the whole circle of science. Cleopatra, the ill-fated Queen of Egypt, early applied herself to the acquisition of knowledge, she spoke nine or ten different languages, and possessed every accomplishment in perfection; still she was far from being educated—she could not control her furious and headstrong passions—she could no more rule her spirit, than she could still the ocean's wild flood. Are you not acquainted with some whom you consider educated, who are too useless to attend to the every day duties of life, even if by so doing, they could relieve the cares of a sick or weary mother; you know some, who hate to go about and do good, who take no pleasure in helping a sick neighbor, or in alleviating the sorrows of the afflicted. If a woman's heart prompt her not to do all in her power to soothe the sufferings of her fellow-creatures, the first part of her character is uneducated—her affections are untrained, uncultivated. True education, then, according to my notion, is that training which teaches us to do our duty in life. It teaches us to be meek, humble and useful—never puffs up its possessor with pride, vanity or haughtiness; but enables us to act with ability and prudence in every situation; or, in other words, leads to the formation of pure and good characters.

Before I go farther I would say, I do not wish you to think I am opposed to any of the innocent accomplishments of the day. On the contrary, I consider them calculated to refine and improve the mind. My only objection is, that they receive more attention than matters of greater importance. In many cases, in our part of the country, the fingers receive more training than the heart—the heart that should be the seat of all the noble affections of humanity. I can point out mothers who urge upon their daughters the necessity of practicing on the Piano for hours every day, while by their example they encourage them in a course of deceit and insincerity—but I digress.

There is a part of the education of girls, I think, much neglected, although absolutely necessary; and that all should attend to it, is agreed by most reflecting persons. It is the part that relates to household concerns. I expect you guessed I was coming there soon. Now for those of you who intend never to be married, it does not make so much difference; but for all who have the least idea of being mistresses of families, it is most important you should early learn every thing you wish to practice in after life. You know, in music, without a great deal of practice, you cannot execute with skill and judgment—there will be many false notes, jars and discords. It is just so in the every day music of life; if you do not practice these by times, you will be apt to play out of time, there will be but little melody in your chords, and you will have discords that will last through the whole piece. I know girls who ought not to marry. They are as perfectly ignorant of domestic affairs as children. Some declare they would not know how to bake corn bread; biscuit are entirely above their ken, and as to apple dumplings I should think they are a good deal like George IV of England was. You know it was related of him, that he happened to see one, and was perfectly at a loss to imagine how the apple ever did make its way inside the crust. Some of these girls go to school, study many books, are fond of costly clothing and all fashionable doings; but as to anything useful, it is out of the question. I consider such women totally uneducated; and to those who are so unfortunate as to choose them as partners through life, they are a trouble and a ———but I will not say anything hard about the girls; they would do right if their parents would teach them.

I always advise my acquaintances never to marry girls who boast they cannot do this, or they cannot do that. It so clearly manifests a want of good sense and good education, that there is little prospect of future usefulness.

There is an old bachelor away off down east, talking in the Boston Cultivator about these matters. He advertises for a wife, and describes the requisite qualifications; and, although they are in poetical form, I will give you the old gentleman's cogitations. After other things, he says:

"I'd have—let me see—no, I'd not have a beauty,
For beautiful women are apt to be vain;
Yet, with a small share, I'd think it a duty
To take her, be thankful, and never complain.

Her form must be good—no art to constrain it,
And rather above than below middle size;
A something—it puzzles my brain to explain it—
Like eloquent language must flow from her eyes.

She must be well bred, or I could not respect her;
Good natured and modest, but not very coy;
Her mind well informed—'tis the purified nectar
That sweetens the cup of hymenial joy.

Her home she must love, and domestic employment,
Have practical knowledge of household affairs,
And make it a part of her highest enjoyment
To soften my troubles and lighten my cares.

No fortune I ask; for I've no predilection
For glitter and show, or the pomp of high life;
I wish to be bound in the cords of affection—
And now I have drawn you a sketch of a wife.

If any possess the above requisitions,
And wish to be bound with the conjugal band,
They will please to step forward, (they know the conditions.)
Inquire of the printer—I'm always at hand."

This bachelor, you see, accords with me in my notions of education. He wants a lady possessed of some practical goodness and knowledge; he wishes an assistant in the school of life.

In the same paper, there is another bachelor speaking of the same subject. He says:

"I want to know the inward state
And temper of her mind,
If she will pout, or rage, or fret—
Be gentle, or unkind.

If her discourse is calm and staid,
And judgment rule her life—
Nonsense may charm us in a *maid*,
But never in a *wife*."

From the old bachelors' beginning to speak out so plainly, there must be a scarcity of properly educated ladies. I hope, if you have not formerly thought of these matters, you will turn your attention to them, and strive to train yourselves by acquiring useful knowledge, and by putting it in practice, so that you may be well educated, or what is the same thing, useful and practical women.

I am so tired of writing, it ought to do you some good. If I ever should get rested, perhaps I will talk to you again some of these odd times. Your friend, LUCY.

From the Maine Cultivator.

NATIVE STOCK.

The principle seems now to be very generally recognized, that most cattle degenerate with a change of climate. In examining the statistics and general state of British husbandry at the present day, we shall find that almost every county in that kingdom, has its peculiar stock. This ap-

pears, in most instances, to be the original or "native" stock of the country, improved by judicious selection, or by crosses. So highly esteemed, indeed, is acclimation, that no judicious and discriminating breeder is ever found willing to discard the native stock, but rather prefers it as a *basis* on which to build. Few who are not familiar with the operation of the principles of breeding, as there recognized, can be aware how vast an improvement they are, in a short time, competent to effect. In our own country, cattle raising has never received the attention it deserves. While a few enlightened and enterprising individuals here and there have interested themselves benevolently, in "building up" and improving either by following the rules prescribed by their transatlantic brethren, or by the importation of blood stock from abroad, the stock of a particular locality —the great mass of our farmers have remained comparatively indifferent as to the result of their efforts, and disposed—so tenaciously rooted are certain *old prejudices*—rather to ridicule than approve. Every one is probably aware that so far as the production of good stock is concerned, the farmers of New England are not so much in want of material, as of information and discernment respecting breeders. Our native stock, in its pure state, is peculiarly active and hardy; it has all the benefits of thorough acclimation, and is to the full as capable of symmetrical development, under a judicious and radical system of breeding, as the Durham, the Hereford, or the Devon. There are certain distinctive traits, or points of form with which the experienced breeder associates, correctly, the qualities of activity and vigor in the ox; others which denote the presence of a lactescent propensity in the cow, and others again which bespeak a capacity to convert food into fat. Each of these marks are distinctly impressed, and as incapable of misconstruction by the eye of an experienced observer, as though the several characters they denote or symbolize were written on the animal's hide. It is, however, of little avail that we select our best animals for breeders so long as we persist in the old practice of selecting the best of their offspring for the market. This is an error that we wish greatly to see reformed. There is a degree of inconsistency in it, utterly incompatible with the character of the age.

From the Boston Cultivator.

HEN HOUSE.

Many farmers that keep hens complain that they do not lay in the season of the year when their eggs are in the greatest demand either for consumption in the family or for the market. It is well known that with all the attention that can be bestowed on fowls, that they will not lay so well in cold weather, and hence the high price of eggs at that season; yet much may be done to encourage the production of eggs in the inclement season, and frequently with profit too. Near a good market, one a week each, in the months of November, December and January, will pay for the food usually consumed by hens.

Though in some cases great pains have been taken to make hens lay in cold weather, and without success, yet this is not generally the case. Most persons that wisely manage in this respect, have very good success. Hens should be provided with a warm dry house; it would be well to have the house so warm that water would not freeze in the coldest weather, and when the weather is mild it should be well ventilated.

Last fall we gave what we consider the best plan for a hen house, and for the benefit of many new readers we will now repeat the substance of it in a few words. Make a house 6 or 7 feet high, 10 feet wide, and 10, 20 or 30 feet long, or longer, each length of ten feet forming a section. Divide it lengthwise into three parts of equal width; the centre of which will serve as a walk, and on each side to every ten feet will be a ward, which should be constructed as follows.—About four feet from the ground or the ground floor, make a flooring over the whole ward, excepting about ten inches square at each corner, by the wall, for hens to come up through.

Over this floor put two roosts, about ten or fifteen inches above it, according to the height of the house. On going up on this floor a hen can walk along and take an empty roost, and the manure should be frequently removed from the floor, and a little plaster, ashes, charcoal dust, or sand thrown on it, unless the manure is to be saved for morocco dressers. By adding a small quantity of plaster and charcoal dust to the dung, the ammonia will be fixed and good *guano* may be made. If the manure be not removed, the ammonia will injure the fowl's eyes, when closely confined.

On a line with the walk, and about thirteen inches under the front of the flooring, put a piece of board a few inches wide, with the edge up, extending from one end of the section to the other, for the front of the nests to rest on. On a level with this and one foot back from it put a board, one foot wide, flat side up, extending like the narrow strip from one end of the section to the other. Then make nests of light thin boards, one foot wide from right to left, that there may be ten to a section, and about thirteen inches high, and about the same from front to back.

These nests will rest on the edge of the narrow board, and go back and rest on the wide board an inch or two, then the hens can walk along on the wide board back of the nests, and take any one they please. The nests should be about six or seven inches high, excepting every second one should extend up to the flooring on the sides to form a division. They will be on the upper part at the back part, and the open space in front should be closed with a piece of board, to be removed for the purpose of taking out the eggs.

At each end a short piece of board should extend from the wide board named above, back to the wall, from which the fowls can go up through the flooring. Against the wall in the centre, there should be a piece of board, about fifteen inches from the ground, and from this there should be a piece at each end, extending up slanting to the two short pieces just named; on these slanting pieces there should be some cleats. Then the hens can occupy all the ground, or ground floor, without impediment; they can jump upon the piece by the wall and walk up the ladders and go along the wide board to any nest, or go up through the flooring and to any roost. This gives economy in room as the fowls can occupy the whole ground, then above it the nests, then the flooring and then the roosts, and a free passage to all, and the manure nearly all saved, in the cold season, and removed.

There should be a window in each ward, extending up about as high as the roost, and down to within a foot and a half of the ground. This may be taken out in summer for the purpose of ventilation. The fowls may occupy the walk, or it may be kept neat and clean, by putting laths from the flooring to the roof, and from the nest to the ground. Instead of building a house on purpose, part of a shed or other building may be finished off in this way as a section, or as a single ward, just by taking a place about three feet wide any desirable length. A hen house may be rendered warm by banking it up with common earth, and this can be done in favorable situations with but very little labor.

To make Yellow Butter in Winter.—Put in yolk of eggs just before the butter comes, near the termination of the churning. This has been repeatedly tried, and it makes very fine sweet butter. It is kept by many as a great secret, but its great value requires publicity.—*Cor. Alb. Cult.*

In an experiment in Maryland, in feeding hogs with shelled corn, and the same lot with half the quantity in meal made into mush, it was found that on the mush they increased five pounds more in a given time, than on the raw corn, and their coats were much better.

NEWBERRY AGRICULTURAL SOCIETY.

REPORT ON OATS, RYE, BARLEY AND BUCKWHEAT.

The Chairman of the Committee on Oats, Rye, Barley and Buckwheat, begs leave to Report—

That having been unable to confer with the different members of the Committee, he has perhaps been deprived of embodying in the Report, information that would have been of essential service; that such information as he is able to give for the preparation of these crops, he submits under their respective heads.

The peculiar situation of our climate—the partial failure of our Corn crop will necessarily direct the attention of our planters to these crops; the use which can be made of them renders them peculiarly valuable in the event of a scanty corn crop.

Oats.—This crop has generally been treated with less attention than it deserves. Old worn out lands, considered unfit for any other crop, are usually assigned to it; and it is not at all to be wondered at, that many persons are barely able to save the seed. Many contend that this is all that is wanted—the rest being pastured off by the stock; in this way they receive the full benefit of the crop. It should, however, be made a valuable crop, and better soil should be assigned to it, and better preparation. We have in the cow-pea, a most valuable article for the preparation of our lands for small grain, and as oats usually prosper best on a soil not too finely pulverized, they would receive the full benefit of such a course of preparation; and as in regular rotation of crops, small grain invariably succeeds a corn crop, the cow-pea should be bountifully cultivated with the corn crop, and this turned under as soon as the vines begin to bear; we would thus prepare our lands not only for crops of small grain of every kind, but for every other crop, and the soil instead of being impoverished would continue to improve. By turning under the pea-vines in the fall with a suitable plow, the ground will necessarily be put in excellent preparation to sow your oats, either in the fall or in February, as desired. This could not, under the general system of farming which prevails, be done with the whole crop, but such portion of it as would receive this course of preparation, would amply repay for the extra labor bestowed.

Fall sowing is to be preferred, as the oats are not so liable to be injured by the Spring drought; the yield is greater and the head much better than if sown in the Spring. When, however, it has been deferred until Spring, they should at all events be put in during the month of February. Cotton-seed, if applied then, is of more importance to this crop than to any other. The seed should be carefully plowed in, or if the ground has just been broken up, a heavy iron-toothed harrow would perhaps answer a good purpose in putting the seed to a proper depth. The old adage "dust in your wheat and daub in your oats," is not true with regard to this crop. It is as necessary that the oat crop should be as carefully put in as wheat, for when plowed in wet, a great portion of the seed is buried at such a depth, that the heat and air can never affect it, and it must necessarily perish, or the strength of the grain be greatly impaired by the time it reaches the surface, and before it can recover, it has necessarily to throw out a new series of roots near the surface; during this time it is exposed to the changes of the seasons, whereas, if put in at a suitable depth, the young plants would grow off vigorously. Baron Vogt, of Germany, has fully tested this, and has made a series of experiments to illustrate this important fact. At the same period after the seed were sown, those put in at one inch below the surface, had four healthy blades, while those at three and four inches had two, and at most three sickly leaves. These experiments should convince the most incredulous.

The selection of proper seed is also a subject of much importance. There are, however, some excellent varieties of oats cultivated among us. The Bremen or Potatoe Oats, is

preferred by some, while others prefer the Ruffled. The black and white Tartarian, although not yet cultivated among us, are said to be the best description for the poorest exhausted soils, producing more on those sorts, than any other variety.

Rye has been cultivated perha s as long as any of the varieties of small grain, and its cultivation is becoming a matter of increased importance, as it is found particularly adapted for grazing, furnishing the best early spring pasture we can have recourse to for lambs, young calves, and pigs. Care should be taken not to graze horses, cattle, and hogs upon it while young, and particularly while the ground is wet. It is not so easily pulled up by the roots, and is therefore better adapted to grazing hogs, than any other variety of small grain. If the intention is to pasture, it should invariably be put in during the month of September; it will then be fit to graze in February, at which time it will be particularly valuable, especially for ewes, with early lambs.

In our climate a bushel of seed to the acre is quite sufficient, this will give a good stand, which is of the greatest importance to a crop intended for pasture. For seed it may be sown as late as February. The peculiar aromatic substance, which has long rendered this grain grateful to the invalid, is found to adhere to the brush, and when bolted, it is found necessary to give it flavor to prepare it by making up a decoction, prepared from the bran. The same preparation is necessary for this crop as is advised for the oats. It will grow in dry sandy soils and produce a tolerable crop, and upon the whole it may be considered as preferring sand to clays; it is not so subject to freeze out as oats.

A new variety, which is called the Multicole Rye, has been mentioned during the past year in the Agricultural journals. It is said to be a native of Poland, and that it has been introduced into cultivation in France, with great success. The account given in the London Farmer's Magazine is, that it grows on common soil, suited to the old fashioned rye, but its habits are totally different. By the reports of above thirty Agriculturists, near L'Orient, who have cultivated it during the past two years, it does best in that climate, when sown in June. Its growth is most rapid; two crops of it are cut for hay before July, and by the 15th of August, a grain crop is reaped—the straw is from 8 to 10 feet high, and the head a foot in length. Should this account prove true, it will be of vast importance to us as a grazing crop, as its rapid growth, the length of time necessary to mature it, will render it much better than the common rye.

The Hon. H. L. Ellsworth, Commissioner of the Patent Office, has sent me a small quantity of this seed, which was grown in the District of Columbia, from seed imported from France—the grain is smaller than the common rye, but in his Report it is stated that the grain has improved in size when cultivated here, and in time it may prove valuable to us as a grain crop. Mr. Ellsworth deserves the thanks of our Agriculturists, for the zeal which he has manifested, in collecting valuable seeds for distribution, from all parts of the civilized world. His Report embodies a large amount of useful agricultural information, and he is making renewed exertions to render his report for the next year, still more valuable.

Barley has been cultivated from the earliest antiquity, and was much in use among the Romans, both as food for soldiers and horses. It is, upon the whole, one of the most valuable and important grain crops, which we can cultivate. It is almost invariably a certain crop, as from its early maturity it makes itself from the winter seasons.

For soiling cattle and horses it is superior to any other grain that we can have recourse to. When soiling is the principal object, it is advisable to sow at different times, from the first of October until the last of November; thus furnishing it in succession from the first of March until May. When young, it should be cut off carefully with a keen grass scythe, and raked neat and careful, and if the soil has been made rich, a second cutting can be obtained. It requires a rich loamy soil, and where this cannot be readily obtained, the ground must be made rich by supplying the necessary quantity of stable manure. Ashes is important to this, as it is to every other grain crop. Unless the ground is made rich, you can never expect to succeed with the crop; and as only a few acres are required for the purpose of soiling, even on the largest farm, the ground can readily be manured. Cotton seed applied liberally, is also an excellent manure. As soiling is the principal object, the spot selected for barley should be near, and convenient to the stable and cattle yard. Sow from a bushel to a bushel and a half to the acre. The ground should be deeply broken up, and the seed neatly plowed in; the whole should then be well harrowed, so that the ground is thoroughly and finely pulverized.

Buckwheat.—I regret that I have not been able to procure seed to make any experiments in its culture. From the growth of this plant, its small fibrous roots, and broad leaves, it necessarily draws largely from the moisture of the atmosphere for its subsistence, and will therefore succeed upon the poorest soil, thus affording an excellent green crop to be plowed in for the renovation of old and exhausted soils.

The rapid growth of this plant, its early maturity, would give easily two crops in the same season; for this object, the first should be turned under, as soon as it would furnish the necessary quantity of seed to insure a stand for the second crop. In addition to this, it deserves our attention as a grain. For the small amount consumed in making buckwheat cakes, we are altogether dependent upon the North for our supplies; scarce a bushel is raised in the entire State. When intended for a grain crop, it should be sown broadcast, at the rate of a bushel to the acre. Sow the last of June, and the first of July, and it will be ready to reap in two and a half or three months. It requires no other culture than to harrow in the seed, and if necessary, to pull out the weeds. As the seeds do not all ripen together, care must be taken when a grain crop is desired, to cut it at such time, when the greatest quantity of seed are matured. From the succession of blossoms, this plant affords a rich repast to bees, and on this account is much prized in France and Germany. The seed are considered superior food for poultry. There can be no doubt but that it will succeed admirably in our soil and climate, and I trust the experiment will be tried, both as a grain crop, and as a green crop to turn under for the improvement of our soil.

All which is respectfully submitted.

WM. SUMMER, Chairman.

ON POTATOES, SWEET AND IRISH.

Your Committee met agreeable to appointment, and after conferring together, beg leave to report as follows, viz: For sweet potatoes, we prefer a light grey or sandy soil; if it should be pretty well spent by cultivation, it would be well to cow-pen or manure it broadcast. We prefer hills to ridges, and like to plant pretty large seed, of which we put but one or two in a hill. If the seed is small, there should be two or three put in the hill. When the potatoes are well up, the hills should be scraped down carefully with a hoe, and let lie some ten days or two weeks, then run two furrows with a plow each way across the bottom of the hills, and draw up the loose dirt pretty well to the top of the hill, and so lay them by, as nothing more is necessary in the way of cultivation.

P. S.—Plant about 10th April.

Irish Potatoes.—We prefer the same soil as above stated. Break it up well before you plant. After you have your land well broke up, lay off your rows three feet wide, with a good shovel plow; plant your eyes after having cut your potatoes, about eight inches apart, then fill up your furrow pretty well with light (or loose) stable manure, hog hair, or cotton seed, then throw a little mould on the top with a hoe or plow, then cover the whole patch over about 18 inches deep, with wheat straw, oak leaves, or pine needles, and you have done all that is necessary to make good potatoes, and plenty of them, if the season suits.

All of which is respectfully submitted.

MATTHEW HALL.
JAMES H. MOFFETT.
GEO. BROWN.
ALLEN LESTER.

NEWBERRY AGRICULTURAL SOCIETY.

REPORT ON TURNEPS.

The Chairman of the Committee on Turneps, begs leave to report: That he has conferred with the other members of the Committee, and all agree with him in the same necessary preparation, and the great importance of the Turnep crop.

The soil best adapted to turneps is that of a sandy loam. In favorable seasons very good crops may be raised from any kind of soil; but to insure success sandy land should as a general rule be selected. The ground should be made rich, either by applying the necessary quantity of manure, with a good portion of leached ashes, or by cow-penning. Where this is properly attended to, and the stock regularly pruned from the time seed is gathered, until August, we think it best. The ground should be broken up to a good depth every month, from the time you commence penning your stock, until you are prepared to sow—to get in a good tilth. Every alternate plowing should be crossed, so as effectually to break up every portion, and if rough, a heavy harrow should rapidly pass over it—for it is to be remembered, that the perfect preparation of the soil is of very great importance to the future crop.

The soil should be mellow, deep and fine, before the seed is sown, the roots will grow more readily, they will be better prepared to stand the drought, and the young plants will grow off rapidly. The ground being in good condition, sow broadcast, the necessary quantity of seed, and harrow them in with a light harrow, or with a suitable brush. We have tried both and can discover little or no difference, with this exception, that where the ground is rough, the iron-toothed harrow is to be preferred.

For early use, sow the last of July or first of August. The main crop should, however, be sown about the middle of August. We have observed, when sown earlier than this, and a drought succeeded, that they do not grow off well, and the turneps, even if good seasons should follow, are never of good size and flavor. This is avoided by sowing later, and with proper after-culture, you will have almost invariably a good crop. If sown broadcast, as soon as the plants have leaves an inch broad, hoe and thin them, so as to leave the young plants 10 inches apart, cutting up all the grass and weeds and thinning carefully.

There are many excellent varieties of the turnep, in almost every neighborhood, but when you have to purchase seed, the Swan's Egg, Dale's new Hybrid, White Norfolk, and the large yellow Globe, are the best for table use. For *early* table use, the White Flat Dutch, and the Yellow Stone, are to be preferred.

The Ruta-baga, as a table turnep, is by many preferred during winter, to any other variety. It will continue fit for use more than a month later than any other—and in our genial climate they can be taken from the ground as required for use.

The soil particularly adapted to them is that of a deep sandy loam. The ground should be deeply plowed and put in good order, as that above recommended for common turneps. They should be sown the last of July or first of August, in drills from a foot to eighteen inches; and, as soon as the plants appear of tolerable size, thin them to ten inches in the drill, at the same time give them a good working with the hoe—a second working should follow in two or three weeks, which will usually make the crop.

Care should, however, be taken to draw up the earth around them as they begin to grow above the ground. They have been grown on my place the past season, of fine size; the season, as will be remembered, was a dry and unfavorable one. They possess more nutriment, and are superior to the common turnep for milk cows, imparting little or no flavor to the milk and butter, and as I am satisfied from experience, that they will succeed, I would urge their cultivation upon the members of our Society generally.

Respectfully submitted.

JOHN SUMMER, Chairman.

REPORT ON CATTLE.

The Chairman of the Committee on Cattle, respectfully submits the following Report—

The condition of this portion of our stock, renders it highly important, that a report should annually be read before our Society; and that no neglect should be attributed on his part, he submits such information as he has been able to collect:

When we consider the important part, which cattle form in our domestic economy, we ought to be induced to give them all the care and attention, which they require. Instead of this, we too frequently find that neglect, almost utter neglect, is their lot.

Whoever intends to commence the work of improvement in stock, must first direct his attention to the introduction of a good breed: for any person, who will lay aside prejudice, will perceive at once that the improved breed, which has been introduced among us, is much superior to the common stock of the country. Although in many instances, gross imposition has been practiced upon the community by our stock-driving neighbors, in introducing an inferior breed of cattle, for thorough breds, yet it has been the means, by resorting to the pure blood, of furnishing a cross, which in time, with a judicious course of management, will produce an excellent race of cattle. In recommending a breed for this purpose, I feel confident that for the general improvement of our stock, the full bred short horn will prove the best. It will improve their milking properties, and give them size and an aptitude to fatten more rapidly. It will improve them in the points essential to good beef cattle, giving them lighter heads and necks and better hind quarter—giving them weight in the proper points—points all desirable in meat cattle. A. B. Allen, of New-York, contended, that it was useless to import Ayershires, at a high price, when they could, by breeding their best milkers of the common stock to short horn bulls, produce animals of the same qualities at a trifling cost. It is true we have not as good common stock, as those to which Mr. Allen alludes, as they are remotely descended from the Herefords and Devons; but the experiment has already been commenced by a member of our Society, (Mr. Wm. Summer, of Pomara,) and the calves need only be seen, to be convinced of the great benefit to be expected from this cross. The milk-cow requires a generous supply of suitable food, if you would have her give a regular supply of good, wholesome and nutritious milk, which is all important in making the best quality of butter. Corn meal, shorts, wheat bran, with peas, pumpkins and turneps, in their proper season, furnish the principal food. An important article of food has been almost wholly neglected; I allude to *corn stalks*. There are many stalks in old land which scarcely produce a shoot; these should be gathered when the fodder is usually taken, or before, and cut up on cutting machines, (the improved machines which are made durable, answer an excellent purpose,) and a regular supply given every day: the tops of corn, even after the fodder is taken off, should be fed in this way, as it will give a large quantity of food, which if left to die upon the stalks is wholly lost. In the north, many farmers, who own extensive herds of cattle, keep them stabled during summer, and soil them upon corn stalks, sown expressly for this purpose, either thickly in the drill, or broadcast upon land well prepared: the stalks grow up slender, and when the tassel appears, it is cut of at the ground, and an enormous quantity of food is obtained to the acre. As it is by being sown thickly prevented from sending out shoots, it is rich in saccharine substance, and when fed green, or in a cured state, it furnishes superior food for cattle and horses. The attention of our friends, I trust, need only be directed to these things to give them a fair trial. Pea-vines furnish also an excellent article for soiling. During winter a good turnep crop is all important to cattle of any description. For milch cattle the rutabaga is to be preferred, imparting little or no flavor to the milk; it is moreover rich in nutriment, and with suitable culture, succeeds well in our climate; the turneps should always be washed, before being fed. Shelter is another requisite of importance for the proper rearing and keeping of cattle. Cows require shelter, more so than that of the horse, and at all times during bad weather, it should be within their reach;—under this, in suitable troughs, they should be furnished with salt; suitable racks should be put up to feed them in, and to prevent waste. The calves designed for breeders should have good attention; a regular supply of milk for four months at least should be allowed them; the better to do this they should be early taught to drink from the pail, and by giving them skimmed milk you obtain the cream, and they thrive equally as well, as if suffered to draw from the teat. They should have access to good grass pastures in summer, and rye pastures in winter and Spring, with a portion of good hay and a small quantity of corn meal daily. They should be regularly stabled, and in rainy weather, kept stabled during the day, as the cold rains are very injurious to them while young. Young cattle should have, during winter, a regular supply of turneps, with their dry provender, and by this means they are kept in a much more healthy condition, than if confined to the latter food, and continue to improve through the whole winter, instead of pining away, at the time when green pasturage can no longer be had.

In conclusion we would urge the attention of the members of our Society generally, to the improvement of this branch of their stock, conscious that they will be amply repaid for the care bestowed.

All of which is respectfully submitted.

G. T. SCOTT, Chairman.

REPORT ON SHEEP.

Your Committee on Sheep beg leave to Report:—That they consider the raising of this article of stock, at this period of our political history, of no little importance to the agriculturist in the South. Twenty years ago, when cotton was selling for from 16 to $25 per 100 lbs., and the duty to which imported goods for ordinary wear were subject, was comparatively low, the cultivators of the soil might, they think, with some propriety, have taken from the proceeds of the sale of their cotton crop, a sum sufficient to buy wherewith to clothe themselves and their laborers. Since that period a great change has come over us—such an one too, as renders it necessary that every farmer should, in the opinion of your Committee, cultivate all his resources. The raising of sheep, therefore, in their opinion, should not be neglected, as in their fleece we obtain a raw material which they alone yield, and from which fabrics are manufactured wholly indispensable.

Your Committee have had little or no experience in the improvement, which they have no doubt would result from crosses with the Southdown, Bakewell, Saxony and Merino—and must, therefore, confine their remarks to what they conceive to be the treatment necessary for the native breed of sheep.

At the commencement of cold weather, say middle or last of October, your Committee find it necessary to commence feeding sheep. Sheaf oats, corn and fodder, hay or husks, are good. Green pastures of rye or barley, (if they have been prepared,) will in some degree supercede the necessity of feeding; and they think important to the well doing of sheep. In the absence of green lots they should be permitted to browze about in old fields, about branch sides and in wood pastures in dry weather, in addition to the feed they receive. Ewes, at the time they bring forth their young, should be carefully kept from among hogs, or the lambs will be destroyed by them. Lambs, when young, are quite tender, and should for a few days have special attention, and they with their dams should have shelter provided for them during severe weather. About the middle or last of March, all may be turned to grass. It is thought they are more healthy when kept on short grass, as long grass will frequently produce scours and destroy many.

Shearing should be done about the full moon in May. If shorn earlier, their numbers are liable to be thinned by the effects of cold. Shearing in the fall, they think should not be done. They find the use of tar a pretty good specific against the effects of cold. It may be applied to their noses, and occasionally a small quantity forced down their throats. It will also answer to keep the trough or plank, where they are salted, well smeared with tar, and their salt placed on it. They should be carefully salted once a week the year round.

As a preventive against the depredations of dogs, one of your Committee has adopted the plan of pasturing his sheep with his cattle, and herding them together at night. On the dogs attacking the sheep, they fly to the cattle, and are effectually protected by them.

When the sheep are kept up all summer, they should be frequently shifted from one pasture to another. Sheep are very fond of herbs, such as found in the woods; and which your Committee think, tend to keep them in a healthy condition. A body of woods inclosed with their pasture, might be of service to them.

All of which is respectfully submitted.

P. HAIR, Chairman.

Newberry Dist., (S. C.) Sept. 25.

PLANTING TOO MUCH COTTON.—The following remarks, says the Savannah Republican, from the Hamburg Journal are not a whit the less sensible because briefly and plainly expressed. Our planters would indeed do well to reflect seriously upon this subject. Pursuing their present course of overproducing cotton, they ought not to anticipate anything but short prices and pecuniary embarrassments. The result of the recent election, by increasing the probabilities of annexation, and the enlargement of our cotton producing territory will only tend to aggravate these evils. Depreciation of the prices of both lands and negroes, and ultimate ruin must be the result, unless the difficulty is met, as was suggested, by a diversion of labor. The Editor of the Journal, says:

"Planters of the South, can you raise cotton at present prices? If the great improvement in agriculture of late, and the cheapness of labor, will warrant the pursuit of this employment, well and good; but if, on the contrary, this is not the case, you should reflect on the matter, and cast about for a more suitable investment of labor, capital, and time. You are aware that the western lands, and those of Texas, will repay the planter more at five cents or even less, than our lands will at six cents; and yet you drive on in one long train of toil every year, without counting the cost of these things.

"What then is to be done, you will ask?—Plant less of the staple, raise more provisions, live more at home, improve your lands and stock, and let your farms present an appearance of industry, thrift, and plenty. This is a great country, and all we have to do, is to use exertions in making it beautiful, and ourselves happy and independent, as much as possible, of other countries. Be sure that you have a sufficiency at home, and then send off the surplus. Patronize home industry in all its various branches, and then we shall become a thriving and contented people."

For the Southern Cultivator.

POTATOES.

Mr. Editors—I have been of opinion for several years, that the potatoe crop was too much neglected in this section of country. The crop that I have made this year, has confirmed me in that opinion. I planted a fraction more than two acres. Three-fourths of the land was of second year's tending, and was so full of roots and stumps that we could not prepare it for planting to my satisfaction; but after breaking up the land a time or two, the rows were run off in a horizontal position and beds thrown up with a turning plow, then a hand with a hoe made holes for every eighteen or twenty inches, in which the seed were dropped and covered—these were of the Spanish kind. The land is thin grey soil; growth post-oak and black-jack intermixed with pine. The other fourth of the ground planted, is old grey land, on which cows had been penned. This, and a small part of the fresh land, was planted with yam-slips. (I here remark, that I have found out long since that the richest land is not the best for potatoes.) We hauled home and put away six hundred and forty bushels, and I suppose there were fifty bushels left on the ground for the hogs to get, and we must have dug at least ten bushels previously for table use, &c. At this, my crop from a little over two acres, is seven hundred bushels; but I will take it at 600 bushels, which at 20 cents per bushel, amounts to $120. The same land in corn, under the most favorable seasons and best mode of culture, could not have made more than 80 bushels, that at 38 cents per bushel, (which is the settlement price,) amounts to $30.40. I will allow $10 for the value of labor (*which is more than enough*) expended on the potatoes, more than would have been required on the same land had it been in a corn crop; and will allow $5 for fodder that might have been produced with the corn. At this calculation, there is a balance left in favor of potatoes of $74 60. I may have priced the potatoes too high, but will leave it to the readers of the Southern Cultivator to put their own prices on each article—make their own calculations—draw their own inferences, and come to their own decisions as to the propriety of our planting more potatoes than we have heretofore; and what we do plant, be sure to cultivate well, as they are a crop that is well worth our attention, if they were but to feed our stock on. They will fatten a hog quicker than corn; and for fattening an old ox or cow, I have never found their equal; as a change of food and for milch cows, there is scarcely anything better; and for children, both white and black, they are the most healthy food we can give them.

I am, sir, yours respectfully, &c.,

JOHN FARRAR.

P. S.—I will say to you, that I seeded two small lots in red clover and blue grass, about a year ago. As yet, they do not promise any big things. The clover, on a part of one of the lots, seems to be doing well, which is on the stiffest part of the land. On the softest part, the hot summer caused the most of it to disappear. There is a tolerable good stand of grass. Another year will prove whether it will succeed to much advantage. I have ordered one of *Low's crushers*, from Nashville, Tennessee. You have seen some account of it in the Tennessee Agriculturist; and there was an extract respecting it in the Southern Cultivator some time the past summer. When I get it home and put in operation, I will give you some account of its performance and utility. The present year has proved to me that potatoes do not require as much rain to make a good crop as I have thought they did, as our ground has not been wet but twice since July.

I saw a potatoe the other day, at a friend's, that weighed, in my presence, eight pounds—it was of the red skin kind. A yam of the same size would weigh, I expect, ten or eleven pounds.

STANFORDVILLE, Putnam Co., Ga., November 16, 1844. J. F.

From the Albany Cultivator.

CONTINUANCE OF MILK IN COWS.

Messrs. Editors:—It certainly would be a very great advantage to those who wish to keep a cow or cows, solely for their milk, if any feasible method could be adopted by which cows could be made permanent milkers, or their owners particularly those who live in cities, be saved the trouble and inconvenience of their breeding. There are two ways in which this seems practicable. The first method is to keep the cow in milk, from the bull, by constantly stabling her, after her first and second calf, and in this state, milked regularly and well fed, she will continue to give milk for two or more years. She usually ends, however, by beoming too fat for profit as a milker, her milk gradually failing, and she then goes to the butcher. The large dairies of London, have their cows treated in this manner, and in practice it is found far preferable to the old one, of having them "*come in*" annually.

There is another method of obtaining constant milkers which has been extensively practiced in France, and known to some extent in this country. This is by *spaying the cow* some four or six weeks after calving, and thus by preventing impregnation, securing the cow in milk for several years. In the London Veterinarian may be found a paper by M. Rogere, of Bordeaux, in France, who had for many years been engaged in a series of experiments on this subject, that had been eminently successful. The cows operated upon were of various ages, some quite old. The operation of spaying was followed with a restricted diet to prevent the tendency of inflammation. This had the effect of reducing the quantity of milk for a few days, but the flow soon returned, and continued unaffected for a long time. No danger was incurred by the operation when skilfully performed, and when from age or failure of milk, it became desirable to make beef of the animal, she was found altogether superior for that purpose to the unspayed ones.

In one of the earlier volumes of Ruffin's Farmer's Register may be found a paper on spaying cows or heifers, not only for milk, but for feeding. Mr. Tabb, of Virginia, under whose superintendence the operations were conducted, confirms the representations made of the value of milch cows so operated upon, but thinks it not less essential or important where cows or heifers are to be fed. The following extract is from Mr. Tabb's paper:—"The operation is performed on heifers not intended for milk when they are about a year old, and with the single precaution of keeping them entirely from food or water during twenty-four or thirty-six hours previous—is not attended with the least risk—is performed in the same way, and may be done by any person in the habit of spaying pigs. They go to their food immediately after, and require no attention. We select the most indifferent heifers to spay, which is one way to improve the stock. You increase the size amazingly. They gradually become as large as ordinary oxen—are easily kept—make the finest beef—and as they are not in perfection until six or seven years old, we work them after three or four, to make them gentle, and for that purpose, consider them superior to the ox."

The practice of working milch cows is common in Germany, as appears from the accounts of various travellers in that country; and teams of spayed heifers have carried off prizes at the plowing matches of Agricultural Societies in England. The suggestion made above, by Mr. Tabb, as to the practice of spaying having a good effect in the improvement of stock, is an important one. If the breeders of stock could so far forego the hope of immediate profit, as to be willing to submit all inferior heifers to spaying, it is evident the chances of breeding inferior animals, would diminish rapidly.

Mr. Winn, keeper of an extensive hotel at Natchez, communicated to Judge Peters, of Pa., the result of experiments made by him in spaying cows for the purpose of securing permanent milkers. It appears from the paper as given in the Transactions of the Pennsylvania Agricultural Society that he had two cows, which after being spayed, gave milk constantly for three years each. He preferred cows that had produced two or three calves, as the bags of such would be more capacious, than if spayed after the first calf. I hope that some of our breeders or farmers will try this experiment, since if successful, there can be no doubt such cows would command greatly advanced prices in places where cows are kept for their milk alone.

Ontario, Oct., 1844. A FARMER.

"Much increase is by the strength of the ox." [PROV. XIV. 4.

The following in substance, is Dr. Adam Clarke's *just* commentary on this passage of Holy Writ. The ox deserves more consideration than he usually receives, for the reasons here so correctly given: "The ox is the most profitable of all the beasts used in husbandry. Except merely for speed, he is superior in almost every respect to the horse. 1. He is longer lived. 2. Scarcely liable to any disease. 3. He is steady, and always pulls fair in his gears. 4. He lives, fattens, and maintains his strength on what horses will not eat, and therefore is supported at much less cost. 5. His manure is more profitable. And, 6. When he is worn out in his labor, his flesh is good for the nourishment of man, his horns of great utility, and his hide almost invaluable. It might be added, he is almost no expense in shoeing; and his gears are much less expensive than those of the horse. In all large farms, oxen for the common purposes of labor, are greatly to be preferred to horses. Have but patience with this most patient animal, and you will soon find there is much increase by the strength and labor of the ox."

PRESERVATION OF PUMPKINS.—This fall let every farmer gather as many of his best matured pumpkins as will suffice to supply his stock with a mess daily through the winter, and deposite them carefully in a close and secure repertory, according to the following succinct and definite rules: 1st, lay a stratum of butts of straw from the threshing floor, one foot thick; on this stratum deposite another of pumpkins, and cover them carefully with another layer of straw, and so on to the end of your heap.

In this way, pumpkins may be preserved most of the year, as sweet and fresh as when taken from the field. Try it, friends, and not leave every thing to be discovered by accident, as is the case with experiments in agriculture generally.—*Maine Cultivator.*

"GOING THE HOG" WHOLLY.—An establishment, calculated for the slaughtering and packing of 100,000 of the swinish multitude—we mean those that go on "all fours!"—the present season, have been provided at Madison, Indiana. There will, beyond dispute, be a "great cry there, but precious little wool!"

OBSERVATIONS TO PLANTERS.

The following admirable hints we find addressed to the planters of South Carolina, by a correspondent of the Southern Agriculturist. We wish that they might reach and be heeded by all; for it is certain that the stock of cotton on hand in Europe is fearfully accumulating, and that so long as this process is going on it must continue to fall. There is no escaping this dilemma, and the sooner our southern brethren look this matter in the face and provide for it by a change of system, the better it will be for them. We hope they will take these observations kindly, for they are kindly meant:

"There is a partial if not complete remedy for this evil, which I take the liberty of suggesting through your pages. Let every cotton planter make it a rule and adhere strictly to it, to make no more cotton than he can make clear of his plantation expenses. That is, let him pay all his plantation expenses by other crops, and make only so much cotton as will support his family, pay his debts, and add to his property. Many planters I dare say will answer, that they would be glad to make enough cotton to pay their debts and support their families. This may be true as to some, but in general it would be more pert than true. Even those who are hardest run, purchase corn, salt, negro cloths, &c., with 'cotton' money. I doubt if there is any planter who could not produce enough for market, beside cotton, to pay for all these things, and all plantation expenses. Some are so situated, that they could sell corn alone sufficient for the purpose. Let them increase their corn crop then to that amount and diminish cotton. Others again, if the corn could not be sold, might feed it to stock and sell that. It will bear transportation, and there is a great deal of foreign beef and bacon sold in the cotton region. Wheat and flour in the middle and upper country, could be made to pay these contingencies. Rice will grow at the foot of the mountains and command a good price, and so will tobacco. Many could pay these expenses by cutting timber and making shingles, staves, &c. In short, there are few planters in the whole cotton region, who might not by a little diversion of labor, manage to make what cotton they do, clear of the expense of production, and do so profitably. Let each planter look around him, and see what his resources are. I do not invite him to make his own shoes, hats, blankets, clothes, salt and iron. In most cases, others who are in these lines can make these things and bring them to his door cheaper than he can make them himself. But he can follow the business he understands, or at least is best prepared to carry on, and make something else besides cotton to pay for them.

"I know the folly of recommending any measure to planters, requiring their combined action. I recommend this to each planter for his own individual advantage, as well as for the sake of the whole. While it will diminish the aggregate crop, if it curtails but a bale, it will teach each man to be independent, to a certain extent, of cotton speculators, open his eyes to his own resources, and gradually prepare the way for that change of culture which is inevitable, and at hand, for all those who can not make a heavy bale to the acre. And I would add, that every planter should as speedily as possible reduce his culture to such land only as will make a heavy bale per acre. If he has no such, let him 'make' it—manure will soon do it. Cut down the cotton, increase the corn and pea crop, pen hogs, cattle, and every thing else on straw, muck, weeds, &c., &c, and he will soon have as much land that will raise him a bale to the acre as he wants, if he makes no more cotton than he makes 'clear.'

"I preach no more than I practice. I am a middle-aged planter, and I have nearly always made my cotton crop clear. I have suffered my share in the hard times, and have met, I think, more than my average of losses: yet I kept above board without any stringent economy, mainly because I have paid plantation expenses by selling corn, peas, oats, &c. My expenses have been as heavy as any planter's of the same force, and my land probably as poor; yet I have kept up chiefly, I think, because I did not have to pay them in a lump at the end of the year out of my cotton, which would have left me so small a surplus, that probably I should not have thought it worth taking care of. The balance would have been mere odds and ends, which few know how to make tell. I have made corn, &c., supply my odds and ends of cash, and appropriated them as they came to hand to pay current expenses; and when my cotton came in, I could do something with my little LUMP of CLEAR MONEY. Let me say also, that after next year I shall not plant an acre but will (or at least ought to) yield me 400 lbs. clean cotton. Not one—and not many I trust next year. Yet my land in its best natural condition, will not average half that much. What I adopt for my own good, and experience has proved to me is for the good of every planter, both individually and collectively, I recommend others to try."

From the Massachusetts Plowman.

THE BEST COWS.

You cannot be absolutely certain, when you purchase heifers, that you will have good cows, but by close attention you may acquire the art of judging pretty accurately whether they will prove good. The first point is the udder; if this is not capacious or if it has not the power of becoming so, she will never be a great milker. Then the *color* of the skin is important if you would have rich milk; it should be yellow, or rather a mahogany color; but you want good teats too to draw the milk; large teats, not standing close together are a good sign. These are the most important points.

As to the form of the cow, you will not choose a large head and horns, for it costs too much to support them; nor long legs, to made you hold the pail up from the ground, and to require high fences. Long legs require too much support, they are not good even for travelling. Choose short legged animals whenever you have the choice, whether cows, oxen, horses, or hogs. Choose slender necks and tapering tails; straight backs and broad briskets, for such feed better and are less liable to disease The cow's *body* should be large in comparison with her head and limbs, but it is not an object to keep very large cows and oxen, or horses on our farms, as a general rule. Middle sized cows, and those below it, you will almost always find better milkers than large cows are.

In regard to the color of the body, a red, or yellow, or yellow brindle, is as indicative as any, of a good rich milker. You cannot always determine, by any external marks, whether your heifer will prove a good cow. After trying her one summer, you can tell better, and you can then turn her off for beef if you choose. On purchasing you will have some regard to color as a matter of fancy. Nobody wants a black cow or a white one; and though partly colored cows are endurable, no white man buys a skunk colored horse for his own keeping.

Mild and gentle cows are better than irritable animals, and will be more ready to yield their milk. By close scrutiny you can determine in some degree by the countenance and the motions of the heifer, whether she is naturally docile; yet very much depends on her breaking, her treatment and education during the first season. Vicious treatment will make any animal vicious; still there is a difference of character independent of education. Examine the eye and the face of the heifer; a large mild eye, with a yellow circle or halo around it, is a good indication. The face should not be large, and the bones should all be small in proportion to the body. A large chest is evidence of good lungs and of a hardy animal. The hips should be well spread, for obvious reasons.

By proper attention to selecting and breeding we may just as well have a race of cows that will yield ten pounds of butter per week as five pounds. We know of no neat stock superior to our red Devon cattle; such as we meet with in all parts of New England.

From the Boston Journal.

THE OLIVE.

The olive tree has been prized in all ages in certain regions of the globe. Indeed there is perhaps no tree or vegetable which is more frequently referred to in profane and sacred history, and connected with which are more interesting associations. The dove sent forth by Noah from the ark returned with an olive leaf, by which the patriarch knew that the waters had abated. And it was probably from this circumstance that the olive has ever been regarded as the emblem of peace and of plenty by all civilized nations, heathen or Christian. In the fabled contest between Neptune and Minerva, to decide which should give the name to a new city, each sought for the gift most beneficial to mankind. Neptune brought forward the fiery war horse, but Minerva produced an olive tree, and the palm was awarded to the goddess—and she gave the name of Athens to the new city.

The olive tree appears to have flourished in Syria from time immemorial, and is frequently alluded to in the Holy Scriptures. It is supposed to have been transplanted into Italy during the palmy days of Rome, and was soon cultivated in France and Spain. For ages it has abounded in the south of Europe being much valued by the inhabitants, who use the oil for culinary and other purposes—indeed it constitutes a very important article of food among the inhabitants, and is a well known commodity for commerce.

The olive tree is not remarkable for its beauty or majesty. It usually attains a height of twenty or twenty-five feet, but branches off horizontally a few feet above the ground, like the apple-tree. It bears fruit abundantly every other year, the character of which is well known. The wood is heavy, compact, fine grained and brilliant, and is much used by cabinet makers in the countries where it abounds. It was regarded by the ancients as highly valuable on account of its hardness and durability.

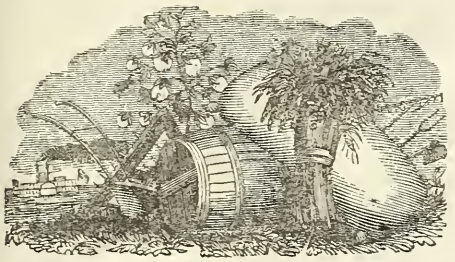
The oil is expressed from the pulp, not from the seed, as is the case with almost all other kinds of oleaginous vegetables. When intended to be picked for exportation, it is gathered while still unripe, and is steeped in the water several days, and afterwards put into a water of lye and barilla. It is then put in bottles or barrels with salt and water, and is exported to other countries, where it is regarded as a luxury, and is believed to be conducive to health and a promoter of digestion.

Whether the olive tree can be made to flourish in any part of the United States to an extent sufficient to give it any considerable value, remains to be seen. Mr. Ellsworth, the Commissioner of Patents, says it may be cultivated in the southern States as far south as the Carolinas. The climate of the southern part of Georgia, of Florida, Alabama and Louisiana would doubtless be suitable for its production, were it not for the very sudden changes from very warm to comparatively very cold weather, which sometimes take place in the winter months. The subject is worthy of attention. The experiment should be fairly tested, and there can be little doubt of its success. Indeed, so far back as the middle of the last century, a band of adventurers from the shores of the Mediterranean planted olive trees in Florida, where they flourished and grew to a large size. We are glad that attention is directed to the subject of increasing the number and the value of useful productions in this country.

Pick carefully all winter apples for sale and for use, and save all other apples for pigs and other farm stock, for which they will be found very valuable in winter.

Feed all fattening animals with perfect regularity—enough, but not too much. Save all your straw well for litter and winter feed.

A writer in the Michigan Farmer, recommends buttermilk for the destruction of lice on cattle.



WEDNESDAY, NOVEMBER 27, 1844.

OUR PROSPECTUS.

FRIENDS AND PATRONS! below we spread before you the Prospectus for our THIRD VOLUME, in which we announce the connection of Mr. JAMES CAMAK, of Athens, as the future Editor of this Journal. His fame as a man of science, and a writer of distinguished ability, who has devoted much time to the science of Agriculture, is too familiar to every Southern man to require commendation of his merits at our hands.

We have, therefore, only a few words to address to the friends of Southern Agricultural Improvement—and we shall not only be brief, but *plain*. To obtain the services of an Editor of such acknowledged ability, we have been compelled to contract a heavy responsibility; and we look to our friends to stand by us in our effort to promote this great and glorious work of Agricultural Reform. The price of subscription is too small to authorise our sending out agents; we therefore rely upon the friends of the work to constitute themselves agents in their respective counties and neighborhoods, to obtain subscribers. To excite a generous rivalry, we have adopted the plan of offering a list of premiums to those who shall obtain the greatest number of subscribers, between now and the first day of March next. This is a novel enterprise at the South, in the history of an Agricultural periodical, but we trust it will be the means of exciting our friends to an effort to extend our circulation. Of course we do not offer the premiums as compensation for services, but simply as testimonials of our gratitude to those who shall win them by their industry and zeal in the cause of Agriculture.

What man would not dwell with an elevated and just pride in after life upon such a souvenir of his efforts in the cause of Southern Agriculture? But we promised to be brief—and we conclude by saying to the planters of the Sonth, Come up to the rescue, and sustain us, if you wish an Agricultural Journal, worthy of your patronage, and the great interest of which it is the organ. Not only subscribe for it yourselves, but urge your neighbors and acquaintances every where to do likewise. Give it, in short, a hearty, zealous, and cordial support, and the work will go on improving in every department and extending its influences into every class of society.

Planters of the South, and friends of Southern Agriculture! we commit the work to your keeping—it will be the organ of your interests and vocations. Will you not sustain it as it may deserve?

☞ We request that those who make an effort to obtain subscribers, will forward their lists as early as possible.

PROSPECTUS

OF THE THIRD VOLUME OF THE

SOUTHERN CULTIVATOR.

IN issuing the Prospectus for the Third Volume of the SOUTHERN CULTIVATOR, the Publishers have the high gratification of announcing to the public, that they have succeeded in engaging the services of

MR. JAMES CAMAK, of Athens, Ga.,

to conduct the Editorial department of the paper. The high reputation of Mr. C. as a gentleman, his acknowledged ability as a writer, his varied acquirements in science, together with the attention which he has always given to Agricultural Science and Improvement, afford the highest guarantee of the future excellence of the work.

To the friends of Agriculture, therefore, throughout the Southern States, we address ourselves, to invite their co-operation in extending our circulation, to enable us to meet the increased expenditure we now make to render our journal worthy the patronage of an intelligent Agricultural community. To you, then, friends of Agriculture, the future destiny of the "Southern Cultivator" is committed, and if you will that it shall be sustained, it will be. You must, then, *every man of you*, "put your shoulders to the wheel" and aid us in an enterprise, which contemplates the melioration of the condition and permanent prosperity of the Agriculturists of the Southern States. Each and all of you can aid us if you will. WILL YOU DO IT?

As we contemplate some slight changes in the work, it may not be improper to advise our friends. It will be published *Monthly*, on the first of each month, (instead of semi-monthly, as heretofore,) and each number will contain SIXTEEN pages of matter, just double the amount in the present form. By this arrangement, the subscriber will have his volume in 12 numbers, and thereby will be subjected to only half the postage he now pays. The first number of the third volume will be issued on the first of January, 1845.

The CASH SYSTEM will be rigidly enforced in all cases; and in no instance will the paper be sent, unless the CASH accompanies the order.

☞ All subscriptions must commence with the volume.

PREMIUMS OFFERED:

The Publishers, desirous of expressing their gratitude in a more tangible form than by mere acknowledgements to their numerous friends, who may make an effort to extend the circulation, offer the following premiums to those who may send them the greatest number of Subscribers to the third volume, up to the first of March next;—

I. For the largest number, not less than 100, a SILVER GOBLET, with appropriate Agricultural designs and inscription, worth..... $25 00

II. For the next largest number, not less than 80, a similar GOBLET, worth..... 20 00

III. For the next largest number not less than 65, a similar GOBLET, worth..... 15 00

IV. For the next largest number, not less than 50, "Loudon's Encyclopedia of Agriculture," worth..... 10 00

V. For the next largest number, not less than 40, "Johnson's Encyclopedia and Dictionary of Rural Affairs," worth..... 5 00

VI. For every man who sends us 30 subscribers, the two back numbers of the Southern Cultivator, handsomely bound.

All communications designed for publication, must be addressed (POST PAID) to JAMES CAMAK, Esq., Athens, Geo.; and those on business, to the Publishers at Augusta,

J. W. & W. S. JONES.

☞ Papers throughout the Southern States, friendly to the cause of Southern Agriculture, will probably advance that cause by giving this Prospectus a few insertions and calling attention thereto.

LARGE YIELD OF COTTON.—On the first of September, we received a letter from A. M. CLIETT, of Houston county, in which he stated that from one acre of land, planted and cultivated, in part, on the plan of Dr. Cloud, he had gathered in the month of August, 1028 pounds of nice seed cotton, and that the stocks were bending under the weight of the unmatured bolls. Mr. C. promised to furnish us at a subsequent time with a more detailed account of the culture, &c., and the yield. We hope he will not omit to do so, when we shall take pleasure in laying them before our readers.

RECIPE FOR MAKING SOFT SOAP.—Soft soap, of excellent quality, is made with 18 pounds of potash, 2 pounds of powdered rosin, and 20 pounds of strained grease. Put the grease into the barrel first, and sprinkle the rosin over it; dissolve the potash in hot water, let it settle, and pour off the solution upon the grease; stir well, and add water to make one barrel of soap; stir it well every day for three or four days, and set it aside for use.

SHEEP.—The Hon. J. S. Skinner, in a letter to the editor of the Prairie Farmer, makes the following remarks:

"I am of opinion that the best sheep walks will at last be found in the hilly and mountainous portions of Virginia, the Carolinas, and Georgia. I was lately in the Middlesex Mills, at Lowell, in which establishment alone they manufacture the fleeces of 1200 sheep a day throughout the year. And I was told by one of the proprietors that they got from the progeny of the Saxon sheep transplanted to Ohio, a staple longer and as fine as that of the original stock. The workers in the factory own $60,000 of the stock."

COOKING FOOD FOR SWINE.—Dr. Lee, in an article on pork making in the last N. G. Farmer, says:—"From some experiments of my own, and considerable research into the published results of the experience of others, I am satisfied that ten bushels of boiled potatoes, thoroughly mixed with the pudding that can be made from three bushels of corn or peas, will make as much pork as twenty bushels of potatoes, and six bushels of corn or peas fed raw."

CORRECTION.—In the last premium offered in our prospectus on the preceding page, we are made to award the two back *numbers* of this paper to every one who shall send us thirty subscribers. It should read the two back *volumes*.

VINEGAR.—A writer in the New Genesee Farmer, gives the following recipe for making vinegar, a barrel of which, according to this mode, will cost but a trifle. His plan is:—Take eight gallons of clear rain water, add three quarts of molasses, put into a good cask, shake well a few times, then add two or three spoonfuls of good yeast, or two yeast cakes. If in summer, place the cask in the sun, if in winter, near the chimney where it may be warm. In ten or fifteen days, add to the liquor a sheet of brown paper, torn in strips, dipped in molasses, and good vinegar will be produced. The paper will in this way form what is called the "mother," or life of vinegar.

POTATOE ONIONS.—The Brockport (N. Y.) Watchman says, that Mr. J. Greenleaf, of that place, has raised this season, 500 bushels of potatoe onions from an acre of land. Some of the largest weighed 1½ lbs. each, and were 17 inches in circumference. This kind of onion is thought by some to be valuable as an early sort—they grow wholly in the ground, like the potatoe. They are said to be mild and palatable.

CURE FOR FOUNDER.—It is said that the seeds of sun-flowers are the best remedy known for the cure of founder in horses. Immediately on discovering that your horse is foundered, mix about a pint of the whole seed in his feed, and it will give a perfect cure.

OVER-EATING APPLES.—The American Agriculturist says that a lump of salæratus of the size of a hen's egg, dissolved in warm water, is a remedy for cattle that have eaten too many apples.

HEMP AND FLAX—We observe by a late Irish paper, says the Louisville Dollar Farmer, that foreign flax is quoted in that country at £42 to £100, Irish flax at £1 15s. to £1 18s. per cwt., and milled flax at £2 12s. to £2 15s. Our object in making this quotation is to show the great advantage we possess in this country in our cheap staple hemp in the manufacture of linen. As has been seen from the extract we lately published from the report of the Russian travelling agent, hemp is used in France for the manufacture of the finest linen, the superiority of the linen being shown by the fact that it is labelled "all hemp." It is further stated that there is machinery of the most perfect kind in Europe for preparing and spinning hemp. Such machinery is also used in Ireland and England. With regard to the article of flax, certainly no country possesses advantages over this. From all these facts, it is obvious that a tempting opportunity is presented in this country for investments in the manufactory of linen both of hemp and flax. A manufacture of flax linen, we see it stated, has been established at Richmond, Va., the proprietor having been induced to transfer his skill from England to the better field in this country. There is no use of trying to invent machinery for preparing and spinning hemp and flax. The machinery is already invented, and there is nothing to do but to import it.

MR. AND MRS. CHAPMAN'S
BOARDING AND DAY SCHOOL.
No. 223 BROAD-ST. AUGUSTA.

☞ THIS Institution has been under the direction of its present principals for six years, and the success which has attended it has enabled them greatly to increase the facilities it affords for the education of young ladies. Provision is made for thorough instruction in all the departments of female education, from the elementary English studies to the higher branches of literature and science. The next term will commence Tuesday, October 1st. Pupils can enter at any time during the term, and will be charged for the time they are members of the school.

Tuition $8, $12 and $15 per quarter, according to the age and standing of the scholar. Music and French at the usual rates. Board $15 per month.

REFERENCES.—Rev. C. S. Dodd, Rev. W. T. Brantley, Rev. G F. Pierce, Dr. W. H. Turpin, Mr. J. M. Adams, Mr. D. Hand, Augusta; Gov. Crawford, Milledgeville; Dr. E. E. Jones, Madison; Col. Wm. Jones, Warren; Dr. F. George Jasper; Mr. W. B. Munro, Columbus.

TEXAS COTTON SEED.

THE subscriber offers for sale, Cotton Seed of very superior quality. The original stock was procured in Texas, and cultivated on his plantation in Newton county, for the last three years, with extraordinary success. The yield is much larger, and the quality superior to the Petit Gulph or other kinds of Cotton usually grown in this section of country.

Planters who purchase a supply of the seed may rely upon sufficient increase in product of the first crop to refund the outlay for seed.

Planters who take an interest in improvements of this sort, are referred to the annexed certificates, and the Cotton raised from the seed may be seen at the warehouses of Adams & Hopkins and Clark & Roberts.

JOHN W. GRAVES.

A supply of the above described Cotton Seed is offered for sale at the following places, at five dollars per bushel:

ADAMS & HOPKINS's Warehouse, CLARK & ROBERTS's do., D'ANTIGNAC & EVANS's do., HAND & WILLIAMS's Store, } Augusta.
McKINLEY & MARTIN's Store, Madison.
HILL, MORROW & HILL's Store, D. DICKSON & Co.'s Store, } Social Circle

MADISON, October 29, 1844.

Dear Sir—I regret it was not in my power yesterday, when I saw you, to give you any opinion with regard to a small lot of cotton I have growing from seed presented to me last spring by my friend, John W. Graves, Esq. Since then, however, I have been to my plantation and made comparison of it with my crop of cotton, and now take pleasure in saying to you, it is a superior article in point of fineness and length of fibre, containing more lint on the seed, and will yield much more from the same quantity of land planted.

I am respectfully, dear sir,
Your obedient servant,
[Signed] WM. JOHNSTON.

Georgia, Newton County:

I hereby certify that I obtained from John W. Graves, of this county, a sack of Cotton Seed, (which he represented of superior quality introduced from Texas,) which I planted last spring, and find to exceed my most sanguine expectation. I planted it two or three weeks after my other cotton, (which is the Petit Gulph,) and notwithstanding the season was dry and unfavorable throughout the year, (the growing season) yet it is by far the best cotton I ever made. I think by the time it is all gathered, the best part will yield 2000 to 2500 pounds per acre. My neighbors who have seen it are of the same opinion. From the trial I have made, I believe it will yield double as much as my other cotton on land of the same fertility. [Signed] JACKSON HARWELL.
24th October, 1844.

Georgia, Morgan County:

This is to certify that I am neighbor to John T. McNeil, Esq., and that he last spring got a load of Texas Cotton Seed from John W. Graves, Esq., of Newton county, and planted them on what I consider average land of his farm; and from frequent observation of the crop, with his other cotton, (which is the Petit Gulph,) I do believe it will far excel any other cotton I have ever seen raised in this section of country. And I also believe that the staple excels any other I have ever examined, as to fineness and color.
[Signed] JOHN P. EVANS.

This will certify that I acted as overseer for Mr. John T. McNeil for the year 1844. My knowledge of farming induces me to believe that the Texas Cotton, raised by Mr. McNeil this year, is a very superior article, and with me preferable to any other cotton I have ever raised. It is of long and fine staple, and well bolled, and easily picked out, and has withstood a drought this year better than the Petit Gulph Cotton. It is, in a word, a valuable cotton. I have ginned eight bales of the Texas Cotton on Mr. McNeil's *Carver Gin*, and find that it yields one pound of clear cotton from three of seed cotton; and from my experience of thirty years in cotton growing, I have never raised any I think equal to the Texas Cotton.
[Signed] ALLISON KENT.

AUGUSTA, October 30, 1844.

John W. Graves, Esq.:

Dear Sir—Having been called on by you to make a statement in relation to your Texas Cotton, we take pleasure in saying, that for the last two or three years we have received at our warehouse your cotton crops. The quality has invariably proved very superior, both as to color and length of staple. On sale, it has always brought the highest market price. We consider it a very superior article in the cotton line.

Your obedient servants,
ADAMS & HOPKINS.

Mr. John T. McNeil:

Dear Sir—We have received the two bales of Texas Cotton sent by you to us, and take pleasure in saying that in color and length of staple it is superior to anything we have seen; and cheerfully recommend it as such as will always bring the highest market price.

Your obedient servants,
n5-wp&Ctf CLARK & ROBERTS.

BACON'S LARD LAMPS.—A new article, superior to all others for this purpose, emitting a good clear light without smell or smoke, and at an expense, counting Lard at 8 cents a pound, of about a quarter of a cent an hour.

These Lamps have been satisfactorily tested, and are recommended as "just the thing" for the use of planters, and all others who study utility, neatness and economy.

A supply of the above Lamps, with Fillers and Wicks for them. For sale by
HAVILAND, RISLEY & CO.

SOUTHERN CULTIVATOR.

VOL. II. AUGUSTA, GA., DECEMBER 11, 1844. No. 25.

ORATION OF THE REV. GEO. F. PIERCE.

Delivered before the Alumni Society of Franklin College, at Athens, in August.

GENTLEMEN OF THE ALUMNI SOCIETY:

Although notified in due season of my appointment to address you, and accepting with good will to serve you to the utmost of my poor ability, yet I have been thrown by the stress of circumstances upon a very hasty preparation. I rely for your indulgence upon the occasion hallowed as it is by the memories of the past, and rich in the associations of the present.

It is a time for grateful joy and hearty congratulation. After the lapse of years, from widely separated sections of our country—from our various fields of labor, usefulness and profit, we meet in the brotherhood of Literature at the shrine of our earliest devotion, to renew the vows of unforgotten friendship and pledge a still fervent loyalty to our time-honored Alma Mater. Who, among us, does not feel the inspiration of the hour—the spell of memory—the gushing of a heart-warm joy, as Athens, though oft unvisited, yet ne'er forgot, rises upon his vision amplified, enlarged, adorned, but still the same in her gray hills—yon rolling stream and these Academic retreats? The thoughts—the hopes of College life, come thronging back upon the bosom with the freshness, the awakening thrill of their first conception! At friendship's altar the past and the present meet, and while yet in the flush of vigorous and aspiring manhood, chastened but not subdued; often defeated, though sometimes triumphant; looking back to the period when hope was strongest in our hearts, and ambition turned every thought in longing anticipation to the spirit-stirring scenes of opening life; the review compels us to feel, even amid the gayety and the gush of this annual convocation, that the glow, the charm, the brilliant dreams of earlier life are dimmed and gone, and that the joy of this resurrection is but an illusion of the memory—the witchery of a gladsome hour, too bright to last, and destined again to the shadow and the grave. Yes, gentlemen, the scenes of former days are gone to return no more. They may revisit us in our musing moods, or rise in mimicry of life at a time like this, and beguile us into forgetfulness for a little season, but the stern events that bestud the track of life, forbid the entertainment—dissolve the panoramic show and stir an almost agonizing consciousness of the flight of years. The sympathies of our Anniversary with emollient power may soften the rugged features of the past, and throw the enchantment of distance over the objects that belong to it; nevertheless, the contrast of early aspirations with subsequent disappointments—the changes of person, location and character—the new relations—the broken ties, must strike painfully upon the spirit; and in the graveyard hush that steals over the bosom, we can hear the foot of Time, the conqueror, as he steps through the silent gloom, enriched by the spoils of which we have been bereaved.

Assembled as we are, to commemorate the days long gone, attracted by the feelings and bound by the ties of a common experience—favored as we have been by Providence and parental kindness, debtors alike to God, our country and our kindred—responsible at every tribunal which Heaven has ordained or society erected, for the adjudication of character, it becomes us to examine ourselves, to ask and answer, what we are?—what we have done?—what we are doing for the elevation and happiness of our kind—the dignity and glory of our country? These inquiries are relevant to the time, the place and the objects of this association. The honest settlement of these questions is demanded by the responsibilities of the future, whether the investigation shall excite the glow of conscious rectitude or overwhelm us with the confusion of undeniable guilt. The shame of personal unworthiness, whether absolute or comparative, is not to be merged in the fact of general delinquency and so bereft of its condemnation; nor will the exultation of generous merit degenerate into vanity by the comparison, but the spirit of honorable rivalry kindled by the contemplation, will rush to retrieve the errors of the past, and though doomed to struggle, is yet destined to conquer. There is a moral beauty, aye, grandeur, in the principle of association—gathering kindred spirits in hallowed fellowship, taking hold upon the strength of numbers, if by the combination of our energies we seek with a noble ambition the more effectually to promote our mutual improvement, intending to consecrate all our acquisitions to the great cause of our country's weal.

Some reflections upon *Georgia—her Literary Institutions* and the *obligations* of *her educated* men may serve to combine utility with entertainment, and will not, I trust, prove an inappropriate or unacceptable offering from your humble speaker. Identified by birth, education and affection, with this my native State, her character is dear to my heart, and her true glory the object of my ambition. One of the old thirteen—canopied by a genial Heaven—irradiated by the light of a glorious Sun—consecrated by the blood of the Revolution—endowed by nature with capabilities vast and varied—circled on the East by a line of coast indented with harbors and bays, inviting to commerce, an interior of forests, hills and vales, fruitful of every good—a mountainous Western section with salubrious air, and mines of unexhausted mineral and metallic wealth, and scenery rich in the beautiful and the sublime, she stands among her sister States, with equals, few; superiors, none. Every effort to enrich and adorn has met a due reward, and the tests of experiment upon her capacities have developed a fecundity of resources wide as her territory and multiplied as her wants. A diamond of the first water, a line of purest light has followed the hand of the lapidary in every attempt to give form and symmetry to her material. In every department of labor or discovery enterprise has received a response which justified the original confidence of the operator, and rebukes the fitful spirit of the people and the selfish legislation of their representatives. While the productions of the soil, the aspects of nature, the hereditary feelings of the citizens, our domestic institutions, and the powerful influences of climate, all concur to foster and mature those developments of mind, best adapted to lofty sentiments—to refinement of taste, and to emancipation from the bondage of vulgar views; yet, is education circumscribed—its value depreciated—its benefits when conferred, prostituted, and the very taste for literature merged in angry contests about politics or in utilitarian schemes, (falsely so called) that besot the understanding and deprave the heart by ministering to the characteristic sin of the nation. We occupy before the world the singularly inconsistent position of boldly asserting equality of rights and privileges under the constitution of the country—denouncing every invasion of our rights, actual or constructive, with vehement passion, and yet tamely submitting to a most inglorious dependence for all the agencies by which taste is to be refined or sentiment cultivated. With equal mind to conceive, and more leisure to execute, we have done and are doing less to augment and diversify the national literature than the inhabitants of almost any other section of this great confederacy. The loftiness of our pretensions and the capabilities of our population considered, and contrasted with our stupid idleness—our disreputable lethargy—our degenerate ambition, we deserve the reproach of our contemporaries, and ought to feel the compunctions of an honest shame. Plied by all the stimulants that ever sprung the activity of sentient beings, yet State pride, Southern spirit, noble emulation, have all been kept in abeyance, and sloth has laid an embargo upon all our faculties and monopolized them for herself; and to disabilities, thus entailed, habit has superadded incurable callousness. Oh, when shall we awake from our oblivious sleep—cast off the wrinkled, withered skin of superannuated folly, and, arrayed in the raiment of intelligence, go forth to redeem the land by restoring her independence?

The sublime exploit of our fathers in establishing our political freedom has entailed upon us the high moral duty of perfecting and perpetuating the blessing. This is to be accomplished, not so much by adorning cities, clearing rivers, extending commerce, building railroads, (important as these may be,) as by the moral and intellectual improvement of the people. In times of peace, this is a primary obligation of government. It is the instinctive dictate of common sense and the oracular decree of enlightened wisdom. But the first want of every people is the last to be supplied by modern statesmen. Engrossed with questions of finance and commerce, of boundaries and treaties, without paltry schemes of personal promotion and party domination, they have made the theory of our government a satire upon its practice. It is a cardinal doctrine of the Republic that the enlightenment of the people is the glory and the guardian of our free institutions; and yet this broad principle, this conservative truth, is left unaided and alone to make its fortune in the world, and like the cures of a charm, works its moral wonders without a visible agency. It is a national amulet—a sainted relic of ancestral patriotism, the jewel of America and the scorn of kings, the pledge of popular dignity and the terror of ambitious demagogues. If action and opinion corresponded, all this, all these it might accomplish, not by magic and mystery, but intelligibly, according to the relations of cause and effect. Considered socially and politically, the principles of virtue and right education are the main elements—the life-giving principles of stability in the institutions of popular government, of honor among the people, and of all that gives amenity and grace to the manners and sentiments of society. But when these great interests are under the ban of legal protection, slighted, stinted, displaced in compliment to ignorant prejudices or party tactics, or turned over as matters of individual responsibility, quite beyond or below the notice of legislatures

and the patronage of the public guardians, then does this narrow-minded, selfish policy strike down the confidence of virtue, invert the laws of social order and surrender morality to the winds and waves, to sink or swim, as Heaven or chance may decree. The system of mutual dependencies which pervades society and links man to man by reciprocal obligations, while it rebukes the self-love which shuts a man within himself and insulates him from all around, yet provides for this strong instinct of our nature by the pleasurable emotions consequent upon liberal sentiments and philanthropic enterprise. They who have but one fixed principle, that of securing their own secular interests, will be ruined by their success, and are doomed to the cheerless desolation of a spirit without sensibilities and of age without friends. And when whole communities yield to the same ignoble impulses and look upon decay without sympathy, or care while their own interests are provided for, and congratulate themselves upon their pre-eminence in all that ennobles our common nature without the inclination to diffuse, then must patriotism mourn the degeneracy of her children, and religion weep the banishment of her principles. Oh! for a generous, expansive, public spirit to bear us away from our selfish centre into the sympathies and activities of a universal charity! Oh! for an enlightened, effective public opinion with trumpet-voice to rally the recreant energies of a dormant people, and muster them in proud array for the work of social regeneration and the redemption of a maltreated land.

Whatever tends to promote the wealth—elicit the enterprise, or advance the moral and intellectual condition of the State, ought to enlist the feelings and the energies of every man worthy to be called a citizen. I like not that sneering philosophy which seeks to extinguish our partialities for our own country by the claims of citizenship wide as the world; and doubt that philanthrophy which vapours about the remote, while it fails to glow with an intensity proportioned to the proximity of its objects. Everything which imparts fertility to the soil, permanency to the population, exultation to the sentiments, fame to the literature, and purity to the morals of the State, ought to levy a contribution upon the praise—the confidence—the co-operation of every man who desires the protection of the laws, or the reputation of his family. But the policy in agriculture has been to exhaust and abandon—in education to neglect and depreciate—in literature to enter into other men's labors. In the absence of positive statutes interdicting the settlement of strangers or compelling the native citizens to remove, or some other extraordinary oppression—if ingenuity had been racked to find ways and means to retard the ratio of population, more efficacious plans could not have been devised than those which have prevailed. Emigration from east to west, as new territory was acquired, and then a change of location to Alabama, or to the valley of the Mississippi, as thriftless husbandry accomplished its work of exhaustion on this side the Chattahoochee, has been the order of the day. The hazardous investment in bubble speculations—the idolatrous devotion to money-making—the prostration of every energy—the sacrifice of feeling—hope—all at the shrine of covetousness (the American Baal) has put a most degrading mockery upon all that prompts to improvement, unless it enrich the divinity of our senseless adoration. The local affections have scarcely had a name, much less a habitation. Houseless wanderers, doomed to dwell upon the wing without a heart to bid them welcome or a roof-tree to give them shelter. The homestead has been as the tent of the Ishmaelite—a lodge for a night, and the occupants wayfarers on pilgrimage to an Eldorado long sought but never found. Architecture (I degrade the word by the connection) of the rudest model has been the highest effort of the farmer, and the floral embellishments on which taste would smile, have been derided as the play-things of girlhood, and the cotton blossom the only flower in nature's garden worth a wise man's regard. The want of every thing like permanency—the shifting migratory character of the people has forestalled progress in every department, and transferred beyond our limits much of the genius, capital and enterprise, to which our loved land was richly entitled, and for the operation and success of which there was amplitude of range and constancy of demand. But with the worst system of husbandry that ever cursed the ground—a spirit of activity that eschewed taste, convenience, comfort, for the sake of treasure, sought and hoarded—preliminary to more rapid accumulation in another region—the home-bred feelings that endear the place of birth and hallow the sepulchres of the dead, resigned to the Indian tribes as unfit to trammel the genius of civilization—what could we expect but hills of flaming clay, fields of dwarfish pines thickly clustered as if to hide the poverty of their origin, and a people deaf and dead to all but the charms of a new country of deeper soil and more abundant gain? It has been too much the custom to charge everything which embarrasses our exertions or defeats our plans to the government, as if no malign influences could arise from any other source in a free country. Whatever may have been the defects of national or state legislation (and on this subject I neither affirm or deny) nothing but the most stupendous fraud of governmental policy, or oppression the most despotic, could have produced the exhaustion of soil that everywhere strikes the traveller's eye, unless there had been some radical wrong in the habits of the people. The evil under which the land groans is social, conventional—part and parcel of the domestic economy of the inhabitants. The haste to be rich, like the first transgression, has not only entailed moral deterioration, but with with baleful breath, mildewed the ground, barrenness its foot print and decay the memento of its travel.

Nothing but downright perversion or wilful abuse of talent could have produced the utter poverty of literature which marks our history. Nothing but niggard or partisan policy could have made education so tardy in its progress or so superficial in its effects. But while the cultivation of the soil, and the support of literature, as to the mode and extent, are mainly dependent upon the will of the people, irrespective of the legislation of the country, it has been the practice of all enlightened goverments to foster by munificent enactments the means and agencies of general information. I speak not now of collegiate education so much as of common school instruction. With ample means to execute, and brilliant examples in other States to guide, we have had a piebald heterogeneous system (if so dignified an appellation may be used to designate it) barren of profit and fruitful only of waste and wrong. The Poor School Fund has been the store on which the lounging *ignoramuses* who aspired to be gentlemen, without the industry to acquire the title or the knowledge to sustain the character, have been permitted to draw, by the license of careless commissioners, while the instruction given has been the mockery of legislative beneficence and a remorseless imposition upon the confiding poor. Without permanent schools, or school-houses; forced to rely upon voluntary associations for the choice of a site and the means to build; the prime movers unpaid, uninterested; the stirring of public spirit scarcely an annual visitation; without specific responsibility to the public in any of their arrangements—nothing but imbecility, mistake and prodigality could have been expected. It is matter of rejoicing, after long years of misrule and defalcation, that the last Legislature began the work of reform. Honored be the man who had the honesty to expose the iniquitous abuse of the public charity—the moral courage to propose taxation for the exigency of the case, and the wisdom to devise a plan of appropriation subject to the control of responsible men. If there is sufficient love of general knowledge to estimate the plan, or vitality enough in the patriotism of the people to apply it, his name shall stand a land-mark on the coast of time, and his monument shall be his country's blessing.

Various causes have combined to retard the progress of higher education. The *ignorant* have laughed to scorn the idea that the knowledge of the languages and of science was a necessary, or even important, qualification for the duties of a citizen in a free country. Nay, many affirm that anything beyond elementary instruction disqualifies for the more common avocations of life; and as the party policy of the country has given to the most ignorant the balance of power, the preponderating influence, they have been too formidable to be assailed in their prejudices, and any attempt at illumination was a covert insult to the dignity of the people and an aristocratic aggression upon the rights of the yeomanry. Legal equality has been made to subserve all the purposes of social merit, and mental elevation and licentious notions of liberty and independence have been allowed to suppress the noblest efforts and defeat the highest instincts of society. Instead of making the laws and regulations of the land, by enlightened legislation and well-directed social influence, the exponents and the guides of popular opinion; popular opinion—mutable, capricious, benighted—has been suffered through a vile subserviency to become a paramount power; a kind of numerical sovereignty, to whose potent, but barbarian will, all must do obeisance. No merely political interests can ever authenticate or give legitimacy to those prejudices which constitute the body-guard of ignorance, and the ready instruments of opposition to moral reform and intellectual elevation. It is the law of the moral world that intelligence shall govern, and the surrender of its heaven-invested rights can never be justified by the paltry triumphs that sometimes reward its degradation. To tremble in the presence of popular clamor, or fly from opposition, is unworthy its high character; but to go over to the enemy, is treason against liberty and order. Brute force may overwhelm it for a season, and its irregular motions and natural insubordinacy defy the authority of reason and the validity of law, but the moral courage sustained by right and a patriotic respect to the general good, that falters not in the assertion of its supremacy, will be sure to gather energy from the conflict and make defeat itself yield the fruits of victory. The cause of education needs bold advocacy in the halls of legislation, by the press and through all the means of access to the public mind. If our prominent men would array themselves upon the subject----defy the cabals of demagogueism----the perversion of sinister intrigues----though they might suffer a temporary eclipse of popularity, yet time would render praise with usury. The tyro politicians who now cater to the vulgar and the base, and like the Arabs of the desert, rush from their obscurity to repel the invasion of light and maintain their lawless rule----rebuked and foiled would retire----leaving wisdom to choose her way and patriotism to direct her journey.

The good have been deterred from patronizing institutions of learning because of the temptations to vice too often clustered about them, and of the facilities for evil that abounded among the youth collected by them. The apprehended deterioration of principle and character, whether justified by the facts or not, was sufficient to stifle the risings of parental ambition, and to doom the boy to bear the disabilities of his sire. I am inclined to think that religious fears and an assumed sense of responsibility have been credited with acts of self-denial that ought rather to have been attributed to a secular policy, cautious of expenditure and glad of an apology to save. With depreciated views of learning and an exaggerated estimate of "the main chance," it is not difficult to perceive how a mind not overwise may be duped by the plausibilities of a mode of reasoning which seems to enthrone Christianity as the presiding guardian of every family movement. If religion gained what education lost by this ill-judging timidity, then should the tongue of re-

buke be dumb and respect be substituted for censure. But when the probable corruption of morals is plead in justification of withholding the means of knowledge, and yet is jeopardied without misgiving for the sake of a lucrative employment, the evidence is clear that the love of gold has been mistaken for the love of purity. The very man who would expose his son without a sigh to the dissipations of a city for a clerkship, or associate him with some senior in depravity for installation in business, would yet dilate with pious horror upon the enticements of sinners in the place of learning; and conscience, betrayed by the sophistry of the basest passion of the human mind, sleeps gently under the conviction, that though the high capabilities of our immortal nature were left to idleness and waste, yet the substantial interests of earth were lodged amid all the securities that wisdom could forecast or prudence provide. Alas! for the sense of responsibility that can be composed to rest by such an arrangement Alas! for the parental tenderness that can be gratified in its dearest wish at so cheap a rate. The good old republican, who would not have his son to grow foppish or proud, by knowing more than his oxen, has done a father's part in teaching him to be selfish and covetous, wiser too, "than seven men who can render a reason" because he could write his name—cast his vote—add figures—knew money when he saw it, and loved it when he got it—was equal to the best in the land according to the declaration of independence and the constitution of the country. This is now the popular doctrine.

The time has been when knowledge, especially that which was exalted and refined, was the monopoly of a few—robed in the garb of mystery—immured in cloisters and dealt to the people with a sparing hand. This system was vindicated by the exclusive patrician maxims that learning diverted the people from the avocations of industry—inspired an impertinent curiosity or a dangerous ambition, and must therefore be restricted. But while these hoary errors of a barbaric age have been abandoned by the master spirits of modern times, they yet linger an incubus and a shame among the class for whose benefit the change has been wrought. But the sun which gilds with his earliest beams the mountain tops, is destined in his upward travel to lift from the valley's bosom the darkness and the mist. The revolution of popular sentiment is slow, in the absence of strongly exciting causes, and in this land of equal privileges, we have trusted too much, perhaps, to the operation of natural agencies. Reason may be free to combat error, but the battle may be fought over our graves, unless we accelerate the conflict; and victory too may linger with her ancient banner, if the friends of truth and light come not to the rescue. Oh! for some plastic power to move upon the face of the waters, that the reign of light might now begin.

(Concluded in our next.)

From the American Farmer.

CONVERSATION ON THE ECONOMY AND MANAGEMENT OF THE FARM.

"How should a farmer act to accumulate and husband the greatest amount of manure?"

"It is difficult to answer a question so vaguely put. Before any one can give anything like a solution approaching to reality, it would be necessary to know the kind of farm, quantity of wood land, of meadow, number and kind of stock, quantity of land in grass, vegetable productions and kind, number and kind of stock, and many other particulars connected with the particular system of farming pursued. It is possible, however, to throw out such general hints, as may serve as a guide, and by which we may arrive at such conclusions, as will enable any careful observing farmer, to make the most of the *materials* within his reach which are convertable into manure?"

"Now, that is what I mean by my question, and I would be obliged if you would give me your views."

"I will do so with pleasure, though before I commence, I wish you to bear in mind, that what I may advance upon the subject, is only to be considered in the light of *opinion*, upon which you are to exercise your own judgment freely. In the first place, a farmer ought to make it an important part of his system of farming, to accumulate everything on his farm susceptible of being converted into manure, and place it in a condition to be availed of without material loss. It has long been my opinion, that every man who works a farm of from two to five hundred acres, would find it to his interest to keep a team and hand constantly engaged in the collection of materials and the formation of manure heaps, as without such economy and forecast, the exhaustion of his land, which is continually going on by the growth of his crops, must impoverish his soil and render it unproductive."

"How could a farmer find employment for a hand and team thus to be occupied? What *materials* are there on a farm, saving the manure of the stock, which could be thus made into the food of plants?"

"There are a hundred sources on every farm, to give occupation in the way I have spoken of—full occupation to a hand and team. Where there is a salt marsh, that of itself would afford ample materials, for there are few richer or more fertilizing substances than marsh mud, if properly combined into composts with lime or marl—the sea-weed of the shores, if compounded with alternate layers of mould and leaves from the woods, or soil of any kind, the layers to be strewed with plaster, will make an excellent and enriching *pie*—the scrapings of the roads, barn and other yards and head-lands, are all excellent to mix with the dung and litter of horses and cattle; but in all such composts, ground plaster or pulverized charcoal should be mixed, layer and layer about, to prevent the escape of the lighter and more volatile parts of the substances while undergoing decomposition; for such parts may be said to be the most valuable—the weeds from the fence corners, lanes and every where else, should be gathered and formed into compost heaps with earth of any kind and plaster. In a word, there are no substances which are susceptible of *rotting* which will not make good manure, some richer than others, but *all good*. The *soap suds* and slops from the kitchen, all water in which the hands and face have been washed, would, if properly husbanded, convert a body of earth sufficient to fertilize two acres, into good manure, in a year. You will perceive that I have opened before you a wild field whence to draw your source of manure."

"But would the benefits justify the expense?"

"Of that there can be no question, and you should not entertain a single doubt. Say that a man could obtain 230 out of the 313 working days, 2000 loads in a year, which is allowing 8 loads per day, that would enable you to manure 100 acres, independent of your usual supply from the stable, barn-yard and pigstyes, each of which acres would, by a moderate calculation, be improved in productiveness at least 33⅓ per cent. Would it not be reasonable to say that each load of this manure would be worth 50 cents? This would be equal to $4 a day for the hire of the hand and team, so that all above the actual cost of their *hire* would be your gain. But your gain is not to be computed by any such contracted rule, as the increased value to be imparted to the soil, in its present and future condition of productiveness, should be taken into consideration, for every 20 loads of such manure would be equivalent to the fertilization of an acre of ground for any period in which it might be required for a rotation of crops, whether that period should be four or six years, provided two of the series be appropriated to grass."

"Have you named all the materials which are convertible into manure?"

"In saying that every thing, or substance, susceptible of *rotting* may be converted into manure, I speak in terms sufficiently broad to comprehend all things, whether vegetable or animal; but as you appear to desire that I should be more particular, I will name a few other articles. The *urine* of the stock of horses and cattle on a farm, where twenty head may be kept, if proper means were taken to prevent its loss, could be rendered equal to the manure of an acre per head. The stalls of the horses should always be kept well strewed with straw, or leaves, or mould and leaves, so as to absorb the liquid voidings, and to prevent the escape of the ammonia, as the decomposition of these voidings might be going on, the stable should be strewed with either plaster or charcoal, daily, and as the stables may be cleaned out, which should be done daily, the mass of manure, litter, &c., should be disposed of on the manure heap, so as to prevent loss from evaporation. This can be done by having earth thrown over each day's manure, as it may be put upon the heap. Again, a few loads of earth should be placed sufficiently near the house to receive the contents of the *chambers*, which earth should be formed into a basin-like form. Each emptying should be covered over with fresh earth, and on that, plaster, or charcoal, be strewed. The importance of this kind of care-taking and economy, may be very readily imagined when I tell you that a gallon of human urine, thus treated, would afford ammonia enough to nurture a bushel of wheat, and if the ammonia were *fixed*, as it would be by the addition of plaster, or charcoal, it would remain in the earth for years, to impart its benefits to successive crops. My own impression is, that if the *liquid* manure made on a farm were to be saved in the way I have pointed out, that it would be worth more to the farmer than all the solid manure made in his stable and barn-yard. And here let me remark, that the *sheds* or *yards* in which cattle may be kept, when brought in from the pastures, should at all times be kept covered with straw or mould and leaves, to prevent the loss of their liquid voidings, as in the case of the horses in the stables, and the same care should be taken to occasionally strew the surface with plaster, or charcoal."

"I think I have heard you say that very stiff clays might be improved by the application of sand. How would you use the sand?"

"I have expressed such an opinion, and I have done so from a practical experience of its benefits. I recollect some years back to have had in cultivation a small lot, about one half of it a piece of as cold, stiff, retentive clay as ever challenged the strength of team, or worried the patience of plowmen. It was so hard, and so retentive of water, that I had to watch the time for its breaking up with more than the power of an eagle's eye, and taking time by the forelock, I had hauled into my cow-yard a hundred loads of sand, which I spread evenly, giving to the centre of the yard a basin-like form; on the top of the sand I spread fifty loads of mould and leaves from the woods, taking care to spread it as I had done the sand, leaving the sides higher than the centre. In this yard my cows were folded and littered through the latter part of fall, winter and spring. Just before the frost sat in, I had the lot plowed up, lapping the furrows so as to expose the greatest surface to the action of the frost. As I desired to receive a crop of millet off the lot the ensuing season, preparatory to laying it down in timothy, I cut three covered drains through it, 2 feet wide and 18 inches deep, on the sides I placed poles, the ends so squared as to fit tight, over these, for want of better materials I laid crosswise, pieces of inch plank, made to fit, placed within half an inch of each other. On these I put grass sods, and then filled up and levelled the top of the drains. In the spring I scraped up and mixed the contents of my cow-yard, adding to the mass 200 bushels of coal ashes, incorporating the whole together. This as soon as the frost was out of the ground, in the spring, I spread over the lot 170 perches in extent, plowed it in as deep as a good wood plow and two horses could plow it; let it remain until the middle of May, when I harrowed, cross-plowed, harrowed again, sowed half a bushel of millet seed, harrowed it in lightly, and finished by rolling. The product on the acre

and ten perchers was 4 tons of good millet hay. In the Agust following, I plowed again to sow timothy seed, and found the soil completely changed in texture, yielding to the share of the plow as does a rich cheese to the knife of the cheeseman. The yield of timothy during the four years that I afterwards remained on the place was always good, ranging from 1½ to 2 tons per acre. From this experiment, I am satisfied that stiff clays can be more lastingly meliorated by sand than by manure, for while the one acts permanently and serves to change the texture of the soil, the other only acts partially, and makes but little if any change upon its *texture*. The sand by cross-plowing becomes intermixed with the clay, disintegrates it, so as to admit the influence of sun and air, aids the water in percolating through the soil, and prevents its remaining to become stagnant to the injury of the roots of the growing plants—and, in a word, renders the soil much easier to work, and more profitable for all the purposes of culture. In connection with this lot, I will remark, that when I put it down in timothy, I spread sixty bushels of lime on it, which was harrowed in with the seed."

"Would you recommend the littering of hog-pens?"

"I am glad you have mentioned this to me, as I should otherwise have forgotten this part of the economy of a farm. I know no part in the arrange nents of the farmer, where more or better manure may be made with as little expense. Whatever is given to the hog-pen, whether coarse tussocks, corn stalks, weeds or mould and leaves from the woods, is sure to be manipulated into excellent fertilizing manure. Ten hogs, penned the year round, if well supplied with materials, would make 60 loads of good manure in that period. The pen should be cleaned out and re-supplied with materials every few weeks. That which may be taken out, should be regularly formed into a heap, made so as to turn the water, and have plaster strewn over it, layer and layer about, which heap would be the better if covered over a few inches deep with earth of some kind, to prevent too rapid decomposition."

"Your plan of saving manure is certainly a good one, but I fear it would prove too costly to be carried into practical effect."

"You act under a delusion as to its effect. Nothing can be said to be "*too costly*" which returns a remunerating interest for the outlay of money. The object of every one who toils is, or should be, to be rewarded by a generous return for the labor bestowed and capital invested, and certainly it is the part of wisdom, to give his labors that direction which promises the most certain and richest rewards. Without a farmer takes the pains to give his lands, in *manure*, a quantity of nutriment equal to that which is annually extracted from it by the growing crops, he must soon expect to see it robbed of its fertility, his products yearly getting less and less, and he becoming poorer and poorer. Even a large farm, if not cultivated with an eye to *improvement*, will make a rich man poor, as it is not the extent of an estate, but its capacity for production which adds to his comforts and wealth. If proper care were taken to convert every thing on a farm into manure that is calculated for it, there is no farmer but might increase its fertility. Nay, a few years devoted in the way I have mentioned, would enable the owner of a poor farm to make it rich, and instead of harvesting 3 or 4 barrels of corn, or 7 or 8 bushels of wheat, he would get 8 barrels or more of corn, and 20 bushels and upwards of wheat. These results have been produced and can be again, by any one who will make up his mind and resolutely pursue the proper course to increase the fertility of his land. But he that crops every year, contents himself with taking every thing out of the land, and putting nothing into it, must expect sooner or later to find it and himself impoverished. It is as necessary to feed the land, as it is to feed the beasts with which it may be tilled, as neither can maintain their strength without food."

ORIGINAL COMMUNICATIONS.

For the Southern Cultivator.

GOOD AND BAD MANAGEMENT.

Mr. Editor:—How happens it, when two young planters set out in life with equal prospects—one having as fair a chance as the other—that we often find one of them steadily pursuing his occupation, and yearly making additions to the stock he commenced with; at the same time that we see the other, though apparently engaged steadily about his plantation concerns, gradually getting behind hand—or if that is not his case, certainly making no additions to his original property?

Some persons maintain that this difference arises from "good luck." I have heard it frequently remarked, such a one "was born with a silver spoon in his mouth," as it seemed he was lucky! Well, we all believe, more or less, in "good luck," and desire it; but an egg must be produced, before a chicken can be hatched!

Others believe in a particular destiny for each one of the human kind—taking the day of the month on which he or she was born—and referring to the book of Proverbs for the reading of that destiny: the 21st chapter for the males, and the 31st for the females.

Now, permit me to assume the position, and undertake to prove it, that the difference in the two cases, as above alluded to, in most instances, arises from good or bad management, in all the various branches connected with the vocation of a planter or farmer.

I shall draw a few simple figures, (*some of which may, perhaps, be thought insignificant,*) not merely for argument sake, but to illustrate the position I have taken. I shall present the two characters in this communication to the readers of the Cultivator, as being both men of families, and in the possession of prudent wives.

First: one will have a place for everything, and everything in its place; while on the plantation of the other, may be seen scarcely anything where it should be. A plow left in one field, a hoe in another, a broken cart or wagon lying by the way-side; and when this, that, or the other tool is wanted, there is a hand or two sent in search of it or them.

One, if he goes in debt at all, keeps a strict account of his indebtedness; keeps his wife advised of all his transactions, consults her in all important affairs, gives her the best opportunities within his power to progress with her household concerns, and assists her in all her undertakings when she is governed by prudence. She, in return, will never be found wanting in returning like favors.

The other goes in debt, and keeps no account thereof; and the larger his debts get to be, taking the greater care to hide the fact from his friends; does not tell his wife frankly of the difficulties he is getting into, nor advises with her as to the best ways and means to extricate himself; and makes contracts to large amounts without consulting his friends or wife.

While one is plowing or hoeing, overlooking his interest, the other is hunting or fishing, or lying at his ease, perhaps asleep under some pleasant shade. One attends in person to all his stock of every kind; the other sends his boy or servant to look after it. One takes, and reads, agricultural papers, and improves thereon; the other cares for none of these things, but pursues the course that will afford him the most ease. One so arranges his affairs as scarcely ever to be under the necessity of borrowing anything; while the other is always compelled to avail himself of that means of supplying himself and family with indispensables, until finally he is forced to borrow almost everything from his more thrifty neighbor. When this kind of business is carried on, in nine cases out of ten, both the borrower and lender is put to inconvenience—the lender rarely bettered.

One prepares his land well for the crop he is about to plant; plants no more than he can tend well; gets out his cotton early; gins and gets it to market early; sells for the best price he can get; and if he owes any debts, pays forthwith—frequently before they are due: while the other neglects his business; gets behind hand in the start; prepares his land badly; plants more land in a crop than he can manage with a bad start, and consequently gets "heels-overhead in the grass;" gets his cotton out late; has it to take to market when the roads are in bad order; neglects to sell; creditors become restless and begin to dun him; finally they become distrustful of him, and order suits; cost and interest are added to the principal of his debts; he frequently begs indulgence in good times until hard times come on him, when it will take two or three times as much property to pay his debts as would have been required at some previous time.

One keeps his fences in good order, is never troubled with his own or neighbors' stock getting into his fields to harrass him at a busy time: while the other neglects the repairing of his; will run the risk of trying another crop with his fences as they are, and by the time his corn is in the ear, cattle break in and cause him a great deal of perplexity and loss of time, to say nothing of the loss he may have sustained in his crop, and the loss of friendship of some good neighbor.

One will make a fair trial to accomplish this, that or the other object. If he fails, he will try again and again, and will not rest satisfied without success. The other will make a partial trial: if he succeeds, he will exult, and wonder why other men have not done thus and so; but if his first trial fails, the object is given up, and he will console himself, in the presence of his neighbor, with the remark, that he had tried hard to have these things, but by bad luck he had failed; he expected to have a fine patch of turnips, but the seed was bad, or if they came up the fowls had ate them up: and so on with other matters, without trying the second time to have the things so much desired.

I might introduce many more items to establish the position I have taken; but believing I have said enough to establish my point, I will come to a close, by further saying, that there are too many planters that are ever procrastinating as to the commencement of this, that or the other improvement, until some of them come within the bounds of an anecdote I heard some years ago, viz:—"A farmer employed a man to

cut a piece of wheat, and gave him three days to do the work. The hireling came on the day appointed, looked at the work he had agreed to do, and said he could do it very easily in two days, and he would therefore go a hunting. He came the next morning, and had another look at the work he had agreed to have done in three days, and concluded that by hard work he could accomplish his task in one day, and he would, therefore, attend to some business he had at a dram-shop. The third morning he came forward and had a careful survey of the field of wheat. His decision was, that there was not a man on earth that could cut that field of wheat in one day, and, therefore, he would not try himself!" I am, dear sir, yours, &c.,

CLOD HOPPER.

For the Southern Cultivator.

CROP OF COTTON IN SOUTH ALABAMA.

MR. EDITOR:—The past season has been favorable for our cotton and provision crops. Our prospects of an abundant production were never more flattering than they were during the last summer, until the appearance of the caterpillar in August. In many fields on the Alabama river, below Claiborne, they were very destructive; having appeared before any part of the crop had matured: and although their progress for a time was very slow, they eventually passed through entire fields, leaving scarcely any trace of vegetation. Fortunately this was not the case generally. There were instances of contiguous plantations, on some of which their ravages were thus marked, and on others very little injury was inflicted by them. Until within a few days past, the weather had been peculiarly favorable for picking. For the last five days it has rained without intermission, and there is, of course, an entire suspension of field work. The loss which must result from this change of the weather, it is apprehended, will be great on the river plantations, as there is yet a considerable portion of the crop not gathered. An inundation of the fields, which we have every reason to anticipate, will destroy all that has not already been secured: and the hopes of the planters, whose crops were not early matured, or who have delayed their picking from other causes, may be thus frustrated From the combination of various causes, the production of the crop will not exceed an average of the last four years: and with the present prices, how small will be the profit of the year's labor! There is but one alternative left to us, and that is, to cultivate less cotton, and direct our attention to the raising of stock, and to domestic manufacture, for our own supply. We must diminish the quantity of cotton for home and foreign markets, and purchase less. No other system but one approaching to a non-intercourse will rescue the Southern planter from the destruction which seems to await his future labors. He must hereafter depend more upon his own resources, and he will be more independent of the labor of others.

Claiborne, Nov. 25, 1844.

☞ "Millions for de-*fence!*" as the nigger said when a bull chased him across a ten acre plantation.

From the American Farmer.

A FARMER REWARDED BY PERSEVERANCE,

We do not recollect to have ever read an account of the good effects of persevering industry, that has given us more pleasure than the following, nor has the degree of pleasure been a little increased, by the reflection that the recipient of the reward belonged to the agricultural class:

EBEN ELSHENDER, THE MOOR FARMER.

There is something so lively and agreeable, and so thoroughly practical, in the following article, which we find in Littell's Living Age, of the 17th of last month, and which is there credited to Chambers's Journal, that we have particular pleasure in transferring it to the Cabinet. It presents to our view a beautiful illustration of the philosophy of farming. The man whose main object is the maintenance of his family, must be careful that his experiments and his enterprises shall eventually prove successful—they should, therefore, be of very limited character, compared with what those may be, of the large capitalist—our friend Eben, for instance. Where the means are abundant, we can scarcely imagine a more pleasing and rational employment than that of improving worn out or impoverished, or naturally repulsive soils. It is a delightful spectacle to observe the man of gloomy mind, roused up to successful action and public usefulness, by an object with which the healthiest and strongest might almost fear to grapple. Reference has occasionally been made in the Cabinet to the advantages of long leases. We are aware that these are less strikingly obvious in this country than in England, where there is not so strong a probability that economy and thrift will soon enable their possessor to make himself his own landlord; and in the case before us, we at once perceive that nothing could have been done without a long protracted engagement.—*Farmer's Cabinet.*

EBENEZER ALEXANDER, or, as he was usually called, Eben Elshender, a native of the north of Scotland, was originally a manufacturer, but not being successful in this line, and falling into low spirits, he went to spend some time at a village where an elder and more prosperous brother had a bleaching establishment, in the hope of recovering the tone of his mind by means of country air and exercise. The place seemed at first sight unlikely to cheer up an invalid of the mind, being situated in a high and sterile district, with northeast exposure and far from all other human haunts; but things turned out much better than might have been expected, and we shall tell how this came about.

Eben, in his wanderings in the neighborhood, was speedily attracted to a hollow in the neighboring moorlands, which might be considered as the only place within several miles, presenting the least charm for the eye—a brook, fringed by a line of willows and a strip of green, formed the simple elements of the scene, and from its situation it had a look of seclusion and warmth. He was led, by what he saw here, to surmise that elevation is not an insuperable difficulty in cultivation, provided there be shelter; and soon becoming convinced of the fact, his active mind in no long time conceived that he might employ himself worse than in endeavoring to clear a little possession for himself, at a nominal rent, out of the neighboring lands. He looked around, but, excepting the few patches in the neighborhood of the village, the region was one either unbroken heath or of moss of great depth, broken into pits, and filled with water even at midsummer. Nothing, therefore, could seem more hopeless. On the left only, as he looked northward, a large flat, lying far beneath him, and black and barren, or covered brown heath, but looking to the sun, seemed to offer the semblance of a cultivated field, and he had determined to visit it. He did so, but found it very unpromising. The surface, though apparently smooth at a distance, was rough and uneven; the soil was either stony and shallow, or a deep quick moss, wet everywhere even in summer, and with no fall by which it might be drained. A rivulet skirted it on the east, and was the natural boundary in that direction; but a swell many feet in height rose on the bank, and closed in the surface of the proposed farm from almost the possibility of being drained; and there were similar embankments on the north and west. Still it was a large surface, not materially uneven; it lay beautifully to the sun, and he could but think that, if drained, and sheltered, and cultivated, here might be an extensive, perhaps, a valuable farm. It would not require deep cuttings, as in moss flows, nor extensive levellings as in very unequal surfaces. He determined to think further.

He spoke of his purpose to no one, but he brooded over it for days, again and again visiting the ground, and last he waited on the agent of the proprietor. Even from him he exacted a promise of secrecy, if nothing should follow upon his offer; and then for a lease of thirty years, offered a shilling an acre for four hundred acres of that unbroken waste, with power to renew his lease for thirty years more, if he should so incline, at five shillings per acre; but with liberty, also, to quit at the end of five years, without being liable in damages from any cause.

Many landlords seem to fancy that though land is of no value in their hands, they have yet a right to be sharers in the profits produced by the intelligence, labor and capital of others, and that they are extremely liberal in forbearing to share for a few years in what had never existed for them, and yet will at the end of those few years, be a valuable inheritance to them and their heirs forever. The landlord in the present case was wiser. He saw that he was about to receive immediately, for a small portion of this moor in cultivation, almost as much as the entire moor brought as an inferior sheep walk, and that at the end of thirty years, it would exceed the original income of the entire possession; while this attempt at cultivation, if successful, would be an example of the utmost value, and might give his village that neighborhood which it so much required. Not only, therefore, was the offer of our friend accepted, but wood for buildings voluntarily offered, and a proper allowance for useful and well-constructed drains.

The villagers were astonished to hear that they were to obtain such a neighbor, but happy even in the hope of it. Enclosed as the place was by banks, which instead of admitting it to be drained, would, if broken, inundate it with water, it looked to them like a huge frying pan, and of course there was not abstaining from some little quiet jokes. This last was indeed the worst aspect of the affair. There was a fall for draining within the farm, but not without it; there was no final outlet. Still, our friend determined on pursuing his experiment: and as a first measure determined to give his possession a good name: he called it *Glen-Eden!*

He next marked off the site for his steading on a very slight but bare and valueless knoll, being desirous at once to sit dry and to spare his good land if there were any. As he felt that nothing would be more apt to encourage him than the comfort of his home, as soon as his turf-cottage was roofed in, he had a floor laid down in one end of it, and raising up slight ribs of wood by the walls, and continuing them overhead, had the whole neatly covered by a thin boarding, which, with the addition of a little carpet and a slight curtain, festooned over his couch—

> A couch ordained a double debt to pay,
> A couch by night, a sofa all the day—

made his end of the tenement seem a palace and enabled him to look on the storm or the sunshine with equal consciousness of snugness and security to health. Good fires soon made the other end very tolerable to his servants; and being washed with lime, though not plastered, it formed a very cheerful temporary residence. He had the rankest of the heath pulled and secured for thatch or fuel, intending to burn the rest on the ground as soon as the ground should be dry. He next laid out the fields, and ordered them to

be cleared of stones—an operation that covered them in some places to the depth of several feet; and finally he set himself to endeavor to lay the land dry.

For this last purpose, at the lowest part of the farm, but where the surrounding wall, as it may be termed, was highest,—and this was on the east,—he ordered a bank of moss to be dug out, and placed in a situation convenient for being dried and burned. In the course of this digging he came upon both stones and clay, treasures of great value in his circumstances; and lest the winter, by filling the pond with water, should render further digging impossible, he pursued his labors with great assiduity. His determination was, that this reservoir should afford him an opportunity of draining the land; and should it prove unequal to this, that a pump or pumps, to be worked by a small windmill, should raise the water to a height enabling him to send it off of his territories. In the mean time, he knew what ridicule the suspicion, even, of such a project would draw upon him, and therefore he gratified inquirers by informing them that he was forming a fish-pond for the residence, and even expected to draw profit from the ice in winter by letting it out for curling, though the game was not then known in that part of Scotland; and the parties, breathing softly, turned from him, and gently lifting up their hands and eyes, departed. Meantime he was intersecting his field, in numerous directions, by drains, leading them into one another, diverging, branching, and every way varying them according to the inequalities of the ground; and after proving their running, carefully filled them with stones taken from the surface, and all tending at last to the general reservoir. Even in winter, the land became drier and drier, and people now began to see the use of the pond. By the return of spring he had effectually drained a large space in front of his residence, and generally prepared it for the operation of the plow. And even in this, by a sort of natural instinct, he differed from the accustomed mode. Aware that oxen draw most gently and steadily, he had secured the temporary use of a strong yoke of these, to be tried in all such portions of the soil as seemed most likely to be capable of being opened up by the plow. People from the village had been engaged to attend at the same time to complete, with the spade and other implements, what the plow might leave imperfectly done, and give him, if possible, a field; and they had by this time so entered into the spirit of the thing, that the attendance was large, and in many cases gratuitous. He had no lime for the present; but he had been scavenger to the villages during the winter, and he had secured all the runnings from his own cattle in a great tank. He now set to burning, in close kilns all the turf he had been able to accumulate during the summer; and between these and the refuse of the few cattle for which he had been able to find food, he was enabled to plow and manure some twenty acres of land, which he sowed and planted with the usual crops, accompanying all the white crops with sown grass. To complete his experiment, he had procured a cask to carry out the runnings of his stables, &c., and having placed it on a cart, and fitted it with a tail-box pierced with holes, such as is used for watering streets and roads, he, as a last operation, sprinkled this liquor, so far as it would go, over the ground that had been dressed with ashes, at night, that no portion of it might be wasted by the sun; and so closed the labors of the first spring.

Science had not then discovered to us what is now known to be true, that the terms good and bad land, as generally understood, are expressions without meaning, as almost every species of land requires some culture to make it productive; and by suitable means much may be made of almost any kind of land. Neither was it then known, as it now is, what are the precise ingredients necessary to the production of the various crops, and to which the soil is a mere matrix or receiver; and that burned earth or lime, and ammonia or the runnings of stable and other usual manures, contain many of these ingredients. But by instinct or accident, by reasoning from what he had noticed, or heard, or read, and perhaps so far experimenting without much knowledge or expectation, our friend had hit upon many things now known to be useful, and the result surprised many. Not only was there no failure in the crops of Glen-Eden,—as they now began seriously to call it,—but they were rich and beautiful. The oats, standing upon moss of great depth, but drained—and that but for the draining and manure, would not have borne a green leaf—were as luxuriant as if the depth of the moss had been the cause of their excellence. The other soils, lately so thin and dead, were now deep and dry, and bearing excellent barley, with a flush of clover about its roots. Potatoes, the gift of warm and distant regions were flourishing in their little beds on this lately cold and barren moor, as if it had been their native and appropriate soil, and, in short, industry and intelligence had in a few months triumphed over the ignorance and neglect of centuries.

Till these things became apparent, however, our experimenter kept in the shade. He had dismissed all his workers, except his hind, whom he termed his "resident manager," and his wife, who was his sole servant, and a Gibeonite of a boy, for looking after his sheep. As the crops began to show themselves, the hind urged upon him the beauty of their appearance, and the almost certain success of his experiment, and consequently the duty of resuming operations. According to all appearances, his first crop would more than pay the expense that would give him a permanent and valuable possession; and as Eben inclined to this opinion, he determined to resume. As a proper preparative to this, he allowed his mother and sisters to visit him, and though they were shocked with the outward aspect of his residence, a black and careless looking turf-hut, in the midst of a comparative wild, and guarded by a pet sheep and her lambs, that, as they approached, patted the ground in a very menacing manner, yet when they entered it, and found the servant cheerfully preparing a meal in one end, while in the other was a little parlor such as any gentleman might inhabit with zest and enjoyment, they were not only surprised and pleased, but would gladly have protracted their visit, and were delighted to understand that they were speedily to join him.

Of course, from greater experience he rose to greater success. Even his laborers worked more cheerfully from seeing the success of what he had done. Moss that had hitherto seemed a nuisance, was to him a treasure, and husbanded accordingly: and stones that, above ground, were such an encumbrance, were, when planted in drains, of the utmost value. He became perfectly happy in his labor of improving, and almost regretted to think that one day it must have an end. Thirty years have passed since these operations were begun; the barren moor has been reclaimed into a valuable and productive farm, the once barren and rugged banks that impeded its draining have long been turned into boundaries covered with herbage of the softest texture, and crowned with woods at once an ornament and a shelter, and that being to be paid for, will render their owner rich. Even the deep and unsightly pool, that first assisted in laying the dry land, has been surrounded and screened by willows and alders, both useful in their way; and the numbers of ducks and geese constantly breeding on its borders and floating on its bosom, must add no inconsiderable item to the profits of the farm. Where the first damp and disheartening turf shed was erected, there are now warm and substantial offices, and fronting all, and flanked by garden walls, and bet hind them trees, stands a farm-house, in its first days a cottage, but always the seat of plain abundance, and now of every comfort and generous hospitality. Though in a climate not very genial, *it* is always warm; and from various flowering shrubs spread over it, seldom without flowers. It is the cherished residence of an industrious, ingenious, and very worthy man.

Many, stimulated by his success, soon followed his example, though on a less extensive scale; but the unpromising wild of thirty years ago, is now a sheltered, cultivated, and comparatively fertile spot, and the abode of many industrious and contented families.

A Beautiful Incident.

Messrs. Editors.—The following incident occurred a few weeks since in a village in one of the Southern counties of our state. It was a warm Sabbath afternoon, and the doors of the village church were thrown open to let in the balmy air from the fields without. The congregration had assembled and, while the minister was reading his first hymn, a beautiful dove entered the door and came walking up the main aisle.

Such a visitor drew of course universal attention. But as the choir arose to sing, he seemed startled, and lifting himself on his wings, alighted on the stove pipe above him, where he sat bending his glossy neck and turning his head so as to catch the harmony as it swelled through the Temple of God. Whether it was the chorus of voices or the full-toned notes of the organ that captivated him I cannot tell; but he sat the perfect picture of earnest attention till the music ceased.

Waiting a moment as if to hear the strain commence again, he started from his perch and sailed to the top of the organ, where he furled his pinion and sat and looked down on the audience. The young clergyman arose to pray. He is distinguished for his earnestness and fervour of his invocation, and as he stood with his hands around the Bible which lay clapsed before him, humbly beseeching the Father of all Good to send his Holy Spirit down, that beautiful bird pitched from its resting place on the organ, and sailing down on level wing the whole length of the church, perched on the Bible directly between the hands of the clergyman.

It was merely a natural occurrence, but how beautiful the picture. There stood the messenger of God with face toward heaven pleading for heaven's blessing—the Bible before him, around which his hands were reverently clasped, while on it stood that beautiful and innocent dove. The three thus together formed a group full of interest, and symbolizing all that is dear to man. The Word of God was before the people, with God's chosen emblem upon it, and God's herald clasping them both as he prayed.

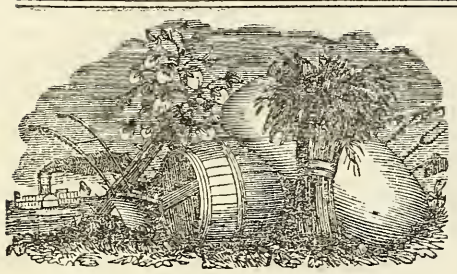
What wonder if a superstitious feeling ran through the house as the people watched the dove, the emblem of innocence and purity and the Divine Spirit itself—standing on the Bible and looking gently on them. Beautiful bird, it centered for a time the affections of all on it; and he who could have injured it there, would have injured hundreds of hearts at the same time. The pressure of its tiny feet was no sacrilege there, for the expression of its soft eye was innocence and love.

The clergyman, feeling the presence of the bird, and fearing it might distract the attention of his hearers, gently passed his hand over the Bible. The dove, unstartled, merely hopped over on the cushion, where it sat till prayer was ended. It then rose and sailed away. In former times the dove would have been regarded as a spiritual visitant from the unseen world, sent on a special mission in answer to prayer, and awakened feelings of awe and reverence.

To us it was only a natural but unusual occurrence, awaking simply the sentiment of beauty. It was a new and accidental figure introduced suddenly into a beautiful picture, giving greater harmony and perfection to what we deemed perfect before. There was no religion in it, but it was full of beauty. H.

Employment is necessary to man: if agreeable, it is a pleasure; if useful, a happiness.

Agriculture is the art of raising crops—husbandry the art of preserving and expending them.



WEDNESDAY, DECEMBER 11, 1844.

☞ We earnestly request all our friends who take an interest in obtaining subscribers for us, to send in the names of all they have obtained by the first of January.

Rev. Geo. F. Pierce's Oration.—We feel especial pleasure in inviting the attention of every reader, and particularly every father who is rearing a son, to the admirable oration pronounced by the Rev. Geo. F. Pierce, before the Alumni Society of Franklin College, at Athens, in August last, the first portion of which will be found in this number. Having, in common with a large auditory, distinguished for its intelligence and good taste, heard, with infinite pleasure, this admirable production delivered, and deeming it particularly well adapted to the correction of an evil which has become quite too common in the present day, we immediately called upon the accomplished author to obtain a copy for publication in the "Cultivator," to which he assented, in the event that the society before whom it was delivered, and by whom a resolution for its publication had been adopted, should not determine to give it a different direction. We have, therefore, the high gratification of giving it to our readers, to whom we are persuaded we could not render a more acceptable service. It would indeed be superfluous for us to add any comment upon its merits, even did our space permit, for the distinguished reputation of the author will secure for it a general perusal, and we cannot but hope that its wholesome and well digested truths will be productive of much and permanent good to the rising generation, and consequently to the future prosperity of Georgia.

☞ We are informed by Mr. Edward Wilson, of this county, says the Highland (N. C.) Messenger, that he raised, during the past summer, from one seed, twenty-one pumpkins that averaged twenty-five pounds each! Beat it who can!

☞ The N. O. Picayune of the 27th ultimo says:—Green corn, in the ear, is selling in the Mobile market. A gentleman of Stockton, Baldwin county, Ala., has raised two crops of corn this season; the second of which was in full maturity some ten or twelve days since.

Judge dairy cows more by the quantity of cream than of the milk they produce; milk is always thinner soon after calving, afterwards it gradually becomes thicker.

Guinea fowls are a preservative against hawks with poultry; and they lay more eggs than hens.

PROSPECTUS
OF THE THIRD VOLUME OF THE
SOUTHERN CULTIVATOR.

In issuing the Prospectus for the Third Volume of the Southern Cultivator, the Publishers have the high gratification of announcing to the public, that they have succeeded in engaging the services of

MR. JAMES CAMAK, of Athens, Ga.,

to conduct the Editorial department of the paper. The high reputation of Mr. C. as a gentleman, his acknowledged ability as a writer, his varied acquirements in science, together with the attention which he has always given to Agricultural Science and Improvement, afford the highest guarantee of the future excellence of the work.

To the friends of Agriculture, therefore, throughout the Southern States, we address ourselves, to invite their co-operation in extending our circulation, to enable us to meet the increased expenditure we now make to render our journal worthy the patronage of an intelligent Agricultural community. To you, then, friends of Agriculture, the future destiny of the 'Southern Cultivator" is committed, and if you will that it shall be sustained, it will be. You must, then, *every man of you*, "put your shoulders to the wheel" and aid us in an enterprise, which contemplates the melioration of the condition and permanent prosperity of the Agriculturists of the Southern States. Each and all of you can aid us if you will. Will you do it?

As we contemplate some slight changes in the work, it may not be improper to advise our friends. It will be published *Monthly*, on the first of each month, (instead of semi-monthly, as heretofore,) and each number will contain SIXTEEN pages of matter, just double the amount in the present form. By this arrangement, the subscriber will have his volume in 12 numbers, and thereby will be subjected to only half the postage he now pays. The first number of the third volume will be issued on the first of January, 1845.

TERMS.

ONE COPY,..... $1.00
SIX COPIES,..... 5.00
TWENTY-FIVE COPIES,..... 20.00
ONE HUNDRED COPIES,..... 75.00

The CASH SYSTEM will be rigidly enforced in all cases; and in no instance will the paper be sent, unless the CASH accompanies the order.

☞ All subscriptions must commence with the volume.

PREMIUMS OFFERED.

The Publishers, desirous of expressing their gratitude in a more tangible form than by mere acknowledgements to their numerous friends, who may make an effort to extend the circulation, offer the following premiums to those who may send them the greatest number of Subscribers to the third volume, up to the first of March next:—

I. For the largest number, not less than 100, a Silver Goblet, with appropriate Agricultural designs and inscription, worth..... $25 00
II. For the next largest number, not less than 80, a similar Goblet, worth..... 20 00
III. For the next largest number not less than 65, a similar Goblet, worth..... 15 00
IV. For the next largest number, not less than 50, "Loudon's Encyclopedia of Agriculture," worth..... 10 00
V. For the next largest number, not less than 40, "Johnson's Encyclopedia and Dictionary of Rural Affairs," worth..... 5 00
VI. For every man who sends us 30 subscribers, the two back volumes of the Southern Cultivator, handsomely bound.

All communications designed for publication, must be addressed (post paid) to James Camak, Esq., Athens, Geo.; and those on business, to the Publishers at Augusta,

J. W. & W. S. JONES.

☞ Papers throughout the Southern States, friendly to the cause of Southern Agriculture, will probably advance that cause by giving this Prospectus a few insertions and calling attention thereto.

MANAGEMENT OF HENS.

The Kennebeck (Me.) Agricultural Society having offered premiums for the best management of fowls, two competitors gave statements of their mode; and as they contain useful hints, we copy that of Mr. Child so far as relates to management, and that of Mr. Martin entire. To the former the first, and to the latter the second, premium was awarded.

From the Statement of James L. Child.

My hens laid nearly as well during the winter as in the warm weather. Their habitation was warm, and so constructed as to bring them to the ground, where they found at all times, a good supply of old plastering, ashes, pulverized oyster shells, charcoal, fresh water, once or twice a week beef liver, or some other kind of meat. I feed chiefly upon baked or boiled potatoes, giving their food to them warm in the morning and at night, occasionally dealing to them a little corn or oats, and giving them all crumbs, and skins, and fragments of the cooked vegetables. To prevent their being infested with lice, about once a fortnight I mixed in dough so as to discolor it, a quantity of flour of brimstone, which is a sure preventive as well as remedy, and may be safely given in small quantities to young chickens, for the same purpose.

It will be seen from my mode of keeping my hens, which average about 25 and 3 roosters, through the winter, that I cannot give the precise cost of keeping, but I am satisfied that potatoes may be given as a general food, and fowls kept cheaper in this mode than in any other—and they will always be ready for the spit, if not stinted in quantity. I find my fowls fat at all seasons.

I estimate that my hens afford me from their eggs, without regard to their meat, a clear profit of 50 per cent. I confine them to their yard, hen-house and barn cellar during gardening, and to their house and cellar in the winter, and think with that degree of confinement, they lay better than they do when allowed to wander at large. Hen-houses and roosts should be kept neat, and often whitewashed, and their nests should always have half an inch or more of ashes or lime on the bottom, under the hay. Broken or rotten eggs should never be allowed to remain in the nests. Dirty water should not be given them. To do well, they require pure water, and all their food fresh and uninjured from taint or fermentation. I estimate that during the year, (deducting the time of their moulting, and inclination to set,) I have got daily, one half as many eggs as I have had laying hens.

Every family can, with very little trouble, with their flock of a dozen hens, have fresh eggs in plenty, during the whole year, say in all, 2,000, and 100 full grown chickens; and of all the animals domesticated for the use of man, (if such be the fact,) the hen is capable of yielding the greatest profit to the owner. It is a pleasant recreation to feed and tend a bevy of laying hens.

Care should be taken to change roosters often, as otherwise the best variety in the world will run out, and cease to be profitable from breeding in: and I feel great confidence that much improvement may be made by due attention to crossing, and in this way some of the evils from breeding be averted. I have stated that I give my fowls meat: this is indispensable if they are not allowed to go at large. If corn is fed out, it should be soaked, and 15 bushels is a fair yearly allowance for 12 hens and a rooster. But they should always have food by them, and after they have become habituated to find enough at all times in the trough, they take but a few kernels at a time, except just before retiring to roost, when they will take nearly a spoonful into their crops; but if they are scantily or irregularly fed, they will greedily snatch up a whole crop full at a time, and stop laying, and not unfrequently engender some fatal disease.

Statement of JESSE MARTIN.

To the Kennebec County Agricultural Society:

GENTLEMEN:—The following is my method of keeping poultry, for which, I want your premium, if you consider me entitled to it:

My family of hens consists of twenty in number, exclusive of old king chanticleer, who rules the roost, cracks the day, and calls to operations. They are of the genuine old fashioned Kennebec breed, which live by eating, and lay for amusement; they generally pay all my *bills* by using their own. I have a room for them in one corner of my barn, warm and comfortable, well furnished with roosts, nests, &c., where all their operations are carried on, although I give them liberty to go into other parts of the barn, and occasionally the liberty of the yard, which is equal in size to that of any honest man or rogue, who has taken the benefit of the poor debtor's oath. Their bill of fare consists of a constant supply of corn in cold weather, and another dish, which they prefer, is made of boiled potatoes mashed up fine, and scalded meal or bran, in the proportion of three quarts of the former to one of the latter. In the summer the corn is shortened, and more of the hen-pudding (as we call it) is supplied. In order that the shell department of the business may be carried on to advantage, I supply them with lime and pounded bricks. I kept my account current with them, between the first of January last and the thirty-first day of July, inclusive, in which time I received two hundred and fifteen dozen of eggs: these I have sold for eleven cents per dozen, making $23 65
Estimated cost of corn and potatoes, 5 00

Balance in favor of hen family, $18 65

From this sum, take the interest of the capital invested, cost of lime, brick dust, and attendance, and you can have the profits of the brood.

☞ The Sugar crop in Louisiana is estimated at 185,000 to 200,000 hogsheads the present year.

BUCKWHEAT CAKES.—As this is the season for buckwheat cakes, the following recipe will at this time be valuable to those who are fond of them; a friend, who has tried the experiment, says it makes decidedly better cakes with half the trouble necessary in the usual mode of raising them with yeast.

To three pints of buckwheat flour, mixed into a batter, add one tea spoonful of carbonate of soda dissolved in water; and one do. of tartaric acid dissolved in like manner; first apply the carbonate, stir the batter well, and then put in the acid; thus the use of yeast is entirely superseded, and cakes "as light as a feather" are insured. One great advantage is that the batter is ready for baking as soon as it is made.

The foregoing is a very excellent *recipe* for "spoiling a batch of batter," or turning out "cakes," upon which chippings from a respectable leather apron would be quite an improvement! The man who started the *recipe* must have had strange notions about the "lightness of a feather." Cakes, such as he recommends, would give an ostrich the nightmare!

PRINCE'S
Linnæan Botanic Garden and Nurseries,
FLUSHING, L. I., NEAR NEW YORK.

THE New Descriptive Catalogues (which have cost over $700) of the TREES, PLANTS, and SEEDS at this Establishment, will be sent gratis to every *post paid* applicant by addressing

WILLIAM R. PRINCE & CO.
Flushing, Dec. 4, 1844.

TEXAS COTTON SEED.

THE subscriber offers for sale, Cotton Seed of very superior quality. The original stock was procured in Texas, and cultivated on his plantation in Newton county, for the last three years, with extraordinary success. The yield is much larger, and the quality superior to the Petit Gulph or other kinds of Cotton usually grown in this section of country.

Planters who purchase a supply of the seed may rely upon sufficient increase in product of the first crop to refund the outlay for seed.

Planters who take an interest in improvements of this sort, are referred to the annexed certificates, and the Cotton raised from the seed may be seen at the warehouses of Adams & Hopkins and Clark & Roberts.

JOHN W. GRAVES.

A supply of the above described Cotton Seed is offered for sale at the following places, at five dollars per bushel:

ADAMS & HOPKINS's Warehouse, CLARK & ROBERTS's do., D'ANTIGNAC & EVANS's do., HAND & WILLIAMS's Store, } Augusta.
McKINLEY & MARTIN's Store, Madison.
HILL, MORROW & HILL's Store, D. DICKSON & Co.'s Store, } Social Circle

MADISON, October 29, 1844.

Dear Sir—I regret it was not in my power yesterday, when I saw you, to give you any opinion with regard to a small lot of cotton I have growing from seed presented to me last spring by my friend, John W. Graves, Esq. Since then, however, I have been to my plantation and made comparison of it with my crop of cotton, and now take pleasure in saying to you, it is a superior article in point of fineness and length of fibre, containing more lint on the seed, and will yield much more from the same quantity of land planted.

I am respectfully, dear sir,
Your obedient servant,
[Signed] WM. JOHNSTON.

Georgia, Newton County:

I hereby certify that I obtained from John W. Graves, of this county, a sack of Cotton Seed, (which he represented of superior quality introduced from Texas,) which I planted last spring, and find to exceed my most sanguine expectation. I planted it two or three weeks after my other cotton, (which is the Petit Gulph,) and notwithstanding the season was dry and unfavorable throughout the year, (the growing season) yet it is by far the best cotton I ever made. I think by the time it is all gathered, the best part will yield 2000 to 2500 pounds per acre. My neighbors who have seen it are of the same opinion. From the trial I have made, I believe it will yield double as much as my other cotton on land of the same fertility. [Signed] JACKSON HARWELL.
24th October, 1844.

Georgia, Morgan County:

This is to certify that I am neighbor to John T McNeil, Esq., and that he last spring got a load of Texas Cotton Seed from John W. Graves, Esq., of Newton county, and planted them on what I consider average land of his farm; and from frequent observation of the crop, with his other cotton, (which is the Petit Gulph,) I do believe it will far excel any other cotton I have ever seen raised in this section of country. And I also believe that the staple excels any other I have ever examined, as to fineness and color.

[Signed] JOHN P. EVANS.

This will certify that I acted as overseer for Mr. John T. McNeil for the year 1844. My knowledge of farming induces me to believe that the Texas Cotton, raised by Mr. McNeil this year, is a very superior article, and with me preferable to any other cotton I have ever raised. It is of long and fine staple, and well bolled, and easily picked out, and has withstood a drought this year better than the Petit Gulph Cotton. It is, in a word, a valuable cotton. I have ginned eight bales of the Texas Cotton on Mr. McNeil's *Carver Gin*, and find that it yields one pound of clear cotton from three of seed cotton; and from my experience of thirty years in cotton growing, I have never raised any I think equal to the Texas Cotton.

[Signed] ALLISON KENT.

AUGUSTA, October 30, 1844.

John W. Graves, Esq.:

Dear Sir—Having been called on by you to make a statement in relation to your Texas Cotton, we take pleasure in saying, that for the last two or three years we have received at our warehouse your cotton crops. The quality has invariably proved very superior, both as to color and length of staple. On sale, it has always brought the highest market price. We consider it a very superior article in the cotton line.

Your obedient servants,
ADAMS & HOPKINS.

Mr. John T. McNeil:

Dear Sir—We have received the two bales of Texas Cotton sent by you to us, and take pleasure in saying that in color and length of staple it is superior to anything we have seen; and cheerfully recommend it as such as will always bring the highest market price.

Your obedient servants,
n5-wp&Ctf CLARK & ROBERTS.

BACON'S LARD LAMPS.—A new article, superior to all others for this purpose, emitting a good clear light without smell or smoke, and at an expense, counting Lard at 8 cents a pound, of about a quarter of a cent an hour.

These Lamps have been satisfactorily tested, and are recommended as "just the thing" for the use of planters. and all others who study utility, neatness and economy.

A supply of the above Lamps, with Fillers and Wicks for them. For sale by
HAVILAND, RISLEY & CO.

SOUTHERN CULTIVATOR.

VOL. II. AUGUSTA, GA., DECEMBER 25, 1844. No. 26.

ORATION OF THE REV. GEO. F. PIERCE.

Delivered before the Alumni Society of Franklin College, at Athens, in August.

(Concluded.)

Another circumstance of disastrous results in the past and of evil omen for the future, is the fact that anything but a learned profession (a wretched misnomer by the way) has been considered quite beneath the dignity of a college-bred man. I mean no disrespect to lawyers or doctors, when I say that the supply largely exceeds the demand; and the want of employment among the incumbents of these departments of society has gone far towards reducing the honor of manual labor, and of giving respectability to idleness. The capital of a country is but accumulated labor, and he who adds nothing to the stock, by the toil of his head or his hands—whatever may have been his educational privileges, or whatever may be his nominal fellowship with the diligent, the honorable and the useful—is yet the abettor (involuntarily perhaps) of impoverishment and vice.

There is but little difference, however, between a life of inactivity by preference, and the choice of a profession which dooms one, by obvious and invincible causes, to lie hand-locked and idle for years, and often for life. In the absence of stern discipline and of high self-sustaining integrity, the moral dangers that ambush this theatre of action are fearful, and sometimes take captive those best furnished for the war. The arrest of ambition—the forestalling of hope—the stagnation of enterprise, engender discontent and despondency, and drive their despairing victim into the apathy of a heart, from which the spirit of honorable independence has fled, or hurry him out of the insufferable calm into the rapids of dissipation, on whose dark waters he is destined to roll a hapless and dismantled wreck. Oh! how many ethereal spirits, appointed of heaven to enlighten and bless the world, have been quenched in the noxious vapors, exhaled from the bogs and fens of public life, or fanned into fury, have become firebrands to set society in a blaze. O! how many a grey head has gone down with sorrow to the grave, mourning the extinction of life's last and fondest hope in the inebriate folly of a reckless son. Many a staid observer of society has preferred to retain his boy in the sheltered lowliness of life's humblest walks, rather than adventure him upon the high places, where the rushing storm sweeps anon and the heaving surge dashes upon the base, nor yet in vain. The professions, I know, ought to be filled; but they need not be gorged. These necessary appendages to every well-ordered and well-provided community, ought not to be converted into enclosures to rear "lilies that neither toil or spin," or made to bear the odium of having admitted to honorary membership a set of men who, born to dig, are yet not ashamed to spunge. I have no respect for an idle man—the country has none—and the curse of education and of colleges has been that by the inconsistent policy of the people they have been made the apparent patrons of an order of things hostile to the primary virtues of personal independence and self-sustaining labor. But this cup of mischief is nearly full. The law of necessity is beginning to be felt. Thanks to our slandered climate—our crystal waters—the temperance reformation and the blessed Providence ruling over all, the crowd of M. D.'s who scatter themselves over the land, have time to review their studies and enjoy their title by virtue of their diploma, rather than by the abundance of their gains. The law, with its locust swarm, yields but little—except to the veterans of the bar—dooms the young candidates for fees and honors to the fate of a coroner, who derives his living from the accidents of field and flood; or of an heir patiently abiding the death of his kinsman.

This state of things surely cannot be protracted. Nor would it, if a vitiated public opinion did not depreciate other avocations, and make the professions the only stepping-stones to character, promotion and influence.

Why has the ancient and honorable occupation of agriculture been brought down from the high position assigned it in the allotments of Providence and the true interests of nations, to rank with those employments that lie level with the grossest natures and the darkest minds? Why is it that the cultivators of the earth are never recognised, in their true character, as the best citizens in times of peace, and the bravest defenders in the day of war, except when their numbers are reckoned for political purposes? The policy of bringing the moneyed interest in opposition to the landed, or of crowding out the sovereigns of the soil, by the concentration of all political influence in the hands of the professional, is mischievous to the last degree upon the character of the people and the stability of legislation. Whether by statute or by conventional arrangement it is immaterial, the effect is to create a sort of informal corporation—a class of men who merge the love of country in the love of gold and of self, and who would sustain liberty or promote disorganization, as the calculations of personal interest might show that either would enure to their aggrandizement. The distinctions and offices of the State, under this system, become, to a large extent, the hereditary property of professed politicians and political adventurers, who, having no interest in the country, daringly sport with its vital concerns, and mock the people with fair words, while they abuse their franchises. With no rule of action but the retention of popularity, and no scruples about the character of the means, when they promise success, the world of politics becomes one vast laboratory, and the credulity of the people the crucible in which these political alchemists work out their endless experiments. On the principle that thunder purifies the atmosphere and tempests leave salubrity behind them, these little human Jupiters are for ever thundering. Panic after panic comes on—the cloven foot of oppression peeps from every enactment for which these men, or their party, cannot claim paternity; and, like the witch in the fable, who raised an earthquake to find her lap-dog, they are for ever shaking the heaven and earth of politics to get a name or keep an office. No marvel that the young and ambitious, seduced by this strategy, enter the list of competition, ready for every expedient of demagogueism, and perpetually strengthen the party we condemn.

The agricultural interest is the only one that, in all conjunctions, is identical with the peace, wealth, and true glory of the State and Nation. The investment of capital, labor, time, in the cultivation of the soil, makes patriotism synonymous with interest; and the happy moral influence it exerts upon those engaged in it, rears up a class who combine the domestic charities with the sterner civic virtues of frugality and valor, industry and independence. And whenever there is force enough in public opinion, or wisdom enough in State policy, or influential example, to give pre-eminence to this employment—to multiply the possessors of the soil—to elevate them in knowledge and social character and political importance, Georgia will have developed a secret of wealth and power more fruitful than her mines, and less fickle than the price of her great staple. As the Englishman, wherever he wanders, wherever he toils, turns his eyes and his hopes to Albion's white cliffs, nor rests till, his fortune made, he returns to the parent land to enrich it with his treasures—so here local affections would spring into bloom and fragrance and fruitfulness. Population would multiply—stability its law; improvement its pride. Science would enrich the soil, and taste embellish the habitations of the people. Our barren hills would smile with plenty, and our country seats would be the retreats of virtue and the home of the graces. The spirit of rivalry, without its bitterness, would pass over the land to vivify the dormant energies of the citizens, and the face of the earth would blossom as if a primeval spring were about to usher in another Eden. The social hearth, the festive board, the field, the wayside, would be the theatres where genius would dispense its treasures and intelligence diffuse its light—general education would rise in value and grow catholic in its blessings—literature would return from her exile radiant with glory, and life itself put on charms for ever new.

The history of education throughout the civilized world will sustain the observation, that the most efficient mode of promoting common-school instruction, is to foster, by a liberal provision, the higher institutions of learning. There must be a parent tree, shooting its vigorous roots far and wide, and casting its seed upon the pilgrim winds, if you would stock the land with kindred scions. Common-schools constitute one of the varieties of educational appliances, demanded by the diversified condition of a numerous population; but the sphere in which they operate, can never reach the motives and energies that must be stirred to produce a college. Any effort to supply the last with pupils, and means, by an exclusive enactment, in behalf of the former, is an effort to invert the laws of society, and the natural relation of things, as futile and absurd as would be an attempt to irradiate the heavens by a congregation of glow-worms when the sun was in an eclipse. Light descends; it is nature's law. If you would bespangle the sky with stars, lead forth the moon in brightness and bathe the earth in splendor, kindle the sun. The people, the churches of Georgia, tantalized for years by the legal guardians of this great interest, have taken into their own hands the work of popular instruction. Under their auspices, by voluntary contributions, colleges have sprung into existence; and within their walls, hundreds will be trained to knowledge and usefulness, who else would have groped in the gloom of obscurity, to fortune and to fame unknown. These institutions did not originate in the spirit of illiberal rivalship, or from the impulse of enmity to this ancient and honorable "mother of us all."*

*Franklin College.

She, venerable for her age and honored for her instructions, dwells in the affections of her sons unrivalled and alone. The Priestess of learning, the minster of knowledge, let the people rise up and do her reverence. *They*, allies and auxilaries in the same general cause, aspire to fellowship in usefulness and community in honor. Franklin, Mercer, Oglethorpe, and Emory, a brilliant constellation—Georgia's diadem, more precious far than the jewelled crown

"That rounds the mortal temples of a king."

Nor must I forget "that bright particular star" that beams from Macon's hill—a literary Venus, whose morning and evening light, sheds the hope of brilliant prophecy on the future destiny of Georgia's beauteous daughters.

The annual contributions of the first named colleges, to the intelligence and public character of the State, entitle them to the confidence and the patronage of the citizens. The advantages are numerous and diversified. The mere accession to the numbers of our educated men, is no insignificant consideration; but when we remember that the large majority of the graduates are dependent upon their personal exertions for support, and the fact that the professions of law and medicine cannot sustain them all, a necessity arises full of promise to the future advancement of the State. Education is neither bread nor raiment—employment must be had. The desire of independence—the pressure of want—the condition of character, all enforce the obligation of industry. In the distribution of the talents and knowledge of the State, every department will come in for a share; discrimination will resume its office, and the professions which have grown cumbrous and unprofitable, by an ill-judged monopoly, will be left to the wise and healthful operation of incidental protection. The school-house—the theatre of useful employment, honorable toil and ample remuneration—so long repudiated by Southern scholars, will be filled from among ourselves, and our disreputable dependence come to an end. I mean no insinuation against the men who have served us; they are honorable men and deserve the gratitude of the country. But it is a maxim of political economy, that no State can be be permanently prosperous and happy, unless she cherish and develope the elements of internal independence. A system of agriculture, which imposes the tax of buying all we consume, not less surely impoverishes the land and the people, than will the importation of teachers circumscribe the benefits of education and obscure the honor of this noble occupation. Let our graduates enter our village academies, locate themselves in country neighborhoods, and bring the advantages of knowledge home to the eyes and the hearts of the people. They will perceive them to be an ornament of character, a source of profit, a qualification for usefulness; and estimating their value by these utilitarian standards, will feel and appreciate their worth. The spirit of emulation will be kindled, patrons of learning multiply, our college classes swell to their appropriate size, and these intellectual fire-balls that have been accustomed to perform their splendid tours along the political heavens far beyond the range of popular vision will stoop to enlighten the land that gave them birth.

Science will lift agriculture from the level of mere drudgery to the elevation that belongs to it; taste remodel the uncomely arrangements that now blur and blot the face of the earth, and trees, and arbors, and gardens beautify the habitations of our people; and amid rural scenes and the innocent occupations of country life, many a now idle hand will have work to do, and many a weary heart find a home, its passions at rest and its virtues in bloom.

These denominational institutions are not the nurseries of prejudice and bigotry, exclusive sectarian inclosures where churches plan for power and the priesthood scheme for dominion, but the offspring of a patriotic religion; they seek to expand thought in the light of the Bible, and baptize character in the spirit of christianity. They were never intended to supersede the State University in the affections of the people, to abridge its usefulness or to reflect upon its character. Nor have they operated to its injury. Different vessels under the same flag, they constitute but one navy, a home squadron, the credentials of Georgia's spirit and the bulwark of Georgia's strength. Every mind reclaimed from ignorance, every error corrected, every moral enemy forestalled, is wealth and peace and glory won for Georgia.

If the history of this institution did not warn me that to hope was to be mocked, I would express the wish that the State might, by liberal donations, contribute to endow them all. To discriminate would be invidious and unjust. And certain I am, no man, no church desires it. But as instruments of general usefulness, they deserve to be cherished. Patriotism demands it and sound policy would approve the deed. But alas! for the country, it might not be popular with the people, and the time-serving politicians of these degenerate days love them too well to offend their prejudices. Hope dies within me when I remember that the appropriation for Franklin College has been the subject of an annual contest in the halls of legislation, and that the champions of ignorance, the knights of economy, have at last despoiled her. Ignoble achievement!—a stigma upon the legislation---a blot upon the history of the State. Our Alma Mater has been slandered to justify her spoliation, and the ruthless enemies of light and truth who have been the instruments of her injury, insult the understanding of the people in the expectation of their approval. And if the mass are ignorant of their true interests, duped by prejudice and delusion, that man is neither philanthropist or patriot or statesman, who becomes the organ of their senseless mouthings and the executor of their vandal will. Let oblivion be his tomb; nor monument nor epitaph transmit his name to another generation. Georgia needs men, high minded men, who will dare to brave the misapprehension and censure of the multitude; who will move in advance of popular opinion, and stand by right, unappalled by the opposition of party, undaunted by the desertion of the time-serving; men who, fearless of misconstruction, shall abide in indomitable virtue, strong, the watchlights of the land, to whose steady lustre desponding patriotism may turn with hope her languid eye, and from whose inspiring beam she may relume the glow of a quenchless courage. Would that I could heave from the depth of society a giant wave of indignation, whose onward roll should bear down prejudice and error, and toss upon its scornful crest the parasites that hang about the skirts of power, and beat with resistless fury upon the last stronghold of darkness and crime.

I long to see the day, when devotion to party shall be lost in the love of country, and our colleges, enshrined in the confidence and affection of a generous population, shall be the instruments of a refined and harmonizing culture to all the people. I long to see the day, when a taste for the beautiful in nature and art shall moderate the passion for vulgar excitement and sensual indulgence, when the employments that embellish life and relieve its monotony shall kindle in every bosom the love of home, and blend the intercourse of old and young in one beautiful picture of duty and delight. I long to see the day, when our gallant State shall walk abroad in the freedom of all her faculties, travelling into the regions of philosophy and literature to gather the wealth of ages gone, when her colleges shall rank with the proudest in the land, and the poorest citizen shall know how to read and to write, and when the star that now sheds a dubious light on Georgia's fortunes shall swell into a broad and blazing sun, and stream in glory unexhausted and inexhaustible.

On you, gentlemen, and your co-partners in privilege and position, devolves the duty of promoting this high civilization. Whatever the gifts of nature, Providence, or grace—employ, appropriate them all. Cultivate a public spirit. If, seduced by the blandishments of pleasure, you have lived in inglorious idleness; or, dispirited by the listlessness of the people, have resigned the hope of change—repent, reform, rouse, rally; and the achievement of the future shall redeem the shame of the past. Enterprise can triumph over difficulty; virtue will reap its reward. Education may, must vindicate its claims to patronage and diffusion by the refinement, the character, the usefulness of its recipients and represen tatives. Let your light shine; aspire to be the benefactors of your country. Born and bred upon her soil, defended by her laws, enlightened by her institutions, let Georgia reap the reward of her bounty in the consecration of your talents to her service. Promote knowledge, foster improvement, advocate sound morals by precept and example. The lofty gratification of doing good will cheer your labors and the honors of a generous population crown your days. The future history of the State will be the fulfilment of our proudest expectations, and peace and plenty bless this land of our hearts, our hopes and our homes.

BOTANY.

On the obligation of every Young Farmer to become acquainted with the history and character of the plants that come every day under his observation.

Extract from an Address de ivered before the Agricultural Society of Newcastle, Delaware, September, 1843. By JOHN S. SKINNER, Esq.

While I would thus urge upon agriculturists, and especially upon the young class, the importance of a correcter knowledge of *all* that belongs to the profession, I shall limit what I have to say to a few cursory remarks on the propriety of being accurately acquainted with the history and character of those *Plants*, whether valuable or pernicious, which come under the daily notice of the farmer. Without derogating in the slightest degree from the importance of the other departments of Natural History, it may be safely affirmed that the *vegetable creation* presents an eminent claim to the consideration of the cultivators of the soil. It is emphatically with the *products of vegetation*—the great source of animal subsistence—that the agriculturist is concerned; and if in other pursuits the operative finds it necessary to be well acquainted with his materials, it cannot be less desirable that the farmer should have an accurate knowledge of those objects which demand his care and attention. With such knowledge, he can not only understand precisely what plants are most worthy of culture, but, what is scarcely less important, he can comprehend the true character of those which require all his vigilance to exclude or to extirpate from his grounds. He can not only identify, to his own satisfaction, the plants which it behooves him to know, but, by the use of an appropriate nomenclature, he can make himself perfectly intelligible when communicating his information to others. The want of this knowledge, and especially the uncertainty of popular names, is a source of much confusion and perplexity in the intercourse of farmers, and in the essays of agricultural writers.* Every district of country, and almost every neighborhood, has its own names for well-known plants; but they are apt to be variously applied, the same plant being frequently known by different names, and the same name often bestowed on very distinct plants. A striking instance of this may be cited, by way of illustration, in the use of the term *Herd's grass*, which, in *New England*, is applied to the grass known to us by the name of *Timothy*, or the *Phleum pratense* of the botanists; whereas, in *Pennsylvania*, and perhaps in all the States

*We almost every day see high wrought notices of plants, supposed by the writers to be new or unknown, and which set the curious all agog to learn what the wonderful novelties may be, when nine times out of ten, if the proper scientific names were given, we should recognise them as old acquaintances, and should always be able to form a tolerable estimate of their value, by a knowledge of their botanical character and affinities. In all such cases, there is no surer protection against imposition, or what is vulgarly called *humbug*, than a competent acquaintance with the first principles of Natural History, which should be taught, and considered as an indispensable branch of education, in every school throughout the land.

south of it, the term *Herd's grass* is appropriated to a plant technically called *Agrostis vulgaris*, entirely distinct from the preceding and of inferior value. This discrepancy is liable to cause annoying mistakes, and has even been the occasion of litigation between the seedsmen of Boston and Philadelphia. I can perceive no remedy for the errors and confusion resulting from a loose and variable popular nomenclature but a resort to the precise scientific names imposed by systematic writers. The use of popular names may answer every purpose in colloquial intercourse with our neighbors; but when we wish to be explicitly understood by strangers, or by persons in trade, it would be better to employ the exact language of science, and to use those *names* for objects which have a specific meaning, recognised by all the world. Nor need this be regarded as an onerous task, so far as the practical farmer is concerned. To attempt to master the nomenclature of the whole vegetable kingdom would indeed be a hopeless and futile undertaking, but to be able to designate by the appropriate names all those plants which he finds deserving on his grounds is an accomplishment which every *young* farmer, at least, should resolve to acquire. In the middle States there are to be met with on our farms perhaps *one hundred species* of plants which claim attention, either for their valuable or pernicious qualities, or which ought to be expelled as worthless occupants to the soil. These ought to be well known to every farmer; and surely no intelligent man can doubt his ability to learn the names and characters of that number, when he recollects the facility with which all the world acquired the scientific name of a plant of recent notoriety. The classical name of *Morus Multicaulis* has become as familiar as a household word in the mouths of the most illiterate rustics in the land; and it would be a libel on the intellect of American farmers to insinuate that they could not become equally well acquainted with those other plants which are daily before their eyes, either claiming their care or requiring extirpation.

In truth, the well-bred agriculturist, whose business it eminently is to study and turn to good account the products of the soil, ought to know the name, the character, and the entire history of *every plant* that he meets with on his premises, or approaches him from those of his neighbors: but all I ask as a commencement is, that he should learn to know the limited number which it is his immediate interest to know, and of which it is disreputable as well as disadvantageous to be ignorant. Many worthy persons, I am aware, allege as an excuse for their deficiency in this kind of knowledge that they *have not time* to acquire it; but I beg leave to intimate to such, that they have mistaken the nature of their complaint. It is not so much the *want of time* which afflicts them, as the *want of taste* and the *neglect of opportunities*. We all idle away countless hours of our existence, and especially in the morning of life, which might be successfully devoted to the attainment of useful knowledge. *Taste* is a faculty which can be cultivated; and *opportunities* to be improved happen to all men. It is impossible for an intelligent observer to ramble amid the works of creation without acquiring some knowledge of their character; and if he cultivates the habit, he will insensibly accumulate an amount of information, which, to the careless, seems to be the result of long and laborious research. Some of the most successful students of nature I have ever known prosecuted their inquiries under a constant pressure of the every-day cares and duties of life, and yet were remarkable for the exemplary performance of those duties. It will not avail, therefore, in this age and nation, to plead a *want of time* as an excuse for neglecting those attainments which are due alike to the best interests and to the high character of our profession. But if the practical farmer shall still insist that it is incompatible with his turn of mind and habitual employments to indulge in this kind of research, there is a simple and ready method by which he may obtain a sufficient knowledge of all the plants which present themselves to his notice, and seem to require his attention. Let him collect a fair specimen of every such plant, both in flower and fruit; let the specimen be carefully pressed and dried so as to exhibit the characters; and let each species be preserved in a distinct sheet of papaper, accompanied with a label, designating *the place of growth*, *the date of collection*, and *the common name or names* by which it may be known, together with any remarks that may tend to illustrate its history or properties. The specimens, thus prepared, will then require nothing more than the *scientific names* to determine their identity when spoken of, and to render them intelligible to all the world. Those names can be readily obtained from botanical friends, who always take pleasure in affording such information; and thus, with a very trifling labor, (I should rather call it an instructive amusement,) and in the compass of a convenient volume, the farmer may have always at hand the means of knowing by name, by sight and by character all the plants of his vicinage in which he has the slightest interest. When memory fails, or doubts arise concerning the identity of any particular species, he can turn to the standard specimens in his little *Herbarium*, as the scholar does to his dictionary, in the full confidence of obtaining a solution of his difficulties. His knowledge will be of that authentic kind which results from ocular demonstration; and by employing terms which convey definite ideas, he can communicate what he knows with clearness and precision.

Upon this simple and feasible plan may be obtained a fund of accurate information, which would serve as a basis, or starting point, for more extended and important attainments. The intercourse between agriculturists would become more interesting and profitable, because they would better understand each other. In discussing the merits or demerits of any given plant, they would know exactly what they were talking about; and not waste their arguments, as they sometimes do, under an utter misconception of the object in dispute. A *Kentuckian* and a *Pennsylvanian*, for example, are liable to exchange opinions concerning the value of "*Blue Grass*," in their pastures, without being aware that they have reference to entirely distinct species. Similar mistakes often occur in relation to noxious weeds. I have seen an excellent farmer waging war with the common *wild chamomile*, (*Anthemis Cotula, L.*) in the belief that he was contending with the *Ox-eye Daisy*, (*Chrysanthemum Lucanthemum, L*) a vile nuisance, which has been permitted, partly by ignorance, but more by a culpable negligence, to overrun a large portion of our country: and in one of our gazettes, a few years since, a series of vigorous essays appeared, calling the attention of farmers to the *wild Teasel*, (*Dipsacus sylvestris, L.*) a comparatively harmless biennial, and denouncing it under the full persuasion of its being that formidable pest, the *Canada Thistle*, (*Circuim arvense*, Scop:) while the real Canada Thistle was extending itself, in the immediate vicinity of the essayist, unnoticed and unknown!

Such errors are not only prejudicial to the farming interest, but absolutely disreputable to the profession: and I have so much of the *esprit de corps* about me, that I am ambitious to see a correct knowledge of those objects which immediately concern me diffused throughout the whole agricultural community. I certainly believe it to be entirely practicable, in the mode I have indicated, otherwise I should not have ventured to trespass upon your time and patience in urging its attainment.

I have insisted upon the necessity of studying the character of *weeds*, as well as of useful plants, because it will be found that the pernicious and worthless species amount to more than *three-fourths* of all those which occur on our farms, in this latitude: and, I may add, that *nine-tenths* of the most pestilent intruders have been introduced from abroad. Hence it is indispensable to neat farming to possess a knowledge of all that ought to be excluded from our premises, as well as of those deserving culture. We should not only have this knowledge, but it must be accompanied by unceasing vigilance. The utmost care should be observed in the selection of seeds; and whenever a plant of strange or suspicious character makes its appearance it should be promptly attended to. Many weeds are disseminated in a single season, so as to cause much labor and trouble in getting rid of them; and a few years of slovenly neglect will often render their thorough extirpation an almost hopeless task. There should be a cordial co-operation among the whole fraternity in resisting noxious invaders; for the carelessness of one individual may be a source of grievous annoyance to a whole neighborhood. The sloven should be shamed out of his negligence, and the ignorant induced to seek knowledge by the successful *example* of his brethren; for example will ever be found contagious—as well for good as for evil.

From the American Agriculturist.

MERINO SHEEP.

Having of late taken much interest in the growth of wool, and incidently in the best breed of sheep for that purpose, I have concluded from all that I can learn of the present flock-masters of the country, the prices of wool, and the condition of our American lands for the wool-growing, that the original Spanish sheep, of the importation from 1802 to 1815, are the best for the general farmer, and particularly for my own purposes. Many years since, I was interested in the sheep of some of those importations, and I well recollect their fine, substantial forms; their well-covered bodies; and the beautiful and uniform fleeces which they annually yielded. But, so far as I can understand, those animals have many years ago passed away in the drooping interest that our people have suffered in the production of the valuable wools; and more than that, in the impatient, fidgety, and uneasy propensity of the American character to change and cross everything of the animal kind which they possess, and the proverbial disposition we have of not "letting well enough alone."

The upshot of all this is, that the ancient flocks of our Merinos, (by ancient, I mean from 25 to 40 years ago,) have been Saxonized by the numerous flocks imported in the years 1825, '6, and '7, principally in speculation. Indeed, these animals, vastly inferior, in my estimation, for the interest of the American wool-grower, to the Spanish sheep, were greedily, and without due deliberation, seized upon by the breeders to improve them. The result has been, an absolute deterioration of their flocks, in constitution, size and weight of fleece, and as I too much fear, the *almost* extinction of the true descendants of the old Spanish sheep from our country. At all events, I have examined several flocks the past season, and among them all I seldom recognised anything that came up to the splendid old originals of the early Spanish sheep imported by Livingston and Humphrey in the early days, and afterward in many select flocks, by several other distinguished sheep fanciers and breeders of that day. There was a character of nobility in their look; a cavalier measure in their tread; and the dignity of an old Spanish don in their presence, which outmeasured anything now seen, except occasionally, among the so-styled Merino flocks of the country. This deterioration is admitted by all with whom I conversed, to be caused by the promiscuous breeding in of the Saxons with the Merinos. In corroboration of this sentiment, I have also the opinions of some of the largest wool merchants of the northern and eastern cities, who unequivocally declare, that the qualities of our wool have gradually been changing from the fine, close, yellow fleece of the Spanish Merino, into the texture of the less hardy, yet finer and whiter, Saxon.

I have for some months been much interested in a sort of controversy which has been carried on in your paper regarding the merits of some sheep, described as being bred in Vermont, and

said by their breeders to be pure Paular Merinos. These animals also have much notoriety in the columns of some of our agricultural papers, where they have been figured, not at all to their credit, nor as proof, (if the pictures be correct likeness,) in my opinion, of the purity of their blood; as either Paulars, or as specimens or the Spanish Merino at all. How this may be, however, I will not pretend to say. *Per contra* to this are the caustic, and, as I think, unnecessarily severe strictures of Examiner in the Agriculturalist. So far as the *facts* of the Examiner are concerned, my own evidence of the present condition of fine-woolled sheep in America corroborate them; but his personalities can have little bearing on the *real* argument as to the existence of, or purity of blood of our fine-woolled sheep generally.

In regard to the existence of the *Paular* as a distinctive variety of the Spanish sheep, in the United States, I infer that they are a *fancy* breed now existing only in the imagination of their proprietors; for so far as I have been able to ascertain, but very few of that valuable variety ever were imported into America at all; and the inveterate propensity of the "universal Yankee nation" to intermix everything of the animal kind, could hardly have left these to escape the usual fate of all things else. I also believe this from the statements of very many highly creditable individuals in different parts of the Union, who have much experience in sheep-breeding, and an intimate knowledge of the principal flocks throughout the country.

Mr. Jarvis, of Vermont, who probably imported more Spanish sheep than any other single individual in the United States, declares in his essay last winter, published in the Boston Cultivator, that his own flock, although kept separate in their varieties for a long time, were all mixed some years ago, and since then he has bred them indiscriminately. It is also asserted by those who have abundant opportunity to know from personal observation, and by wool dealers, who have purchased his wool, that the Saxon blood has prevailed to a great extent among his flock of late years. So also of most, indeed, perhaps, every other *large* flock in the United States. Now and then, select small flocks may possibly be found, few and far between, the relics of some well-cared-for, and choice animals which have not been intermixed with Saxon or other blood. Yet it may in truth be said, if we believe the disinterested testimony of the great body of wool growers throughout the United States, no candid mind can rely upon obtaining pure unalloyed Spanish sheep in any considerable numbers. It appears to me, that the persons who have recommended their animals to the public attention through the agricultural press as pure Merinos, and the blood of which has been impeached should, in justice to themselves, substantiate the pedigrees by unimpeachable evidence. In pursuing this course, imposition may be avoided, and the public confidence restored in such individuals as now stand by public accusation in the unenviable position of selling spurious animals under false names; and as both myself and many of my friends require thoroughbred Spanish rams for the restoration of our flocks, it is not to be doubted that such animals, if existing in the United States will meet with ready encouragement from systematic wool-growers.

As to the Rambouillet sheep of Mr. Collins, I have seen only one or two specimens of his flock. The staple of their wool is remarkably nice, and shows all the fine, silky, softness and length of the most approved Merino of "the olden time." Yet as these are so few in number, I understand that no more of his sheep are for sale at present, my own and the applications of others being refused at any price, they do not appear likely to supply the public demand, at all events, for some time to come.

L. F. Allen.

Black Rock, October, 1844.

☞ The navigation of the Hudson was open at Albany on Monday.

FRUIT AT THE SOUTH.

I presume the idea must have originated here, that our country was unsuited to fruits; but that idea does even now exist to a greater or less extent, and consequently those who do attempt it make failure almost sure, and thus prove the hypothesis—at least to their satisfaction. But thanks to the inquiring age, the indomitable energy of some, and the light of agricultural periodicals, this matter is undergoing a vast change; and I hope, ere many years pass, that our whole country will be convinced that we have a fruit country, and that all of my countrymen will avail themselves of this great blessing. I look on fruits as peculiarly suited to our wants, and thinking as I do, I should be forced into the inference that our Creator had fallen short in his perfect work, if our climate was unsuited to the easy production of fruit.

In warm climates, fruit is conducive to health (ripe fruit, of course,) and if we could have it of a good quality, and in abundance. I think the scourge of our land, *fever*, would be more under our control. In the first place, we all know that the bile formed in our system is secreted in greater abundance in summer than winter, and I think if we would use less food that has carbon as its principal constituent, that we should be exempt from at least much of this increased flow of bile. Fruit is an article of this description; and requiring less carbon to keep our system in operation in the summer, with a great desire for this article, fruit, I think that we could with marked benefit use it freely, and to a greater extent than our northern brethren. I do not desire to enter into the subject more fully; it has been trenched on by many, and only add, that it seems to me, the oxygen in the fruit will combine with carbon in the system, and pass off harmless. You will therefore conclude I regard fruit as conducive to health, which I do.

I put it, on another footing, as our pecuniary interest. All manner of stock will feed on fruit, and most of them will improve in condition; besides, it will act on them as on man as to health —prevent disease. What number of hogs an orchard of 20 acres of good peaches and plums would keep in excellent condition from 1st of May to 1st of September or October, I can not form an idea; but I know this much, that hogs in an orchard of the Chickasaw plum (common plum of all this region) will not come to call, and presume that they would readily come for corn if this fruit was not to their taste. I think that acre for acre, the same land will feed as well as it in corn; for if the orchard be cultivated as I deem it should be, plowed once every spring, and left until the fruit ripens, it will produce quite a pasture of crab-grass, which of itself will fatten stock. And yet another advantage, which is now no longer hypothetical; fruit is profitable to ship to New Orleans, and those who live within even 20 to 30 miles of the Mississippi river can make it profitable, though of course not so much so as if living nearer. I do not see any reason why we might not sell in New Orleans alone 200 to 500 barrels per day of choice peaches, beside a large quantity to the planters on the Mississippi, where steepage water prevents their growing peach and standard trees, to say nothing of Upper Mississippi and its tributaries. Understand, we can ship excellent fruit by the middle of June, and some of the early varieties two weeks earlier—this is of peaches; our strawberries can be sent up and down early enough to pay us well, beside which, the travelling custom on the Mississippi river is immense. We have therefore three good reasons, if I am correct in the first; beside which I state the gratification of our own taste and that of our visitors, as well as the moral bearing. Who would think of offering his friend a glass, when he could place before him, from the 15th of May to the 1st of October, the strawberry, melon, and peach, in season, and apples and pears, &c., all winter?

The peaches will grow here to perfection, equal to any point in these United States; who will affirm to the contrary? If any be found so hardy, and will come here, I pledge my head to prove to him he errs, and will go no farther than Hatch's or Lambert's, or my friend Hebron in Warren county. I have bought peaches in the Philadelphia market at 12½ cents each, and excellent they were. I was in that most delightful city for two years, and saw choice fruits of all kinds, and I do aver, I never saw there a finer peach than I can show on this place in August. There has been shipped in one day, at Vicksburg, for New Orleans, on one boat, 200 barrels of peaches; this proves something.

Many persons rely on seedlings, and will not be convinced by the sad experience of some of us. Mr. Hebron has planted out not less than 1,000 seedlings, and I presume in the last twelve years I have done the same. What are they worth, with all our trouble? Both of us have budded to the sprouts, or tender limbs of over 90 per cent. of our seedlings, I guess, intending to cut down the trees of three to five years old; this shows *our* estimate.

Too many plant fruit trees on worthless land, for noting else. This might do if they would remove four to six feet square of the clay, full three feet deep, and fill up the hole with earth from virgin soil or the woodpile, and then run a subsoil plow eighteen inches deep. I have never elsewhere seen nectarines succeed as well as in this country; I think they do equally as well as the peach. The raspberry of several kinds is very excellent. Summer and fall apples and pears do full as well, so far as our limited experience proves anything. The only difficulty is, your winter fruits transplanted here, ripen too soon for us; but I think time and experience will remedy this in our rearing winter fruits to suit our latitude. The quince I never saw finer; several varieties of the plum do well, and do not fail in one year out of fifteen. The fine plums, cherries, and apricots, have not been tested sufficiently to say anything for or against them. Of the latter I know some few gentlemen who say there is no difficulty at all. The grape will unquestionably succeed admirably. Think of sticking a cutting twelve inches long into the ground, and no more preparation; and yet many cut grapes from such culture.—The fig—go south of us for the best, but not north of us for better.

The cultivation of fruits has as yet in reality received no such attention as you northern folks describe. We dig a hole some fifteen or eighteen inches square, about a foot deep, make the roots adapt themselves to this size, plant sometimes deep and sometimes shallow, owing to ease of digging the hole, and let it grow or not! This is truly about the amount of labor in planting our fruit trees. There are exceptions, I know, but this is the plan. We then plant corn, or cotton, or grain, as it happens to suit, and grow our fruits. Is it any wonder that we have not the rich, luscious fruit of the north?

But we had better stop here, for I have said enough at this time, which I trust most earnestly, will induce some reader of yours to try the cultivation of choice fruits in a correct manner, and I do this with the firm belief that he will succeed, and if influenced to do so by this article, that he will feel thankful to the columns of the American Agriculturist for this advice.

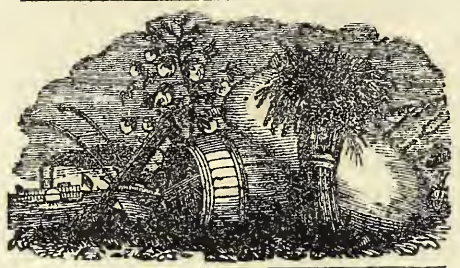
M. W. Philips.

Edwards' Depot, Miss., Oct, 1, 1844.

N. B. We had frost here on the mornings of the 29th and 30th September. I have never known it so early before. Judge Noland, who has been here some thirty years, says it is the first frost in September he ever saw. The frost was plain, when the sun was an hour high.

NIGHT SOIL.

Our farmers might add materially to their supply of manure, by constructing their privies so as to enable them to make use of their contents. A gentleman from Connecticut informs us that he mixed his soil with muck, adding a small quantity of lime and ashes, and made manure enough for five acres, which he planted to corn, and that the crop is equal, if not superior, to any one he has seen.



WEDNESDAY, DECEMBER 25, 1844.

To our Patrons.—The period, the close of a volume, seems to suggest that we should say a few words to those upon whose kind indulgence we have relied, for the many short-comings in the discharge of our duties. Well, what shall we say? We need not apologise now, for the evil would not, cannot be corrected by an apology. We have known and felt that our other duties demanded too much of our time and attention to do justice to the Cultivator; and to make ample reparation for our own remisness, we have yielded the chair Editorial to another and much more gifted occupant—and we hope by his aid to present to the Southern Planters a work that would do honor to any section of the Union. To accomplish, however, a work so desirable in the present state of our husbandry, much depends, for the entire success of the enterprise, upon the planters themselves. They must not only subscribe for and read it themselves, but they must see that their neighbors and friends, in every department of business, are also patrons of the "Southern Cultivator. By this means, it will soon accomplish the greatest possible good of which it is capable—for, not unlike the dews of heaven, it will diffuse its blessings wherever it may fall. The Publishers and Editor will endeavor faithfully to discharge their duties, and while waiting to see how the planters will come up to the rescue, we tender to each the compliments of the season.

☞ Those who intend subscribing for the third volume, should do so immediately—if possible, before the first of January. Hand your DOLLAR to the Post Master, and he will forward free of charge.

Who will get the Premiums?—If we may judge from present appearances, we should guess that our list of premiums will excite quite a rivalry among our friends—for we have already been advised that several gentlemen have entered the list for the most valuable goblet. This is as it should be, and if the prominent planters in the several counties would make an effort to secure a premium, our circulation would be commensurate with the future merits of the work, and its stability placed beyond the reach of contingency. What say you, gentlemen, *who will get the premiums?*

Renew your Subscriptions.—As this is the period when all our subscriptions terminate, we beg leave to remark, to those of our readers who wish to continue the paper, that they must forward the money in advance. The low price at which the work is published, forbids the idea of extending any credit, even if we had any inclination. Our terms are strictly enforced, and no man gets a paper unless he pays in advance. We speak plainly, because everything demands that we should be plain.

Bommer's Patent.—By a letter from Mr. Charles Baer, now in Charleston, we are informed that he will soon visit Augusta, for the purpose of vending his Patent for making Manure. As Mr. Baer, in all cases where it is desired, tests the efficacy of the plan, those who wish his services in instructing and showing them the application of the Patent can obtain them by leaving a notice at this office.

[*From the Boston Evening Transcript.*]

View from the Pyramids of Egypt, Anecdotes, Facts, &c.

The following *recollections* of Mr. Gliddon's 4th lecture, we doubt not, will interest such of our readers as prefer to let the memory dwell upon the single thoughts of a discourse, rather than upon the combined ideas of the *whole*, which is often confused and embarrassed. Indeed, if there be a fault in Mr. G.'s lectures, it is the complexity of his facts and their thick grouping together. They are sufficiently numerous in each lecture to form three of moderate length and *fashionable profundity.*

No description hitherto given by poets, printers, historians or philosophers, comes up to the merits of the view from the Pyramids, nor does any *printing* yet put forth attempt to approach the *fac simile.* Dr. Lepsius has caused a panoramic view to be taken from the summit of the second Pyramid, which, said Mr. Gliddon, will be valued by those who never expect to behold the reality; and the lecturer hoped that besides *the day* view, the Prussians would add their *night* scene of New Year's Eve, 1842, where the blaze of *bonfires* lighted on the top of each three pyramids cast a lurid glare on every side, bringing out the craggy peaks of the long desecrated Mausoleum of Memphite Pharaohs, tinting the dreary wilderness of tombs with a light, emblematical of Lepsius's vindication of their inmates, and leaving the fitful shadows of funeral gloom to symbolise the fifty centuries of historic night now broken by the Hierologists!

"No other scene on earth," said Mr. Gliddon, with a natural enthusiasm excited by the vivid remembrance of the reality which had been seen like a map before him—"no other scene on earth presents at one view and in one series, to the evidence of the senses, such monuments of *Man.* Beginning from an antiquity antecedent to all history, and unfolding their respective ages before the gaze, associated with the sublimest deeds of human greatness, or bedewed with the sad tears shed by unnumbered successions of varied nations, until step by step, generation after generation, century after century, Empire by Empire, his eye follows each monument, down from the mighty *Pyramid* that has survived 5000 suns, to the frail and ephemeral Arab hovel, which, with fresh Nile mud and a few canes, yonder Fallahs are raising for their habitation, and yet from the summit of the Great *Pyramid* you behold the *all!*"

Continuing the lecture, and giving many statistics of admeasurements, chambers, passages, &c., in the Great Pyramid of Cheops, as well as showing that the ancient *Cubit* guided the construction of all its parts, Mr. Gliddon related an anecdote with regard to two small lateral apertures that had been seen in the Pyramid, but the purpose or end of which remained inexplicable to all explorers until 1837, when Col. Vyse discovered that they were the inner mouths of Air Channels, extending on each side to the surface of the Pyramid. Whilst Col. Vyse's men were probing the northern Air Channel, they found it impossible to tell whether it was *open* all the way through, as palm sticks lashed together could not pass; stones, rolled in, stopped; and water, poured in, was absorbed by the masonry. An Arab solved the difficulty in a very simple method. He brought a cat with her young kittens in a sack, and placed the kittens at the bottom of the air hole in the King's Chamber, and shut them in with a stone; then going outside, he placed the cat at the opposite end, and shut her in also with a stone. On going inside again, after an interval, the cat, attracted by the cries of her offspring, being found with her little family at the bottom of the channel, *proved* that the passage was open from top to bottom! This anecdote, as Mr. Gliddon remarked, is not mentioned in Col. Vyse's great work, because they have recorded there, only the *scientific* methods of solving architectural problems!

It seems also that the outer mouth of the southern Air Channel was discovered accidentally by a man whose hat blew off his head whilst standing at the top of the pramid, and who discovered the hole which turned out to be this mouth as he went down the south side persuing his air taken beaver? The lecturer observed that the discovery of these air-holes was a most decided blessing to all explorers and tourists, relieving them essentially from an uncomfortable feeling of suffocation, at times both oppressive and deleterious. Issuing from these hoary places of sepulture, said Mr. G., and coming again to the ligat of day, your are lost in amazement at the *thousands* of tons of *granite*, alone, cut 640 miles off at the quarries of the first cataract, and rafted down the river by the Nile and by Canals to the foot of the Causeways, and thence dragged on sledges up inclined planes, to the Monument wherein they were fitted, after elevation by sheers, derricks, blocks and falls, by the application of Bullock power, and the sinewy arms of thousands upon thousands of aborers.

There was one part of this lecture which was peculiarly beautiful and striking; where, in allusion to the modern discoveries in connection with Egypt, and especially to the fortunate explorations by the Prussian Expedition under Lepsius, Mr. Gliddon, as if with one quick glance at the past, the present, and the future, exclaimed with fervor,

"Dark has been thy night
——Oh Egypt! but the flame
Of new-born science gilds thine ancient name!"

And then quoting with a few slight alterations, the lines by W. O. Bourne, Esq., previously given in this paper, he instantly added, with skilful appropriateness:

"No more thy hieroglyphics shall tongueless be
The empty marvel of a wondering world;
For *Science* hath declared her bright decree,
And from the Tombs of Ages, mystery hurled!
Thy granite shall revive, and speak again,
Through the long lapse of years with freer tongue;
And *we* shall catch its words, nor seek in vain
The occult counsels in thy temples rung;
Champollion gave to mind the master-key;
He read thy records in the sacred sign;
Whilst drinking in at thy fount of Mysterie,
He learned the pategraphic to divine—
And Truth shall henceforth lend her brightening ray,
With *Lepsius'* aid to chase the lingering gloom away!"

The quotation was received with an applause which well indicated that the audience felt the force of his sentiment.

NEW SYSTEM OF MANURING.

A singular idea has just been suggested in Scotland in relation to the nutrition of plants. It may be summed up in a very few words, thus: that a sufficient quantity of the elements of nutrition may be absorbed in the seed of wheat, oats, and barley, &c., to ensure a very large product at harvest, without any other manure. Experiments have been made with complete success, and they have been published by the Agricultural Society of Scotland. Sulphate of Ammonia has been used, and nitrate of soda and potash, and all in combination.—*Albany Cultivator.*

☞ It is stated in the papers that a young wife in Lowell, Mass., has presented her husband with five children in eleven months!—An Editor asks—"Who can beat that?"

The Editor of the *Saturday Courier*, very feelingly answers—"*Who would wish to?*"

ORIGINAL COMMUNICATIONS.

For the Southern Cultivator.

REMARKS OF AN OLD CORRESPONDENT.

Mr. Editor:—I have long thought that it was the duty of each cultivator of the soil, to contribute something to the common stock of agricultural information; and if each member of the agricultural family would only do his part toward spreading useful information on the subject of husbandry, how greatly it would add to the happiness of mankind; for there is not an individual that follows the plow but could throw some light upon the subject of agriculture, were he disposed to do so. The great misfortune is, that nine-tenths of the cultivators of the soil, seem willing to turn over everything in the shape of writing, even on his own honorable business, to some member of the learned professions. Hence it is, that we find it so difficult to persuade the farmers, generally, to join an agricultural society, or to take an agricultural paper. For some years past, I have labored to keep up an agricultural society and to get the farmers to take agricultural papers. It is true, that I did succeed the year now coming to a close, in getting about thirty subscribers, having been myself a subscriber to those valuable works for twenty years, and at this time I take four works on farming, and I find them so profitable to me, that I contemplate continuing all four of them, notwithstanding the low price of cotton. All four only cost me four dollars, and they are, in my opinion, worth to me twenty. I would not be deprived of the pleasure of reading them for fifty dollars, to say nothing of the profit.

I sent you for publication, my plan of preparing my cotton for market; when it is sold, I will give you the price it brings. My fine cotton of last year, sold in December, in Apalachicola, for 10½ cents. It was sold in New York, in June, at 11 cents. Should an opportunity offer, I will send you a sample of my cotton.

I sent you, as you may remember, an analysis of blue marl, which you published some time past. I have hauled up something over a thousand bushels of it, and am preparing it as a compost this year. I first cover the lot where my cattle are penned every night with fine straw; I then spread over a coat of marl. After the cattle have remained on it for some time, I spread a second coat of straw. I have not yet determined whether I will manure my cotton by planting in the check or planting in the drill. I cultivate thin pine land. Should I be spared, I will give you the result of my experiment with the marl.

I was highly pleased to observe in your last number, that Mr. Camak, of Athens, is to be the Editor of the Southern Cultivator for the future. I know of no gentleman in the circle of my acquaintance, that I think so well calculated to take charge of an agricultural work. His mind has, for a number of years past, been turned to the subject of agriculture and horticulture. In addition to his being a fine writer, he is a practical man, and a man of industry and perseverance; and whatever he undertakes, he attends to it as it should be done. Indeed, Mr. Camak, I believe, will do for Southern Agriculture what the lamented Jesse Buel has done for Northern Husbandry, if the farmers will everywhere throughout the country come forward and patronise the Cultivator. And where is the cultivator of the soil, if it is only a garden, that will not give the pitiful sum of one dollar for about two hundred pages of matter, written by practical farmers, that relates to his every-day business, to say nothing of the hundred and one receipts of the most useful kind. When he reads the work, it will be equally valuable to hand down to his children. I will procure you all the subscribers in my power.

Yours, &c.

Eufala, Ala., 6th Dec., 1844.

For the Southern Cultivator.

BERKSHIRE HOGS.

Mr. Editor:—On a recent visit to the White Plains, I learned that Col. Bonner has sent to Alabama some of his most valuable, and finest Berkshire hogs, and in connection with Mr. Crook, of Benton county, will supply the good people of Alabama with the finest pigs of the *pure* Berkshire stock. Among the hogs sent, I notice the justly celebrated premium boar, Rip Van Winkle, well known in this county, and in New York too, for his large size, and fine proportions. Among the sows, were Nonesuch, (a premium sow,) Kitty Clover, Victoria, Adela, Nelly, and others, comprising a list of the choicest Berkshires to be found in the whole country, as they were carefully selected from the best stock, of the best breeders in New York.—But it is useless to particularize. I write this merely to direct the lovers of fine stock, and good pork, to where they may obtain the pure article. Just let them call on Mr. Jas. M. Crook, near Alexandria, Benton county, Ala., and they will find their highest expectations realized in "the stately Berkshires" he can exhibit.

H. C. W.

Woodville, Ga., Dec 4, 1844.

The Smithsonian Bequest.—*Model Farm.*—James Smithson, of London, bequeathed all his property to the United States, to found at Washington, under the name of the Smithsonian Institution, an establishment for the increase and diffusion of knowledge among men. The estate was sold soon after the death of the benevolent Englishman, and yielded the sum of $508,318, which was paid into the Treasury of the United States, December 3d, 1838. On the meeting of Congress next month, the interest due the Smithsonian Bequest by the Treasury of the United States will amount to one hundred and eighty-two thousand dollars. The whole fund will then amount to six hundred and ninety thousand dollars. We have added six per cent interest from the date the fund was paid into the Treasury. Six years have passed away since our agent received this money from the Executors in England, and yet nothing has been done by Congress to carry out the benevolent design of the testator.

At the close of the last session of Congress, Senator Tappan, of Ohio, introduced a bill for the establishment of the Smithsonian Institute, proposing the establishment of a Model Farm upon ten acres of ground in the vicinity of the Capitol, the agricultural and horticultural department to be conducted on the most approved plans, ample provision being made for experiments in farming and husbandry: the whole to be under the care of twelve citizens of ability and experience, appointed by Congress. Among the means of usefulness contemplated in the bill, is the distribution of such fruits, plants, seeds and vegetables, as shall be found useful and adapted to any of our soils and climates, so that the people in every part of the Union may enjoy the benefits and advantages of the experiments made by the institution. All instruction in the institution is to be gratuitous to those students who conform to the rules and regulations. Petitions in aid of this bill are now in circulation in various parts of the Union.—*New Bedford Mercury.*

The idea above suggested for investing a portion of the "Smithsonian fund," is certainly a very excellent one, and we sincerely hope it may, in some shape, be carried out.

But, common sense forbid that *twelve* persons should be appointed to manage a farm of ten acres!—that is, if fat salaries, as undoubtedly would be the case, are to be paid to the managers; and who, in the vicinity of *Washington*, would think of serving in the capacity of an agent of the government without *being well paid?* No, no! the atmosphere of the place smells so strong of "public plunder," that it is almost impossible to resist its influence! If the "Model Farm" is established, therefore, let it be somewhere else than in the District of Columbia; or, if that region is selected, Heaven forbid that a "round dozen" of salaried gentlemen should be called to preside over it!

Growth of American Cotton in India.—In regard to the culture of American cotton in Bengal, it must be admitted, that although the experiments have been numerous, and in some instances on an extended scale, the whole have hitherto been conducted by amateurs, many of whom having satisfied a temporary wish to try the culture, have abandoned it, whether successful or otherwise, so that it is almost impossible to form a decided opinion as to how far the cultivation would answer in a commercial point of view. Of late, however, there appears to be a desire on the part of the Government of Bengal to take up the culture, as evinced in the appointment last year of a gentleman who has had considerable experience in America, for the express purpose of reporting, after a careful investigation, on the capabilities of the soil and climate of Dacca, and the surrounding districts, for the introduction of the foreign staple. We alluded to this circumstance on a former occasion, and we now learn, from the reports which the Deputy-governor has considerately placed at the disposal of the Agricultural Society, and which were submitted at its last meeting, that during the last eight months Mr. Price has been engaged in travelling over various parts of Dacca, Furreedpore, Tippera, and Bulloah, situated on the Dultussary, Conni, Megna, Burrapootra, Luckia, and other rivers in that tract of country, and has seen many spots on which the foreign cotton could be cultivated to advantage, more particularly on the islands situated on the Hottea and Surdeep, as also on other small islands situated on the Hottea river, in consequence of their contiguity to the sea. —Some of his experiments have been successful, while others have failed; but in no instance does he appear to have received fresh seed in time to sow at the proper season; so, on this very essential point, he may be said to have labored under a great disadvantage, besides experiencing other minor difficulties incidental to nearly all first attempts at a new culture. Notwithstanding these natural obstacles, he seems to have seen enough to induce him to hold out sanguine hopes that, if advantage can be taken of the proper season, he will be able to cultivate the plant to advantage in the Dacca district. In consequence of this favorable opinion, we understand that Government have it in contemplation to commence the work in earnest, by the appropriation of such tracts in the district as, from previous examination, may be considered most fitting for the cultivation of American cotton, and to combine therewith a matter of even still greater importance, namely, the increased cultivation and improvement of the indigenous staple.—*Calcutta Star.*

IN FARMING—MANURE IS "THE PRINCIPAL THING."

To the Editor of the Marlboro' Gazette:

There are so many good *hints* in the enclosed extract from the last number of the New England Farmer, and there are so many of my acquaintances who ought to be ready to *take* them, that I cannot forbear asking you to give them a place in the Gazette.

The chief, the grand, I was going to say the sole object, with every farmer, should be the *accumulation of manure*, from one year's end to another, day in and day out, and from every possible resource. Not a single pound of feathers, or of hair—of horn or of hoof—not a single pint of ashes, or of soap suds, or of urine—not a weed, if it were possible to prevent it, should be lost—all—all should be saved and converted *into manure*. Of one thing, every farmer is certain, that *cultivation exhausts his land*—something, of course, must be done to *restore* that of which it is exhausted. How long will a horse work if he gets no feed? How long will the best cow give milk if she gets nothing to eat? Neither can a farm be worked and milked without being *fed*.

Instead of looking only to the stable, or the cow-pen, or barn-yard for manure, and managing them carelessly and unskilfully, the *thinking* farmer will reflect, that there is nothing which will *rot*, but what may be converted into good fattening food for his farm. If a horse dies on the farm, let him be covered with cart loads of earth, and the very gasses that escape in the course of putrefaction, will impregnate and make good manure of the whole mass. Let nothing be lost—not even the offal of poultry or the pigeon house. I. S. S.

"GLEANINGS ON THE FARM.—'*Gather up the fragments, that nothing be lost.*'—The first lesson in true economy is, to take care of small matters. When one has made a fixed principle of action, he will be very sure not to suffer more important matters to be neglected. There are many things scattered over the farm that are worth saving, and may be turned to profitable use, if taken care of *now*, but which will loose their value, if neglected much longer. Of this character, are substances for manure and litter—such as vines, potatoe tops, leaves, bog herbage, &c. The collection of leaves for manure is particularly deserving attention. 'For many years (says one who has practiced this,) I have been in the habit of collecting in the fall, leaves in my wood lot, and to use them as litter for my cattle through the winter. When the floor is cleared in the morning, the leaves and dung are turned over and chopped together, before they are thrown out. This kind of manure for potatoes, I find superior to any other I ever used; it unites the richness of animal matter with the sweetness of a woodland soil; and I feel confident that it not only contributes to the abundance of the crop, but that it ensures a superior quality. From the repeated benefits I have derived from the practice, my estimation of leaves has gradually increased, and they have become such an essential article in the cultivation of my small farm, that I should be now at a loss how to do without them. They pack better if collected when somewhat damp, and when mixed or chopped with the dung, will more readily ferment.'

"Perhaps there is a good deal of small stuff scattered over the farm that will serve for fuel, which may as well as not, and a good deal better, be picked up now, before it is hidden by snow—which latter, though, perhaps, not very soon expected, may come without warning, and when little anticipated. At any rate, it is wisdom to prepare for emergencies.

"Let everything be saved for winter fodder that is eatable by your animals. 'We hear it foretold by our veteran farmers, (says the American Agriculturist,) that the coming winter will be a tolerable severe one. They say they have never seen a season of great abundance, especially in fruit, that was not followed by a hard winter.' Though little faith is to be had in such signs, it is best to prepare for the worst, and save everything to lengthen out your stock of food, that can be saved. Some vegetable substances which cattle will not eat *alone* if they can get more palatable food, they will freely devour in winter, if mixed and chopped with a portion of eatable hay.

"Turnip and cabbage leaves, and corn husks, should all be husbanded for fodder. They are superior as food for cattle, to hay of common quality.

"We have seen pumpkins left in the fields to rot, the farmer having, seemingly, grown more than he knew how to dispose of with profit. At one of the meetings of the New York Farmers' Club last summer, a gentleman presented some sound pumpkins of the growth of the previous year, which had been preserved by placing them in one of his out-buildings on rails laid in courses, so that the pumpkins did not rest on each other. This plan seems worthy of trial: for stock—cows in milk especially—would be much benefitted, by a meal a day of pumpkins, in the last of winter or beginning of spring—more especially if their owners do not provide other *condiments* for them in the shape of carrots, turnips or beets; and it is yet true—'and pity 'tis true'—that many a stock of unfortunate animals have to live through, or rather get through, the winter, without having a taste of a root—kept upon the *low diet* system—the *Graham* system in an aggravated form—that is, a *few* cornstalks, a *very little* good hay, and a *great deal* of—straw. Pity that the poor brutes thus cheated of their dues, had not the faculty to persuade their owners that both self-interest and humanity dictate that they should keep no more stock than they can keep *well*.

"Your sheep will thank you for saving your bean vines for a bite in the winter; and in this connection we introduce the following, thinking it may impart information from which some may profit:

"'*Beans for Sheep.*—If you have any beans on hand which are unfit for culinary purposes, in consequence of being mouldy or rancid, wash them carefully and give them to your sheep. A gill a day will be of more benefit to them than a pint of corn. Beans, for sheep, even in this condition, we consider equal to the best corn in any state.—*Maine Cultivator.*'

"Upon the above, Dr. Lee, of Buffalo, remarks: 'The Cultivator tells but half the story. *Why* is a gill of beans better for sheep than a pint of corn? This is an important problem, and one that not one flockmaster in a thousand can answer. If the object be to form fat sheep, then the remark that beans are worth more than corn, is not true—for corn contains more of the fat-forming elements than beans. But if the object be to form *muscle* and *wool*, then the remark is true. Beans contain more of the element of wool than any other cultivated plant. Hence nature, ever true to herself, has endowed the sheep with a taste for the plant which is denied to the pig.'"

From the American Farmer.

ACCUMULATION OF MANURES.

The following article has many suggestions by which the farmer may profit, and although written for the meridian of Maine, is equally as applicable to any other State in the Union where there are worn out lands. It is unfortunately the case everywhere among farmers in this country, that the procurement of manure is not made a part of their system of husbandry; and that a too-common opinion prevails, that they cannot spare the necessary time and force to gather the materials for making manure. Than this, a more erroneous opinion never entered into the mind of man. We have thought much upon this subject, and had some little experience, and we have no hesitation in declaring, that a man and a team employed the year round in the collection of materials for forming manure heaps, would add fifty per cent to the producing capabilities of any farm—nay, we will go farther and say, that if such materials, when collected, were judiciously composed and preserved, that they would make every cultivatable acre of impoverished land increase its yield a hundred per cent. Where farms may lie upon salt water rivers, with salt marshes attached, the supply of manures are not only inexhaustible, but of the very best character, where the proper pains were taken to procure the *mud* and either compost it, or spread it over the cattle yard, as besides the vast amount of vegetable remains, the saline matters found therein are of the very first importance.

From the Maine Cultivator.

MANURE.

MESSRS. EDITORS:—Very few farmers, comparatively, are to be found who make any efforts at all to increase either the quantity or the quality of their manure. The subject is a very important one, and it is to be hoped that farmers will, ere long, become not only thoroughly convinced of the importance of attending to the manure heap, but that they will do something more than to *talk* of the excellency of manure.

Now it does not require a large capital in order to make an abundance of manure—it requires only a *firm* resolution, a good yoke of oxen, a good cart, a good wheelbarrow, and a good spade. We do not expect to see every farmer in moderate circumstances build a splendid stercorary, but then every farmer may make a compost-yard of his barn-yard and may double or treble the quantity, and also improve the quality of his manure. It would be well if every barn-yard were shaped somewhat like a milk-pan, sloping every way towards the centre; but if a farmer cannot afford the expense of bringing his barn-yard to the right shape, he can, at least, haul a few loads of dirt, and form a dam at the lower part of the yard to prevent the liquid portion of the manure from escaping.

Instead of suffering the liquid part of the manure of the barn-yard to escape, we should move the wheelbarrow, and supply a sufficient quantity of materials to absorb the same.

But who has thought highly enough of our *swamps?* Who can calculate the amount of muck or mud to be found in the State of Maine? If this valuable material can be rightly managed—if our farmers, one and all, will make strong efforts every year to procure this material from swamps, pond holes, from the brooks and other places, what a change may be wrought in our agriculture!

Suppose that a farmer by driving forward his business and making a proper improvement of time can be able to spare three weeks in the course of each year, in collecting materials for manure—what effects will this have upon his prosperity? How much manure will a farmer who like Farmer Thrifty is a man of energy collect in eighteen days—at only six loads per day it will give one hundred and eight loads—let this be thoroughly mixed with the manure of the barn yard, the stable, the sheep-pen, and the hog-yard. When clearing out the manure of a barn-yard let a quantity of mud, &c., be placed upon the bottom Let us also cover over the animal manure with loam, turf, mud, &c. so that it may not escape. When digging over manure let us not forget to cover the same with some material calculated to prevent the precious matter from escaping into the atmosphere.

It has been often asserted that one load of animal manure will ferment three loads of peat—this is a substance which is to be found in swamps, and differs from mud or muck. It must be more of a task to bring peat into the right condition to operate well as manure than mud or muck.

It is easy enough to see that every farmer who can find mud or muck, &c., may double or treble the quantity of his manure at a very trifling expense. Those who may not happen to reside near some swamp may certainly procure at least a considerable quantity of rich matter in waste places by turfing the highway, &c. But suppose that a farmer cannot get materials enough to satisfy his ambition, he can add to his manure by plowing in green crops. Various modes of plowing in crops for

manure have been recommended. Plowing in grass stuble immediately after haying, and sowing in fresh grass seed, is one excellent method of improving the soil. If grazing lands that are cleared of obstructions to the plow were managed in the same way the farmer will find his labor to be well applied. Plowing in crops of clover at full length, and the using of Plaster of Paris to aid the growth of the clover should in some cases be practiced. Every farmer should take an agricultural paper, and these should give out to the people in plain, unvarnished language the necessary knowledge. If young lawyers multiply upon us and contrive by vile intrigues to sit in high places and hold agricultural skill and industry in the most sovereign contempt, there will yet be found a "redeeming spirit in the people." J. E. R.

Rumford, September, 1844.

CARRIED AWAY BY INTENSE FEELING.—An anecdote of the Attorney General of Massachusetts is told in a late Boston paper. The worthy old gentleman must have been completely carried away by his feelings, yet who can blame him? Read the story:

The Attorney General, now eighty years of age, and said to be more competent to the discharge of the ardous duties of his honorable station than almost any practitioner, by experience, as well as a remarkable retention of mental power, was managing a case in behalf of the commonwealth in Middlesex county, where a man was indicted for gouging out the eyes of a girl, because she made oath that he was the father of her illegitimate child.

Her brother, an intelligent lad of nine years of age, was on the stand, as a government witness, and his relation of the fact which he saw produced an electrical effect on the whole audience. The girl was also present, in total blindness, and every circumstance attending the investigation of the horrible barbarity, was highly exciting. The boy stated the preliminary circumstance, and then said:

"I was cutting bean poles behind the barn, and my sister was milking. I heard her scream, and then I ran with a pole in my hand. As I came up I saw that he had pulled her over; then he looked over his shoulder, to see who was coming, and I struck him with the pole and broke his jaw."

"Why did you not repeat the blow?" exclaimed the Atterney General, carried away by the remendous interest—why did you not repeat the blow, and knock his d—d brains out?"

"Mr. Attorney," said the Judge, "you well know that profanity in court is a high offence, punishable with imprisonment: but in consequence of the unusual excitement of the case, it will in this instance be overlooked."

Mile.—There is a great difference in the number of yards contained in a mile in different countries. The following table, showing the difference will be very useful to many persons as a reference:

Mile in England or America	1760	yds.
" Russia	1100	"
" Italy	1476	"
" Scotland and Ireland	2200	"
" Poland	4400	"
" Spain	5028	"
" Germany	5866	"
" Sweden and Denmark	7223	"
" Hungary	8800	"

CUT AND COME AGAIN.—A lady passing through Chartres-street yesterday, whose dress, in diversity of hue and richness of coloring, resembled a peripatetic flower-pot, dropped, unknown to herself, from her bonnet a snow-white plume. A gallant—with a turf of hair on his chin as large as that on the scalp of a Crow Indian—who saw it fall, hastened to pick it up. Presenting it to her, he said—

"Madam, you have lost your wit; permit me to restore it to you—I say your wit, madam, because, you know, Pope says—

'A wit's a feather—'

Ha! ha! ha!" and he laughed at what he assumed to be his own smartness.

"Yes, sir," said the lady, taking her plume from him, "and the same author remarks, in connection with your quotation that—

'A fool's a rod—'

Now, excuse me, sir, if, while thanking you for my plume, candor compels me to say that I look upon you as the *greatest kind of a sapling.*' *Picayune.*

A SWINISH MULTITUDE.—The Cincinnati Chronicle says that at least 50,000 Hogs will reach that city this season from Kentucky alone. The larger portion of them have already arrived there.

One house in Cincinnati cut up two thousand Hogs one day last week.

TENDER MERCY.—The N. Y. Evening Mirror states that a gentleman of that city bought a piece of property some years ago, for $20,000. He paid $10,000 "down," and for several years the interest on the balance. The mortgage he had gave was foreclosed, the property was bought for a small sum and a decree entered for the balance, which was about $10,000. The mortgagee, not content with having his land back again and the $10,000, has filed what is called a creditor's bill, to see if he cannot find something more on which to lay his hands! This is the mercy which some creditors exhibit.

Successful Railroad Managemont.—The Philadelphia U. S. Gazette says that the business of the Western Railway, between Boston and Albany, will astonish many this season. The total revenue for 1842 was $522,688, last year $573,882, and this season it bids fair to reach one million dollars, being already $272,828 ahead of the amount received to a correspond ing period of 1843.

BACON'S LARD LAMPS.—A new article, superior to all others for this purpose, emitting a good clear light without smell or smoke, and at an expense, counting Lard at 8 cents a pound, of about a quarter of a cent an hour.

These Lamps have been satisfactorily tested, and are recommended as "just the thing" for the use of planters, and all others who study utility, neatness and economy.

A supply of the above Lamps, with Fillers and Wicks for them. For sale by

HAVILAND, RISLEY & CO.

TEXAS COTTON SEED.

THE subscriber offers for sale, Cotton Seed of very superior quality. The original stock was procured in Texas, and cultivated on his plantation in Newton county, for the last three years, with extraordinary success. The yield is much larger, and the quality superior to the Petit Gulph or other kinds of Cotton usually grown in this section of country.

Planters who purchase a supply of the seed may rely upon sufficient increase in product of the first crop to refund the outlay for seed.

Planters who take an interest in improvements of this sort, are referred to the annexed certificates, and the Cotton raised from the seed may be seen at the warehouses of Adams & Hopkins and Clark & Roberts.

JOHN W. GRAVES.

A supply of the above described Cotton Seed is offered for sale at the following places, at five dollars per bushel:

ADAMS & HOPKINS's Warehouse, CLARK & ROBERTS's do., D'ANTIGNAC & EVANS's do., HAND & WILLIAMS's Store, } Augusta.
McKINLEY & MARTIN's Store, Madison.
HILL, MORROW & HILL's Store, D. DICKSON & Co.'s Store, } Social Circle

Georgia, Newton County:

I hereby certify that I obtained from John W. Graves, of this county, a sack of Cotton Seed, (which he represented of superior quality introduced from Texas,) which I planted last spring, and find to exceed my most sanguine expectation. I planted it two or three weeks after my other cotton, (which is the Petit Gulph,) and notwithstanding the season was dry and unfavorable throughout the year (the growing season) yet it is by far the best cotton I ever made. I think by the time it is all gathered, the best part will yield 2000 to 2500 pounds per acre. My neighbors who have seen it are of the same opinion. From the trial I have made, I believe it will yield double as much as my other cotton on land of the same fertility [Signed] JACKSON HARWELL.

24th October, 1844.

Georgia, Morgan County:

This is to certify that I am neighbor to John T McNeil, Esq., and that he last spring got a load of Texas Cotton Seed from John W. Graves, Esq., of Newton county, and planted them on what I consider average land of his farm; and from frequent observation of the crop, with his other cotton, (which is the Petit Gulph,) I do believe it will far excel any other cotton I have ever seen raised in this section of country. And I also believe that the staple excels any other I have ever examined, as to fineness and color.

[Signed] JOHN P. EVANS.

This will certify that I acted as overseer for Mr. John T. McNeil for the year 1844. My knowledge of farming induces me to believe that the Texas Cotton, raised by Mr. McNeil this year, is a very superior article, and with me preferable to any other cotton I have ever raised. It is of long and fine staple, and well bolled, and easily picked out, and has withstood a drought this year better than the Petit Gulph Cotton. It is, in a word, a valuable cotton. I have ginned eight bales of the Texas Cotton on Mr. McNeil's *Carver Gin*, and find that it yields one pound of clear cotton from three of seed cotton; and from my experience of thirty years in cotton growing, I have never raised any I think equal to the Texas Cotton.

[Signed] ALLISON KENT.

AUGUSTA, October 30, 1844.

John W. Graves, Esq.:

Dear Sir—Having been called on by you to make a statement in relation to your Texas Cotton, we take pleasure in saying, that for the last two or three years we have received at our warehouse your cotton crops. The quality has invariably proved very superior, both as to color and length of staple. On sale, it has always brought the highest market price. We consider it a very superior article in the cotton line.

Your obedient servants,

ADAMS & HOPKINS.

Mr. John T. McNeil:

Dear Sir—We have received the two bales of Texas Cotton sent by you to us, and take pleasure in saying that in color and length of staple it is superior to anything we have seen; and cheerfully recommend it as such as will always bring the highest market price.

Your obedient servants,

n5-wp&Ctf CLARK & ROBERTS.

PRINCE'S

Linnæan Botanic Garden and Nurseries,

FLUSHING, L. I., NEAR NEW YORK.

THE New Descriptive Catalogues (which have *cost* over $700) of the TREES, PLANTS, and SEEDS at this Establishment, will be sent gratis to every *post paid* applicant by addressing

WILLIAM R. PRINCE & CO.
